AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.
It is unequalled for cleaning Woolen Fabrics, Cutlery, Carpets or Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing.
It renders water soft, and imparts a delightful sense of coolness after washing.
DIRECTIONS.—For Laundry, use two to four table-spoonfuls to a wash-tub of water. For bathing, use one table-spoonful in the bath-tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterward. For stimulating the growth of plants, use a few drops in every pint of water used in watering.
PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.
Also, SULPHATE OF AMMONIA for chemical purposes; fertilizing; and the preparation of artificial manures. AMMONIACAL PREPARATION for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing, and PURE LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes.

ASSAYERS' MATERIALS

—AND—

Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.
Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in Grains Grammes, will be sent free upon application.
7v25-tf JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.
They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces.—Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco

Miscellaneous Notices.

This is a Sure Cure for Screw Worm, Scab and Foot Rot in Sheep. It also kills Ticks, Lice, and all Parasites that infest Sheep.

Prevents scratching and greatly improves the quality of the wool. One gallon of the Dip properly diluted with water will be sufficient to dip one hundred sheep, so that the cost of dipping is a mere trifle, and sheep owners will find that they are amply repaid by the improved health of their flocks.

This Dip is guaranteed to cure when used according to directions, and to be vastly superior to Corrosive Sublimate, Sulphur, Tobacco, and other remedies which have heretofore been used by farmers.

Circulars sent, post paid, upon application, giving full directions for its use, also certificates of prominent sheep growers who have used large quantities of the Dip, and pronounce it the most effective and reliable known Cure and Preventive of Scab and other kindred diseases in Sheep. mrl3-hp

Ayer's Hair Vigor

RESTORING GRAY HAIR TO ITS NATURAL VITALITY AND COLOR.

Advancing years, sickness, cure, disappotment, and hereditary predisposition, all turn the hair gray, and either of them incline it to shed prematurely.

AYER'S HAIR VIGOR, by long and extensive use, has proven that it stops the falling of the hair immediately, often renews the growth, and always surely restores its color, when faded or gray. It stimulates the nutritive organs to healthy activity, and preserves both the hair and its beauty. Thua brashy, weak or sickly hair becomes glossy, pliable and strengthened; lost hair regrows with lively expression; falling hair is checked and established; thin hair thickens; and faded or gray hair resumes their original color. Its operation is sure and harmless. It cures dandruff, heals all humors, and keeps the scalp cool, clean and soft—under which conditions, diseases of the scalp are impossible.

As a dressing for ladies' hair, the Vigor is praised for its grateful and agreeable perfume, and valued for the soft luster and richness of tone it imparts.

THE TURBINE.

Simplest: Cheapest

Most Durable

THE INVENTOR OF THE

DEXTER WINDMILL

Has made new and useful improvements in Windmills,
and now feels confident of having the SIMPLEST,
CHEAPEST, MOST DURABLE, and

ONLY PERMANENT WINDMILL IN THE WORLD.

SIMPLEST, because it is less complicated; CHEAPEST,
because it never needs repair, standing on a firm founda-
tion. MOST DURABLE, because it is all under cover,
and has less rigging to get out of order; ONLY PERMA-
NENT, because the only Windmill in the world that has
never been injured by storms. Hundreds of people,
who have thought the Dexter perfect will be glad to
observe the SUPERIORITY OF THE TURBINE over
all predecessors. Although much improved, the price
of mill remains the same as formerly. Persons who
study their own interest will investigate the TURBINE
before purchasing any other.

Territory for sale outside of California, at reasonable
rate and easy terms.

TO COPPER SMELTERS, BLUE-STONE and Sulphuric Acid Manufacturers.

For sale or to lease, the LEVIATHAN COPPER
MINE, in Alpine county, California.

The ore, which is in the form of alluvial, black and
red oxide, and gray sulphide, with metallic copper
finely disseminated, averages from two to five feet
thick, and 15 to 50 per cent. copper. A few parcels
taken out during exploratory operations realized \$30,-
000 for Bluestone. In sight, 2,000 tons 20 per cent. ore;
on dump, 800 tons 15 per cent. Supply inexhaustible.
Title perfect. Minimum present capacity, 10 tons per
day, which may be extended indefinitely. Cost of
extraction, \$1. There is also a stratum of sandstone 20
feet in thickness, impregnated with 26 per cent. of
pure sulphur. To a coin purchaser highly advantage-
ous terms will be offered. For further particulars
apply to Louis Chalmers, Silver Mountain, Alpine
county, Cal.

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR
APPLICATION—requiring no thinner or dryer, and will
not spoil by standing any length of time.
It is Cheaper, more durable, more Elastic, and pro-
duces a more Beautiful Finish than the best of any
other Paint.

It will not Fade, Chalk, Crack, or Peel off, and will
last twice as long as any other Paint.
In ordering White, state whether for Outside or In-
side use, as we manufacture an Inside White (Flat) for
inside use, which will not turn yellow, and produces
a finish superior to any other White known.

Put up in 1/2, 1, 2 and 5 gallon packages, and in
Barrels. Sold by the Gallon.
For further information send for Sample Card and
Price List, or apply to the office.

The Screw Propellor.

The following paper was read by W. W. Hanscom, of the Hope Iron Works, at the meeting of the Society of Engineers of California, held April 6th. The paper will be discussed at the next regular meeting:

"During my experience and study of the screw as a means of propulsion of steam vessels I have endeavored to find expressions which would approximate to a certain value in the efficiency and power required to propel vessels at any given speed, the displacement being fixed. So far in my investigations I find formulas which, in order to approximate to the power required for a given speed, insist on a deeper knowledge of higher mathematics than is possessed by many men of sound judgment, whose very opinion will come nearer to the actual duty performed and power required than the so-called formulas. Not that formulas should not be employed, but so many terms are called into use in their evolution that they become intricate, and oftentimes, I think, more unreliable than the so-called rules of thumb, which have come into common use for approximation; and also, I think, what may be called false terms are brought into requisition, which do not have any necessary bearing on the question, and only serve to make more complex the solution of a question so important.

In this paper I propose to speak particularly of only one or two points in the screw propeller, and those are the proportion which the area of the screw's disc bears to the immersed midship section, and the importance of sectional lines. "At another time I shall speak of the pitch and velocity. I believe that some very erroneous notions have crept into the heads of designers and owners of screw steamers, and while I treat with respect the opinions of others, I shall endeavor to give some reasons for the ideas which I have respecting the diameter of screw, at present a general standard, I believe, of first-rate speed at sea. I mean the average of a voyage is about ten knots, and in order to make the comparison which I have intended the speed to that rate. Although at some future time the speed of vessels may be increased much beyond that, and even now vessels are doing it, yet not many, I think, on the coast of California and Oregon, are exceeding it.

It is commonly supposed, and the theory is advanced by well-known writers on the screw propeller, that the larger the diameter of the screw the more will be its effect in proportion to the power consumed; therefore, they say, get the screw's diameter as large as possible.

But such is not the fact, and I take it for granted that the immersed midship section may bear to the area of the screw's disc, indifferently, any proportion between four to one and two and one-half to one, without impairing its efficiency—that is, the area of the immersed midship section may be anywhere between two and one-half and four times the area of the screw's disc, and its efficiency for the power will be the same, or, if there be any advantage, it will be in favor of the smaller diameter. I am assuming now a vessel with any certain displacement and proportion of length to breadth; that, too, being an element of not as much consequence, I think, as has been given it; and in examining the results of trials of steamers in the British navy this becomes palpable.

To show the indifferent effect with given power, I will take the British war steamer, *Archer*, whose general dimensions are as follows: Length, 186 ft., 4 in.; beam extremes, 33 ft., 10 in.; draft of water, 13 ft., 3 in., forward, 14 ft., 11 in., aft; displacement, 1245 tons. This vessel's length was about five and one-half times her breadth, and on one trial the proportion of immersed midship section to the area of the screw's disc was 3.03, and at a speed of ten knots the proportion of power to displacement was .63 per cent.—that is, for each ton of displacement .63 of a horse-power was required for a speed of ten knots.

When the diameter of the screw was reduced so that the immersed midship section was 4.68 times the area of the screw's disc, then the power required was reduced to .57 per cent., or a saving of six per cent., showing that a smaller diameter of screw has made the vessel more efficient. At a given speed and all the periphery of the screw travels the same distance through the water, no matter what may be the diameter, therefore the smaller the area of the screw's disc can be made—within certain limits, which are not yet closely defined—the less will be the frictional resistance to the water on the wheel, and consequently the more is there realized in the percentage of the net horse power.

One of the reasons which I assume for this is the fact that the resistance of a vessel does not entirely depend on the sharpness of her water line, as is commonly supposed. I am aware that I am making an assertion which is in direct opposition, or nearly so, to many preconceived notions concerning the fineness of the water lines of propellers, both entrance and leaving, or, in other words, the relative sharpness of the bow and stern.

The resistance of a vessel varies with her size, and inversely in a nearly certain proportion to the displacement. For instance: Tak-

ing a speed of 10 knots, a vessel displacing from 7,000 to 8,000 tons will require about .23 of a horse-power indicated for each ton of displacement. A vessel displacing 5,000 tons will require from .32 to .35, horse-power for each ton of displacement; 3,000 tons from .40 to .45 horse-power for each ton of displacement, and a vessel of 2,000 tons will require from .50 to .60 horse-power for each ton of displacement. Vessels of 1,000 tons require from .60 to .70 horse-power for each ton displacement, and in this connection I will state that there seems to be not much of any difference whether the length of vessel is $4\frac{1}{2}$ or $6\frac{1}{2}$ times the breadth of beam. The power required varies but little, so that there must be something in the economic propulsion of steamers besides the comparative proportions of length and breadth and inverted midship section to the area of the screw's disc. One point here is that which I find has been entirely overlooked, or at least I have never seen it referred to, and that is the shape of the sectional lines of a vessel, which are of really much more importance than the shape of the water lines; in fact, no particular attention need be paid to the extreme sharpness of the water lines, provided the sectional lines are shaped properly. By sectional lines I mean vertical planes cutting the vessel longitudinally from end to end, at various distances from the center of the keel. With merchant steamers, especially, it is desirable to use the least fraction of horse-power per ton of displacement for a given speed, and all the efforts have been apparently in the direction of extreme length to breadth, so that the water lines or horizontal planes cutting the vessel longitudinally may be, as they are called, easy. This comes from the fact that the motion of the water, when a vessel is passing through it, is assumed to move almost entirely in a lateral direction, and no apparent heed has been given to its vertical motion.

Mr. John Bourne, in his able treatise on the screw propeller, seems to have overlooked this important fact, as well as the comparatively small difference in the relative efficiency of long and short vessels, for he states in his work on "The Screw Propeller" that the resistance increases in different proportions with long and short vessels, compared to their breadths, and his expression that "the superior efficacy of long screw vessels over long paddle steamers is mainly imputable to the partial recovery of power by the screw"—shows that the after body of propeller steamers have usually been so proportioned that the water has not had free access to the wheel in a solid body, thereby allowing the screw to create centrifugal action in the water, throwing it up against the stern and raising a hill of water down which the vessel slides. The very fact of the settling of a vessel by the stern when under way seems to prove that the support is partially taken away, while at the same time the water at the bow is raised up by its inability to pass under the vessel easily, assisting at the same time to raise the forward part. And especially under these circumstances should the screw be made comparatively small in diameter, that it may only act on the column of solid water which may come under the vessel in the most direct line to the screw. In calling your attention to this point, and also to the importance of proper sectional lines, I have no doubt you will be able to explain the comparative speed of some very flat vessels, which have quite full water lines.

The English war steamer *Aboukir*, of 3,150 tons displacement, and whose length is only 3.4 times her breadth, requires .5 of a horse-power per ton of displacement for a speed of 10 knots.

The *Aurora*, 3,498 tons displacement, with a length 4.53 times her breadth, requires .42 of a horse-power for each ton displacement, a difference of .08 of a horse-power for each ton of displacement, a difference of about 27 horse-power, or less than two per cent. of the total horse-power required for a vessel whose length is only 3.4 times her breadth.

The *Bombay*, whose length is 4.47 times her breadth, requires with a displacement of 3,020 tons, .47 of a horse-power for each ton displacement; and the *Algiers*, whose length is 3.65 times her breadth, requires .34 of a horse-power per ton of displacement; while the *Arctusa*, whose length is 4.79 times her breadth, requires with a displacement of 2,801 tons, .46 of a horse-power for each ton. The *Arrogant*, whose length is 4.37 times her breadth, requires .55 of a horse-power for each ton of displacement.

These records of trials made under the most favorable circumstances for accuracy, indicate that considerable variation, so far as proportion of length to breadth is concerned, does not affect the power required, and that there is some other point of more importance to examine, and that, I think, will be found in the sectional lines—that is, when the length of the vessel is proportioned to her draft, so that easy sectional lines can be formed with even a short floor, then the power does not materially vary with variations in the length, the breadth, or the variations of the area of the inverted midships action to the area of the screw's disc, of course within certain limits, which are yet to be determined.

In conclusion I would state that all the experiments which have yet been made tend to prove that there is very little economical difference between a true screw and those of the most elaborate design and construction, and not as much as there is between wheels of fair lines and smooth surfaces, and those whose surfaces are rough and lines unfair.

Mechanics' Institute—Tenth Industrial Exhibition.

The annual exhibitions under the auspices of the Mechanics' Institute of this city have become among the most notable events in our local history, and every succeeding year are looked forward to with increasing interest. Each exhibition surpasses the preceding in the number and value of articles displayed, and the popular interest is evinced by the increased attendance which marks its occurrence.

The opportunity offered by these exhibitions for making known the great value of our natural productions, and the skill achieved by our artisans and mechanics in utilizing them is manifest, and one that is not lost sight of by our manufacturers, miners and agriculturists. Last year the increased demands for more room and larger facilities resulted in the erection of the mammoth pavilion in which the ninth annual exhibition was held. This building, situated on Eighth street between Mission and Market, is, we believe, the largest devoted to a like purpose in the United States, and will have its only equal in the structure to be erected in Philadelphia to mark the centennial of our national existence.

The pavilion as originally constructed has a frontage on Mission street of 201 feet, and the same on Market. The length of the building is 541 feet on Eighth street. It contains 6,287,000 cubic feet of space between its walls, has four acres and a half of flooring, and cost upwards of \$100,000 in gold. To this mammoth structure there is now being built on the north side an addition to be known as the Horticultural Garden. At the last exhibition the horticultural and floral display was arranged in the side of the pavilion at the right of the entrance in front of the department especially devoted to machinery. Although the display in both these departments was creditable, the management felt that each was more or less trenching upon the other, and consequently have reserved all the lower portion of this side of the building for machinery, giving two hundred feet additional for that department, the shafting being extended the whole length, affording vastly better facilities, which, no doubt, will be duly appreciated by our manufacturers, and result in a much finer display than in any previous year. The Horticultural Garden is an addition two hundred feet in length by a width of seventy-five feet. The sides are constructed of wood, but the roof, instead of being like the pavilion proper, is covered with canvas stretched upon the arched timbers. This arrangement is believed to be in many respects superior for the purpose for which the Garden is designed. Although not nearly completed, progress is far enough advanced to afford an idea of what the visitor will realize when he comes to see the interior prepared for his reception. A broad entrance from the pavilion leads into the Garden. Fifty feet of the front, extending the entire width, is paved with tile of varied tints, and will be set apart more especially for the pomological and floral display; the fruit, out flowers, etc., being placed upon tables arranged for the purpose. A descent of two steps and the main walk dividing passes around a circular enclosure, in the center of which a fountain will be located. Other walks are being laid out, fountains and rockeries arranged, and the whole interior heightened and adorned with the choicest shrubs, plants and flowers. The Garden will be under the direct control of the Institute, and to give the public an idea of what they may expect, it is but necessary to add that the plan of arrangements is the work of Mr. A. P. Hall, the well known landscape architect, and that Mr. R. B. Woodward is Chairman of the Committee in charge. The additional space under cover acquired by the construction of the Garden is 24,500 feet. Three thousand square yards of canvas will be used for the roof.

Last year the exhibition was attended by 700,000 visitors, and there is reason to believe that the number will be nearly doubled at the one this season, and a good portion of these visitors will be new-comers. It is therefore for the interest of our producers and manufacturers to exert themselves to make a display which will be a credit to them and to the resources of our State. It has been decided to award premiums to exhibitors as follows, viz.: 16 gold medals, 50 silver medals, a Society diploma, certificates of merit, and special premiums as the Board may determine.

The exhibition will open on the 17th of August at 11 A. M. Mr. J. H. Conner, the courteous and competent Secretary of the Institute, is prepared to receive applications for space and afford information to parties interested. He may be addressed or can be seen during business hours, at his office, 27 Post street.

We earnestly hope that the tenth annual exhibition of the Mechanics' Institute may prove a worthy reflex of the wonderful growth and prosperity which marks the career of the Golden State.

In the Lady Washington mine, on the Comstock, the heavy body of water encountered being found difficult to reduce with present appliances, it was concluded to not attempt to contend with it until a first-class pump can be brought to bear in the case. The water is now 120 feet deep in the shaft, but will have to get out of that in due time.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DREW & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., April 13, 1875.

FOR WEEK ENDING MARCH 30.

STEAM GENERATOR.—Sabra R. Mathewson, Gilroy, Cal.
ROTARY REVERSING AND CUT-OFF VALVE.—John C. H. Stint, S. F., Cal.
ORE CRUSHER.—David Trumbull, Jr., Contra Costa, Cal.
GAGE QUILTER AND CORDER.—George Vincent, Stockton, Cal.
GUIDE ATTACHMENT FOR SEWING MACHINE PRESSER FEET.—George Vincent, Stockton, Cal.
FIRE ALARM REGISTER.—Daniel T. Phelps and Charles W. Edmunds, S. F., Cal.

TRADE-MARK.
FOR PREPARATION TO BE USED ON SHEEP.—Redington, Hostetter & Co., S. F., Cal.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.
NOTE.—Copies of U. S. and Foreign Patents furnished by DREW & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with effect security and in the shortest possible time.

MINING PATENTS ISSUED.—The following mining patents have recently been issued:

California.—Alpine county—Lady Franklin silver mining company, Lady Franklin gold and silver quartz mine. Butte county—D. C. Baldwin, Murphy's ravine diggings. N. D. Rideout and Wm. S. Smith, Porter quartz mine. El Dorado county—C. Weisell and J. N. Nicolvison, Last Chance quartz mine. Levi Shepard, Rose quartz mine. Nevada county—B. D. Evanport, Eagle quartz mine. Mono county—S. A. F. Bryson and Geo. R. Porter, Dunderberg mine. Yuba county—J. P. Brown et al., Nevada mining company's placer. Napa county—J. M. Hamilton et al., Napa Quaker mine, quicksilver.

Nevada.—Eureka county—W. W. McCoy, Ione and Grant lodes.

Oregon.—Baker county—Charles Green, Monumental lode.

Utah.—Salt Lake county—General Hardie, Fairview mine. B. M. Durell et al., Kempton mine. Tooele county—E. H. Shaw, Last Chance mine. E. S. Blackwell, Miners' Delight mine. Box Elder county—Lloyd Aspinwall, Morning Star, Rising Star, Red Cloud, Independence, Confidence, Empire, and Tecoma mines.

The New English Patent Bill, introduced by the Lord Chancellor into the House of Commons, will probably, with some modifications, become a law. The subject of patent reform has been debated in England for about fifteen years, and this bill will probably prove the first step of the English Government towards the American system of examination previous to granting patents. We would call attention to the fact that it is provided that an application for an English patent must be made within six months after the date of a patent for the same invention granted in any other country. Those who have American inventions already patented here, and which they desire to patent in England, will be deprived of the privilege if at the time the new law goes into force their American patents shall have been issued six months.

The Segregated Gold Hill, on the Comstock, is an old location west of the Imperial, formerly worked to good advantage, but after lying idle through indifferent and bad management, it is now, under new hands, being brought out right. The old shaft, which is about 400 feet deep, will be made available.

The "Prospect," an old location on the Comstock, lying about 3,000 feet west of the Occidental, after lying idle for some years, is now to be worked. A large new working shaft of three compartments is now being started about 1,000 feet east of the croppings.

SYMPTOMS OF CATARRH.

Obstruction of nasal passages, discharge falling into throat; some times profuse, watery, acid, or thick and tenacious, mucous, purulent, bloody, putrid, offensive, etc. In others a dryness, weak or inflamed eyes, ringing in ears, deafness, ulcerations, scabs from ulcers, voice altered, nasal twang, offensive breath, impaired smell and taste, &c. Few only of these symptoms likely to be present in any case but one.

To cure take Dr. Pierce's Golden Medical Discovery earnestly, to correct the blood and system, which are always at fault also to act specifically, as it does, upon the diseased glands and lining membrane of the nose and its communicating chambers. The more I see of this odious disease, the more positive is my belief that if we would make treatment perfectly successful in curing it, we must use constitutional treatment to act through the blood, as well as a soothing and healing local application. Dr. Sage's Catarrh Remedy, when used warm and applied with Dr. Pierce's Nasal Donche, effects cures upon common sense, rational and scientific principles, by its mild, soothing and healing properties to which the disease gradually yields when the system has been put in perfect order by the use of the Golden Medical Discovery. This is the only perfectly safe, scientific and successful mode of acting upon and healing it.

Discovery, Catarrh Remedy and Donche are sold by dealers in medicines the world over.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

IMPROVED HOISTING ENGINES.

HOISTING ENGINES.

SEND FOR
Descriptive Circular
and Prices.

COOK, RYMER & CO.'S Celebrated Hoisting Engines have been too long in use on the Pacific Coast to require any special recommendation from us. We refer with confidence to any one of the hundreds now in use. We simply state that they still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship for the sake of competing with cheaper engines. For details of sizes send for price list. We desire to call particular attention to our new

MINING HOISTING ENGINES.

(Manufactured by the same parties.)

Which have just been introduced on this Coast. The plans and specifications are the combined efforts of our most successful MINING ENGINEERS, and the result is the most complete

DOUBLE-DRUM HOISTING ENGINE

Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. One of these engines may be seen at work in the Belcher mine, and one in the Ophir, on the Comstock lode, to both of which we refer. We have all sizes of these engines constantly on hand. Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

(PATENTED MAY 26TH, 1874.)

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not outwear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to
1v29-3m

THE AMERICAN
TURBINE
Water Wheel.

Power Pledged Equal to
any Over-shot Wheel
Ever Built.

Recently improved and submitted to thorough sci-
entific tests by James Emerson, showing the following
useful effect of the power of the turbine utilized, being—

THE HIGHEST RESULTS EVER KNOWN.

Percentage of part gate, $\frac{1}{4}$ 60.08; $\frac{1}{2}$ 69.64; $\frac{3}{4}$ 78.73
 $\frac{1}{2}$ 82.53; $\frac{3}{4}$ 82.90. Percentage of whole gate, 83.14.

Mr. Emerson says: "These are the best aver-
age results ever given by any Turbine Wheel
in my experience."

A splendidly illustrated descriptive catalogue, or any
further information desired, furnished on application to

NEW ALMADEN QUICKSILVER.

TRADE A MARK.

The well known full weight and superior quality of
the Quicksilver produced at the New Almaden Mines,
having induced certain unscrupulous persons to offer
their inferior productions in flasks having our Trade
Mark "A," notice is given to consumers and shippers
that Quicksilver, A brand, guaranteed weight, can be
purchased only from THOMAS BELL, or his duly ap-
pointed sub-agents.

J. B. RANDOL, Manager,
New Almaden, April 5th, 1875.

SANTA CLARA, CAL., April 6th, 1875.
Messrs. Dewey & Co.—Gents:—We have just received
Patent No. 180,545, for J. T. Watkins & Co's Mammoth
Road Grader, which was patented through your Agency.
It is the nearest and best that we have ever re-
ceived. We feel proud of it and thankful to you for the
care and attention that you have given it, and when
we have anything to do in that line of business we will
surely give you a call. Very respectfully,
J. T. WATKINS & Co.

LOOK TO YOUR INTEREST!

MANUFACTURED BY THE

PACIFIC RUBBER PAINT

COMPANY.

For many years chemists and others have experi-
mented in mixing India Rubber with Oil, Lead, etc.,
in order to produce a perfectly

WATER-PROOF PAINT.

And at last successful in their effort, have formed a
chemical combination of Rubber with oil paints,
which when applied becomes hard and elastic enough
not to crack or peel, from the action of the atmosphere,
with a gloss equal to work finished with varnish. The

Pacific Rubber Paint Company,

Of San Francisco, California, together with the RUB-
BER PAINT COMPANY, of Cleveland, Ohio, own all
the patents covering perfect combinations like the
above, which is known and sold by them as "Rubber
Paint."

The great demand for the Rubber Paint induced this
Company to purchase of the Cleveland, Ohio, and New
York Rubber Paint Company, the patents for this
coat, and are now manufacturing this paint in all col-
ors, in large quantities, and have put the price below
the best lead and oil paints. The Rubber Paint is
prepared in Pure White, in all Cottage and other
colors, comprising any number of different shades and
put up ready for use, being a great advantage, as it can
be spread by any one.

It Flows From the Brush Freely, Works
Easily, and Settles Promptly. It is avail-
able for all kinds of Painting,

And may be used with equal advantage on iron, stone,
wood, brick, or plaster.

The Rubber Paint will cover more surface, cover it
better, and last much longer than Lead and Oil. Two
coats of the Rubber Paint is better than three coats of
Ordinary Paint.

SAN JOSE, CAL., March 20, 1875.

PACIFIC RUBBER PAINT Co., San Francisco.—Gentle-
men:—I have used and sold the Rubber Paint in this
city during the last four years. We have about one
hundred buildings painted with the Rubber Paint.
Among the prominent ones are the Etate Normal School,
Gates Institute, City Market; the residence of Josiah
Belden, J. W. Hinds, President Gold Note Bank, J. R.
Arquello, Santa Clara, etc. It has never failed to give
satisfaction, with a test of from one to four years, so
that its durability has been well tested. My sales last
year were nearly five thousand gallons.

Truly Yours, AMASA EATON.

Fitts' Improved Road Steamer.

To move over a common earth surface by means of steam, without rails, is not an easy problem to solve; and a machine to accomplish this feat and at the same time perform labor, must combine lightness, compactness, traction and a perfect control. A machine which the inventor claims combines these characteristics, is shown in the accompanying engraving. The

hands of steel, in the rims of the driving wheels, gives the most perfect traction of the driving wheels to the surface and at the same time furnishes all the elasticity necessary for a machine of this kind. The small steam pump placed upon the top of the tank, and working independently of the engines, will draw the water from a well or pond, fill the tank, feed the boiler, or throw the water out of the tank to a height of 50 or 60 feet.

The connection of the guide wheel with the driving shafts in such a manner that the steam

WRITER'S ASSISTANT.—A shorthand reporter suggests that an arrangement of some kind for moving paper along at intervals so as to present a blank surface to the pen or pencil of the writer, would be very useful. The apparatus should also have a guide for the hand of the writer, and should not only move to the left but up from the hand. It seems that something of this kind is within the possibilities of mechanical construction. All who have much

Plumbago.

Several veins of plumbago have recently been discovered in the vicinity of Columbia, Tuolumne county. The *Independent* says but little is yet known of their true value; but specimens have been sent to Nuremberg, Bavaria, where the celebrated Faber lead-pencil factory is located, to have their merits passed upon. The *Call* says that it is believed that the articles will

THE AMERICAN ROAD STEAMER.

cut shows two views of the American road steamer, taken from a photograph of the America.

These steamers may be built of different size and capacity. The dimensions of the one shown—the *America*—are as follows: Boiler, 38 inches by 6 feet 6 inches; driving wheel, 66 inches in diameter by 10-inch face; guide wheel, 31 inches in diameter by 6-inch face; cylinders, 7 inches in diameter by 10-inch stroke; capacity of water tank, 250 gallons; of full bunkers, for 10 hours labor; width of track, 76 inches; length of steamer, 10 feet; total weight, ready for labor, about five tons; pulling capacity, 15 to 20 tons upon tracks.

These steamers are designed and built with special reference to their adaptation to all the various uses that a self-moving power may be applied, such as hauling heavy loads, plowing, reaping, threshing grain, sawing wood, etc. The inventor claims that the arrangement of the rubber blocks in pockets, surrounded by

will turn this wheel in any direction by simply moving a lever, places the steamer under easy control of the driver. By blocking up the driving wheels and placing a band upon them, the machine is converted into a stationary engine, and may be used as such for any purpose desired. These engines are geared to about three miles working speed, but this may be increased by giving the cylinders more steam. The inventor states that the supply of fuel for the *America* for ten hours' labor is 500 pounds of coal, but the consumption of course depends upon the size of the steamer and the amount of labor performed. Arrangements have been made with the Baldwin Locomotive Works for the construction of these machines, and they can be furnished at short notice. The inventor is desirous of introducing these engines in the mining sections for trucking and other work. Those desiring further information on this subject can address George W. Fitts, 333 Walnut street, Philadelphia.

writing to do in the way of note-taking would find it a great convenience to have something of this sort, which would enable them to write rapidly, and at the same time keep their eyes on the witness, lecturer or other speaker. The apparatus would have to be light, portable and simple in construction. It should also be capable of quick adjustment, to move fast or slow according to the requirements of the occasion. Now that we have writing machines, it does seem as if such an apparatus as we speak of would not be difficult to construct. Here is a chance for some ingenious individual to try his hand on an invention.

A new side branch of the railroad to deliver machinery and supplies at the Caledonia mine, on the Comstock, is being surveyed and will soon be pushed to completion. This road will also supply the Overman mine, and can with a very little trouble be extended across Gold canyon to the New York and Lady Washington mines.

only he useful for stove-polish and foundry purposes, as it contains too much foreign matter to be good for pencils.

This is exactly what is the matter with all the plumbago we have found on this coast. None of it is pure enough and even the poorest quality is scarcer than most people suppose. Works were established in this city some time since to manufacture crucibles and they have never been able to get enough plumbago to do any work. They get their plumbago from the East and England to make their crucibles and although there has been a great deal of talk about plumbago mines none of the product of any value has come to light. The proprietors of these works stand ready to purchase all that is of proper quality that they can get, but as yet no one has presented himself with any samples worth having.

The *Reno Journal* is informed that Mackey & Fair contemplate building a narrow gauge railroad from Virginia City to Reno.

Short Lectures on Patents.

BY JNO. L. BOONE.

NO. 1.—FOR THE MINING AND SCIENTIFIC PRESS.

To Invent is to Think.

The process of originating a new idea is the same process as that required to plan houses, railroads and all manner of enterprises; the same that accumulates fortunes, and rules nations. Every person who adds to his own fortune or the public growth does so by a system of invention not dissimilar to that required to produce a new mechanical movement, a new combination of devices, or to originate a new mechanical principle.

It has been said that no man invents a complete machine without aid from others; that an invention is an accumulation of ideas from many persons. Necessity compels thought. Circumstances control necessity. One man suggests; another criticizes. Ideas accumulate until some lucky thinker makes the last suggestion that spans the chasm and the invention is complete. The question arises,

Who Made the Invention?

Our patent law says that the first person who produces a complete working embodiment of the invention and applies for a patent therefor is to be considered as the first inventor. In fact it is a race in which the first person who reaches the goal wins the prize. And this is as it should be. No other allotment would be just.

But before the inventor can successfully carry off the prize he must first comply with certain

Legal Requirements.

He must not only invent but he must explain his invention to the public by filing a complete description, drawings and model in the United States Patent Office, so that when the time of his proprietorship expires the public will be in possession of the knowledge he has been the first to give life.

The law says the patent must be applied for within two years from the time that he publicly uses or exhibits his invention, in order

To Obtain a Valid Patent.

This is for the purpose of preventing the public from being deprived of the invention for a longer period than seventeen years (the duration of a patent) from the time it is first shown to the public. Yet it gives the inventor abundant time in which to complete all of his arrangements and secure his patent without unnecessary haste. It is also considered that in the present age, in which every man is a thinker, and therefore an inventor, that others will, independently, invent the same thing in a short time. In other words there is a second man in the race, and it would be unjust to allow the first man to neglect to give the world the benefit of his discovery, and thus deprive other true inventors from doing so. So long as an inventor applies for a patent for his invention within two years from the date of its first exhibition to the public he is entitled to receive a valid patent therefor and so jealous is our law of preserving

The Rights of a "First Inventor"

That it provides for the issue of a second patent to a second applicant if he can prove that he was the first to invent, and that the invention has not been in public use for over two years before his application.

It thus places the two inventors on an equal footing; both hold a patent for the same invention and

The Question of Priority,

Or which is the true and valid patent, must be decided by a suit in the United States Courts, where all patent cases are tried. To provide against the possibility of defrauding the public by the wrongful issue of a patent for an invention not justly patentable, the law provides that before a patent can be enforced by the owner it must first pass through the ordeal of a suit at law in which the defendants can raise the question as to whether the patent is

Valid or Not.

The proof of illegality, however, must be clear and decisive in order to defeat the first patent, as a patent is prima facie evidence that the invention was new at the time the patent was applied for and that the applicant was the first to invent. The second patent would therefore be under a cloud until the first was defeated. The U. S. Courts as a rule require the most positive evidence that the first patent was wrongly issued in order to defeat it.

Interferences Frequently Occur.

If two or more persons apply for a patent for the same invention simultaneously, the Patent Office decides the question of priority. This is done by declaring an interference between the conflicting applications and requiring the applicants to produce proof as to when each first completed a working model or embodied the invention in some practical form. The testimony of the inventor must be well substantiated by reliable witnesses in order to prevent fraud, and as each party is entitled to be present in person or by attorney to cross-question the witnesses of the other parties little chance is left for fraudulent representations in actively contested cases.

Partial Interferences.

Two pending applications may conflict only in part, or one patent may describe without claiming what another asks a patent for. In

either case an interference is declared and the decision of the Office is ruled by the testimony in the case.

It is therefore plain that our law makers have provided ample safeguards for protecting both inventors and the public from being defrauded and with honest officials in the Patent Office and clear headed Judges on the benches of our United States Courts, we can see no ordinary way for wrongs to occur that cannot be readily remedied.

It is those who are most ignorant of the merits of our patent laws that cry loudest against them. We acknowledge that our patent system is faulty in some regards and we shall in some of our subsequent articles try to point out these faults. But as a rule few branches of legal legislation are more thorough in their action and more complete in their protection.

RAYMOND & ELY MINE.—The *Pioche Record* says: The work of putting in place the pumping machinery is now rapidly approaching completion, and it is possible that during the present week the pumps will be in actual operation. All the rods are in place and connected, also all the pumps and bores; the balances of the latter are now being filled. The spur wheels are also nearly ready for work. The pump column lacks only about 250 feet from the surface. In fact, the tedious, laborious and difficult task of constructing and erecting the vast and ponderous appliances for lifting a large stream of water from a depth of 1200 feet, is about to reach what we believe will be a most satisfactory and successful termination. In consequence of the timbering in that part of the hoisting shaft, about 100 feet from the surface, requiring repair, the work in the lower part of the mine was stopped, and probably will not be resumed until this evening or to-morrow. Before the cessation of labor took place the work of extending the 9th and 10th levels was going on. The appearance in the face of the 9th was not looking so well. In a winze which is being sunk from the 8th the prospect is very good. Taking the outlook altogether, the appearance of matters may fairly be characterized as much improved, and leads us to believe that the bonanza period of Pioche is not far off. As regards the ore being raised, only that quantity is brought to the surface that is taken out in making the various explorations by means of the several drifts, winzes, etc. that are being opened. No ore has lately been shipped to the mills, but shipments will probably soon be recommenced.

MINER OF PARK CITY, UTAH.—The *Marsac* mill, of 20-atampa capacity, is to be changed into a concentrator, as the ore of the Flagstaff mine could not be successfully worked by mill process. The Ontario mine is furnishing constant employment for the McHenry mill. The Switzerland mine has struck a well defined lode of superior richness. The Rock Bar mine has a shaft down 100 feet, and a four foot vein of fine ore has been lately struck. The lead is well defined, and has a heavy clay hanging wall and quartzite foot wall. Woodside mine is still being worked, and regular shipments of ore are forwarded to this city. That is a valuable mine. The Highland Mary, Irish-American, Whelan, Green Monster and Porcupine are looking well. The tunnel of the Pioneer is now in about 300 feet, with an excellent showing. —*Salt Lake Tribune.*

SULPHUR.—Extensive beds of sulphur have recently been located in this county by a gentleman named McWorthy, from Oakland, California. The deposits are situated about thirty-five miles west from Mill City, in the Rabbit-Hole Springs county. McWorthy's information relative thereto was derived from an Indian, who, for a trifling remuneration, piloted him to the locality. A quarter section of the deposit has been located, and James McAllister of Mill City informs us that the locator intends to make the limestone useful by converting it into sulphuric acid on the ground if fuel in sufficient quantity can be found on the adjacent mountains. —*Silver State.*

THE TWENTY CENT COIN.—The design of the new twenty cent piece has been selected and approved by Mr. Landerman, director of the mint. The obverse design contains a sitting figure of liberty, with the word "Liberty" inscribed on the shield, the whole surrounded by thirteen stars. Beneath the figure is the date 1875. On the reverse is the figure of an eagle, with the words "Twenty Cent." The edge of the coin will be perfectly smooth, in order to distinguish it from the twenty-five cent coin.

The *Belmont Courier* says: Eight tons of ore from the Barcelona mine (Spanish Belt District), crumbed at the Monitor Belmont Mill, yielded \$3,105 93, or an average of \$404 per ton.

The *Eureka Consolidated* is to have a new furnace constructed at its smelting works. Four furnaces, it is expected, will be run this season by this company.

The *Ukiah Dispatch* says that gold and silver have been discovered near Calpella, and the prospectors have traced the ledge to the Wurtzburg claim.

The general overhauling of the Richmond furnaces compels their shutting down for the balance of this month.

The *Reveille* mine, Tybo district, Nevada, expects to ship, in the next sixty days, \$150,000 in bullion.

Jefferson District, Nevada.

One of the editors of the *Austin Reveille* has been examining the mines of Jefferson district, Nye county, Nevada, and according to the extracts below, taken from his reports, the future prospects of the mines are very flattering for that camp. He says: "The first mine examined was that of the Jefferson silver mining company, comprising 1,200 feet on the southern end of the Prussian lode. An incline has been sunk on the ledge, which dips at an angle of 65 deg., to the depth of 340 ft. At this point a body of water, just sufficient to supply the steam boiler of the hoisting works, has been struck. Along the length of this incline four levels have been started, every one of which we visited carefully. The vein, both in the incline and in the levels, varies in thickness from three to five feet, and is one of the most uniform and best defined we ever saw, the bottom resting on a stratum of decomposed slate of the consistency of putty, whilst the top is incased in porphyry. The first level was started at 65 feet, and is now in 100 feet northerly and 60 feet southerly, the vein being stoped a height of 30 feet on both sides. The second level was started at 140 feet; it is now in 120 feet northerly and 50 feet southerly. Little stoping has been done on either side. The third level was started at 240 feet, and has now reached 85 feet northerly. The fourth level, 340 feet, has been run a short distance northerly. As we said before, the vein maintains its uniform size and dip down to the bottom of the incline and along the whole length of the drift with remarkable uniformity. The Prussian claim comprises 1,000 feet. They have sunk an incline 250 feet deep, at which point they struck a heavy body of water, which cannot be exhausted without greater pumping facilities than the company now possess. Three levels have been started—the first at 65 feet from the surface, running south 75 feet and north 80 feet; the second, 100 feet from the surface, running south 280 feet; and the third, 200 feet from the surface, running south 260 feet and north 100 feet. Both incline and levels are run on the ledge, averaging between three and a half and eight feet in width. Fourteen dollars covers the entire cost of mining and milling one ton of ore. Each of the companies has a ten-stamp mill, crushing wet, and of the latest construction. They work twenty tons of ore every twenty-four hours. Both mills are under the superintendency of Mr. Thomas Mc-Masters."

Important Discovery in Fresno County.

James F. Dodds, John Bye, Thomas Collins and James Lewis have made an important discovery of a vein of gold-bearing quartz on the Fresno river, about three and a half miles below Crook's ranch, and opposite what is known as Indian Peak. The parties mentioned were employed during last summer and fall in constructing the flume of the California Lumber company, and while so employed they found a number of pieces of float quartz, which showed a large amount of free gold. Search was made for the vein, and it was finally discovered on the 19th of last December. They immediately located a claim of 1,500 feet on the ledge, and styled it the Confidence company. The ledge was traced about two miles and shows a width on the surface of about six feet. The droppings all show more or less free gold. They immediately commenced sinking a shaft on the ledge, and as they removed the rock, the glittering particles of gold, peeping from the fragments of quartz, assured them that they had struck a big bonanza. Specimens of the quartz shown us, (and we are assured that they are fair samples of the ore extracted from the mine), were literally bespangled with gold. The quartz is hard and solid, and has a rusty appearance wherever there are any seams. The walls of the ledge are well defined. A shaft 6x8 feet has been sunk on the ledge to the depth of thirty feet, and the vein is found to widen out as it goes down. At the bottom of the shaft the width of the vein is found to be about thirty-five feet. The gold seems pretty generally diffused through the vein, but there is a stratum in the vein which is exceedingly rich. The quartz increases in richness as they sink on the ledge. This fact, coupled with the widening of the ledge, the general diffusion of the gold, the marked definition of the walls of the vein, and its gradual widening out, indicates that the mine is a true fissure, and not a pocket deposit. They have worked about thirteen tons of the ore in an arastra and cleaned up about \$5,000. The first eight tons of ore yielded a little over \$275 per ton; five tons of ore worked since yielded a little over \$515 per ton. They have an abundance of this same class of ore on hand. The parties have been offered, and have refused, \$40,000 for their discovery. The extensions have been located, and the prospects are that other rich mines will be opened. —*Fresno Examiner.*

ALL work on the Dayton mine is suspended for the present, pending the erection of the new pumping and hoisting machinery. The new machinery is a complete pattern of the new machinery of the Caledonia company, and when ready to run will be second to none on the line of the Comstock.

GEORGE M. DANNALS has been elected President of Julian mining district, San Diego county. Mr. Dannals was a member of the legislature from that county last winter, and has been a resident of Julian ever since the mines were first discovered.

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Twelfth Lecture Delivered before the University of California College of Agriculture, on Monday, February 1st, by PROF. C. E. BESSEY.

We take up to-day, first, the myrtles, natural order *Myrtaceae*, a group of tropical and south temperate plants, made up mostly of trees and shrubs, and including about 1,500 species. Most of them are found in Australia, that is, the larger number of species; while in Northern Asia and in North America we find none, so that we have this great group of *Myrtaceae*, without a single natural representative in all North America. The myrtles (Fig. 1), all of them, contain an aromatic oil, which may be considered as the principle which runs through the whole group. It is an important order on account of its timber, its food, its aromatic and its medicinal products.

Under the head of timber, we have standing prominent among the timber trees of the world, the different species of the genus *Eucalyptus*. Of this genus I shall not attempt to say very much, because I find there is no literature on the subject to be obtained here. The trees are all Australian and Tasmanian. As many as thirty or forty species are pretty well known. They are usually trees 100 to 150 feet high, although attaining, in some cases, 300 to 400 feet, and one was measured whose length was 480 feet. It, however, had rather a small diameter; having a diameter of not more than 27 feet, I think; not as large as our large *Sequoias*. They are all interesting, botanically, on account of the peculiarity of their leaves and general appearance. The leaves are broad and regular on the young plants, but they become long and to a certain extent one-sided on the old plants. In the older plants they hang vertically, presenting their edges upward. The species differ very greatly in their value. Some of the species of *Eucalyptus* are exceedingly valuable, others are almost valueless. I will read you what Sir William MacArthur says—and this is in a very rare book. He says, in speaking of these trees: "When fully matured, some of them are not sound at heart, and, even when sound, the wood is very brittle. In several kinds there is a very serious defect, which is called gum vein, the gum or resin passing out through the concentric circles between the layers of wood." It means just this: There is a great tendency to take on wind cracks, so that when you cut a tree you find great cracks between these successive layers, filled with gum. The statement is also made that it is quite apt to split up. I have examined what seem to be the best, taking the Australian authorities. They give them popular names. These popular names cover several species. The most valuable is the *E. sideroploia*, or iron bark. The iron barks are very useful in building railways, putting up buildings and manufacturing implements. Somebody has cited instances where the wood had been used for forty-five years for fence posts, or something like that. It is said to be very durable. It is very strong, and from certain tests made by the British navy, this iron bark was found to be the strongest of almost all the Australian woods; compared with other woods also in England, it was found very strong. While it has all of these qualities, you must remember there is a certain tendency which it inherits with all its common relatives. That is, a tendency to shrinkage. When the boards are put together in a floor, ceiling or anything like that, they are apt to shrink, and so cannot be well used for such purposes. The aptness to have gum-veins and to be hollow at heart when old, also lessens their usefulness. Still, the iron bark you may consider as the best of all, and I should say that these are

The Ones that ought to be Imported.

E. leucocorylon, *E. crebra*, *E. paniculata* and *E. bicolor* are all close allies of *E. sideroploia*, and are popularly called iron barks. Australian gums are largely imported now; why not import these, and especially the first one, rather than those that are brought in? The second best among the species of *Eucalyptus* are what are popularly called the blue gums. We have here what is called blue gum, *Eucalyptus globulus*. *E. terminalis*, *E. hamata*, *E. botryoides* are all blue gums. They are highly prized in Australia, and are used for ship-building and also very largely in wheelwright's work for manufacturing wheels and all other parts of wagons. The *Eucalyptus* are said to possess medicinal virtues.

An allied genus, *Syncarpa laurifolia*, found also in some provinces of Australia, and called there the tridentine tree, is said to be exceedingly valuable for use as piles. You know that in some places an ordinary pile driven into the mud will be used up in five to seven years, depending upon the number of teredos which attack the piles. This *Syncarpa* is said to be teredo-proof; and if you see proper to get evidence of this, go over to the Academy of Sciences, and you will find a specimen pile there that was a long time in the water, driven where teredos abound, and there is no teredo mark on

Continued on Page 270.

MECHANICAL PROGRESS.

Is Wrought Iron Fibrous?

In the adjourned discussion upon Mr. Hutchinson's paper "On Reversing Rolling Mills," by the members of the Cleveland Institution of Engineers, which was published in the last number of *Iron*, p. 361, Mr. Jeremiah Head, a gentleman well versant in the art of rolling plates, questioned the fact of there being really fiber in the plate at all. He said: "I am inclined to think that the term fibrous, when applied to the structure of wrought iron, is really inappropriate and misleading. A truly fibrous material, such as wood, resembles wrought iron only in the appearance of the fracture. But the fibers of the wood are not at all ductile, and therefore its appearance when fractured arises from the broken fibers of which it is built up becoming apparent. But the similar appearance of a fractured piece of wrought iron arises from the ductility of the molecules of iron, the apparent fibers having been made for the first time in the act of bending. If we could see the iron before bending, we should probably find it quite innocent of any fibers, however ductile the quality."

That the fibrous appearance of iron is only disclosed after the bending of the iron, and is really produced by the tenacity and ductility of the molecules of iron is very plausible, and rather novel in conception, but goes dead against all the general notions of those most intimately acquainted with iron in its rolled state. The general notion is that iron not only seems to be, but really is, fibrous; that it is just a bundle of more or less parallel wires, more or less welded together. If a bar of rolled iron be soaked in a weak solution of nitric acid, its fibrous structure will be apparent to the eye, so that, to quote Mr. Head's own words, "we can actually see into the iron before bending," and "find it quite innocent" of the charge he brings against it of not being fibrous. There is not the least doubt about there being actually what we, comparatively speaking, call "fiber" in iron. Yet Mr. Head's idea is eminently suggestive. We know, by bitter experience, that the fibrous structure of axes, etc., seems to be gradually changed into a crystalline state by the force of vibration. We also know that boiler plate, from the continued application of heat, seems to lose its fibrous character and become crystalline.

The president in his opening address alluded to the fact thus: "From some tests I have lately been making of the iron cut from the plates of two boilers which had ripped at the seam, I found that the flame playing at the convex bottom of the boiler had affected the iron at the seam, so as to make it cold-short, of small tensile power, and apparently crystalline in its fracture. On annealing the pieces of iron cut from the seams it was found that the cold-shortness had disappeared, and that the tests both for tensile power and ductility had been restored to their original condition." It is probable that the crystallization is only in appearance—that, in point of fact, the elongated welded crystals or molecules which constitute the fibers have merely lost the strength of their tenacity and ductility—have, in fact, become brittle and not been able, in consequence, to stand the same amount of fatigue. This theory, if correct, fully accounts for the fact which seems so puzzling to explain—that by proper toning treatment the so-called crystalline iron can have its fibrous nature restored so as even to stand its original tensile strain.

A NEW SYSTEM OF DREDGING.—M. Bazin, of Angiers, France, proposes to attach to a steamer with an engine of 60-horse power two pipes on each side at some twelve feet below the water line. These pipes are to be ten inches in diameter, about fifty feet in length, and are to be connected to the ship, so as to swing up or down, and also so as readily to yield to the movements of rolling, etc. The extremities of the couple on each side are united by tubes of like diameter, open at the forward end. In clearing out a quicksand, the vessel is got under way at the speed of eight knots per hour; and on reaching the obstruction the tubes are lowered with the soft mass. The water pressure above the sand or mud, which of itself would force the material into and up the tubes, is aided by the outward motion of the vessel, and the result is that the mud is driven through the tubes and into the hold. When the vessel is full, the apparatus is raised, and her contents hoisted out or otherwise discharged in some suitable locality. M. Bazin says that, with tubes of the size and with the speed above mentioned, 43,200 cubic feet of mud per hour could be raised. He points out that, in case of their becoming obstructed, the tubes can easily be cleared by simply elevating them out of the mass and allowing the water to rush through them.

CAR STARTER.—An improved "starter" for horse cars was recently tried in Baltimore. The invention consists simply of a grooved iron cam that is attached on each side of the axle near the wheel. This cam extends above the axle and affords a leverage of twelve inches. Through the grooves on the top of the cams run two wire ropes that are attached to the gooseneck and double-trees. The cams, by means of a heavy spring, resume their upright position whenever the car stops, and the leverage they offer in starting lessens the work of the horses.

THE EFFECT OF COLD ON IRON.—As a general rule the cohesive force in bodies increases as the atoms or molecules of which the bodies are composed are brought into closer proximity to each other and heat tends to separate the particles of matter, and thus to weaken the cohesion existing between them. In accordance with this well established law, a lump of ice, in which there is a certain amount of tenacity, loses nearly the whole of this force when it has been converted into water by the agency of heat; and when, by further heating, the water has been converted into steam, the cohesive force is entirely overcome by elasticity operating in the opposite direction. A great number of experiments have been made for the purpose of determining the influence of variations of temperature and other circumstances on the tenacity of the metals within the range of their solid condition. In 1844, Wertheim published an elaborate paper relating to this subject in the "Annales de Chimie et de Physique," in which he shows that, although in most instances the metals increase in tenacity as the temperature decreases, it is not strictly so in the case of iron, the tenacity of which increases with increase of temperature up to 212 deg. Fahr., but beyond that point it follows the general law.

MAGNETIZATION.—M. J. Jamin's researches point to an important modification in the construction of magnets. Suppose that a great number of plates, which, after being separately magnetized to saturation, are placed together. The magnetism of the combination will be seen to increase up to a limit which cannot be passed, and which is reached when the polar surfaces are filled. Suppose that ten plates are required. If now we recommence the same experiment, applying the same plates against two iron armatures of a large surface, the intensities will increase much more slowly, because the sum of the magnetism is diffused over a more considerable extent, and the limit will not be reached till this extent is full. For this it may be needful to superpose twenty, thirty or forty plates, and, generally speaking, a number so much the greater as the armatures are larger. The total power of the magnet will, therefore, increase with its armatures.

WELTING.—In welding iron, as is well known, the pieces are heated to whiteness. When iron is to be welded to iron this plan answers well enough, but if iron is to be welded to steel the white heat often destroys the steel completely. To remedy this evil a patent has recently been taken out, which promises to remove all difficulties. By this process the surface of the metal to be welded is moistened with water, and on the wet surface there is sprinkled a compound consisting of 1 lb pulverized calcined borax, 1 lb. fine iron filings, and 4 oz. pulverized prussiate of potash, intimately mixed. The two surfaces are then wired, or otherwise held together, and raised to a red heat, or about 600° to 700° Fahr. When subsequently subjected to rolling or hammering the joint is completed, while the steel is not sufficiently raised in temperature to be at all injured by the operation.

WHAT IS STEEL.—A correspondent writes to the *Scientific American* as follows: I contend that no steel can be made without carbon. My friend claims that chrome steel, by the introduction of chrome ore into the crucible with ordinary iron, secures the different grades in proportion to the amount of chrome used. I claim further that the result of such a process is not steel, but an alloy or chromate of iron. Which is right? That journal answers as thus: It may be steel, because the iron itself contains carbon, the presence of which is, as you say, essential to the formation of steel. The chromium enters, like manganese and other metals, as an alloy, and modifies the properties of the steel.

NEW PROCESS OF ENGRAVING ON COPPER.—The hydrographic office at Paris has begun a new process of engraving on copper which promises, by its rapidity and the moderation of its price to be very widely useful. It consists in substance, first, in covering a plate of copper with a thin shell of adhering silver, upon which is spread a thin layer of colored varnish; second, in drawing thereon, with a dry point, the lines of topography, and lettering, precisely as one engraves with a diamond upon stone; third, in corroding the traced parts by means of the perchloride of iron.

AN IMPROVED WOODEN BARREL.—H. W. Fitzhugh, of Bay City, Mich., has invented a new device in barrel manufacture, which consists in using straight staves having parallel edges, with constricted bands, whose overlapping ends are fastened by a screw extending into the wood. This enables the barrel to be made entirely by machinery, and renders cooping unnecessary.

A NOVEL BRIDGE.—Between the towns of St. Servan and St. Malo, at the mouth of the River Rhone, France, there is a novel bridge. It is a platform supported on wheels which run on rails at the bottom of the estuary. At high tide the wheels are beneath the surface of the water. The top of the platform is level with the quay on each side, so that it is easy of access for both men and horses.

HIGH AND LOW PRESSURE.—Somebody asks, What is the difference between a high pressure and a low pressure engine? A. In one the steam is condensed, in the other it is exhausted into the atmosphere.

GIFFARD'S RAILWAY CAR.—M. Henri Giffard, inventor of the Giffard injector, has succeeded in constructing a railway car, the body of which is so supported on springs that all oscillation and jarring is entirely obviated, and the passengers within are enabled to read, write, and otherwise employ themselves with as much facility as if not in motion. These cars are now in use on the railway between Paris and Lille, France. The platform is supported on heavy springs of its own, and carries at each extremity standards, which, in turn, are surmounted by ponderous leaf springs, to the ends of which the body of the car is suspended. It was found, on a first trial, that the peculiar horizontal oscillation which is so very fatiguing to the traveler was entirely suppressed, and that a light, vortical, elastic movement which remained was easily obviated by adjusting the suspending rods. The weight of the car is somewhat more than that of those ordinarily employed on European railroads, and its cost is higher.

SCIENTIFIC PROGRESS.

Science in the Utilization of Waste.

In no way, perhaps, has science been of greater benefit to the commercial world than in what it has taught us in the way of utilizing the waste products of manufacture. The immensely valuable and now almost indispensable series of dyes which science has of late taught us to eliminate from the hitherto useless waste of gas manufacture is too well known to need more than a mere reference in this connection. Numerous other similar instances might be enumerated; but our present purpose is to call the attention of the reader for a moment to the almost inestimable boon which it has secured to mankind in bringing to his knowledge the organic compound known as Glycerine.

The deprivation of which would now be found a most serious detriment to the world. This sweet principle of oil, which is now largely obtained from the waste of the soap boiler, was first discovered by Scheele, in 1783, and its true nature ascertained by Chevreul, in 1819. From that time until within a very few years it merely held a well defined place as a simple fact in organic chemistry. But the new impulse given to scientific investigation within the past two decades has led a great number of investigating minds to examine and study into the nature and possibilities of this new organic compound. The first inquiries were directed to its more thorough purification, and no sooner was it presented to the world abundantly in its pure form than its use became extended day by day. The principal features connected with the improvement in its manufacture relate to its distillation, and still later to its purification by crystallization by Sarg, and in 1871 he purified in this way twenty-five tons. As for its application, it is now more varied than that of any other substance springing from the chemical arts. It is used in wine-making, beer-making, confectionery, liquors, in cloth-making, in calico-making, in preparing leather so as to remain supple and durable, in the tobacco factory, for lubricating machines and fire-arms, etc., preserving organic matter, filling gas meters to prevent the effect of cold, for making rollers for printing presses, in the art of perfumery, in medicines, etc.

Nitro-Glycerine.

But of all the applications of glycerine, the most curious and important one is that of making an explosive compound for blasting. In 1847 an Italian chemist named Sobrero, working in the laboratory of Pelouze, discovered that the action of concentrated nitric acid or a mixture of nitric and sulphuric acid upon glycerine produced a peculiar oily liquid, having among other properties that of exploding when struck by a hard body, or when heated. At first it was only regarded as one of the many curious compounds that are born every day in the chemical laboratory. Any practical application was not thought of, for the glycerine then was too expensive a substance to enter into competition with other substances used in making explosive compounds. It was reserved for a Swedish chemist named Nobel to make an application of this oily compound called nitro-glycerine, and by improvement in the process of its manufacture, and the consequent impulse it gave to the separation and purification of glycerine, it is now a substance of every-day use by those engaged in mining and in large engineering works requiring the removal of large bodies of rock; and, notwithstanding it is an extremely dangerous substance to handle, and many lives and much property have been destroyed by it, contractors on large works say that they prefer using it to gunpowder, with all its attendant risks.

Dynamite or Giant Powder.

So important and advantageous has its use become as an explosive compound, that in spite of its acknowledged danger, men would use it in many cases in preference to other and safer explosives. And here again science came once more to the relief of mankind and led the way to a preservation of this hitherto dangerous compound in a form almost perfectly harmless, and, in fact, absolutely harmless as an explosive, save when placed in contact with some other explosive, a combination which is practically unnecessary until at almost the very moment when it is desired that its terrible energies should be brought into active play. This is the form which nitro-glycerine is made to assume when presented to the world in the form of dynamite or giant powder.

A NEW PAPER BOARD.—The multiplicity of uses to which paper is being applied is constantly leading to new devices for rendering it more suitable for these applications. The latest advance in this direction is given as follows: A new method of manufacturing paper board, to make that article more generally useful and durable, is described as follows: When a sheet of paper is immersed in an ammoniacal solution of copper, and then dried, it is said to be quite impregnable to water, and does not lose this quality even though the water be boiling. Two sheets of paper thus prepared, and passed through a cylinder, adhere to each other so completely as to be quite inseparable. If a large number of sheets so prepared be cylindered together, boards of great thickness are obtained, the resistance and cohesion of which may be increased by interposing fibrous matters or cloths. The substance so prepared is quite as hard as the closest grained wood of the same thickness. The ammoniacal solution of copper is prepared by treating plates of copper with ammonia of the density of 0.880 in contact with the atmosphere.

NEW MATERIAL FOR DYE-STUFFS.—It is claimed that, according to a method patented by Croissant and Bretonner, many kinds of refuse organic matter, as sawdust, decayed wood, horn, bran, starch, moss, etc., can be converted into valuable material for dyeing. The process rests upon the dehydrogenation of the substances by sulphur at high temperatures, and seems very simple in practice. Thus bran, for example, is simply mixed to a uniform paste, with the proper quantity of caustic soda and flowers of sulphur in an iron vessel, which is then covered and heated in a furnace to 482 degrees to 572 degrees. A portion of the sulphur is taken up by the organic matter, and much sulphuretted hydrogen is given off, and at the close of the operation a friable hygroscopic mass remains which is completely soluble in water of a deep green color, and exhibiting an extraordinary affinity for organic fibers, so that they can be dyed with it without a mordant. The dyes formed, even from the same substance, may be varied in shade by altering the treatment; and some materials require a much higher temperature than others for their transformation.

TEMPERATURE OF THE SUN.—In opposition to the now prevailing theory among astronomers and physicists that the sun possesses an exceedingly high temperature, M. Violle has maintained for some time that this temperature is only about 3,000 degrees. In a recent publication he gives the result of some further researches upon this subject, in which he attempts to establish the solar temperature to be the temperature which must be possessed by a body of the same apparent diameter as the sun, in order that, endowed with an emissive power equal to the mean emissive power of the solar surface, it may emit in the same time the same quantity of heat as the sun. He assumes finally that the mean emissive power of the sun is only equal to that of melted steel.

CURRENTS IN JUPITER'S ATMOSPHERE.—Not content with studying the laws which govern the winds or atmospheric currents on our own planet, Knobel has given a series of drawings of Jupiter's surface, as observed night after night by a powerful telescope, while Dr. Lohze, of the observatory at Bothkamp, is making another similar series. When these are compared and discussed with all other known drawings, it is hoped they will reveal the laws of the winds or atmospheric currents which prevail on Jupiter and produce the rapid changes observed on its surface.

A SIMPLE WAY TO FIND THE MERIDIAN.—Mr. Geo. W. Blunt, the well-known nautical expert of New York city, gives the following simple mode for running a meridian line: Take a piece of board, or any similar material, and describe on it a number of concentric circles. Place this in the sun; over the center hang a plummet. Observe the shortest shadow from the plummet; the sun will then be on the meridian; draw a line to the center of the circle, and that will be the true meridian line. This will do to mark the apparent time or to correct the compass for variation.

MAGNETIZING THE SPECTRUM.—Choquet has communicated to the French Academy the observation that the magnet exercises a peculiar influence upon the spectra of various substances. The spectra of sulphur and selenium become very pale and finally disappear, while the spectra of bromine and chlorine become more intense by the influence of the magnet.

WHY DOES A STAR SCINTILLATE?—Because of the interposed changing layers of air of different densities. The diverging rays are caused partly by the irregular figure of the crystalline lens of the eye, and are partly owing to the pull of the six muscles which move it.

MINING SUMMARY.

THE following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

CALAVERAS.

MINING.—Calaveras Chronicle, April 17: We have nothing startling to record in the way of mining in this vicinity this week, but there is no "letting up" with regard to the briskness with which operations are being pushed. The hydraulics are all in full blast and the tunnel-claims are running full handed. Water is abundant and miners are rushing things while they have a chance. Work will be commenced in Prindle & Duryea's new hydraulic, on Tunnel ridge, reference to which has been previously made in this paper, in a few days. We learn that the laying of the pipe necessary to convey the water to the mine is nearly completed. There doubtless are many places on the ridge, yet unoccupied, that will pay well for working, and the success of the claims now in operation will have a tendency to stimulate prospecting. Tunnel ridge will yet be all washed into Chili gulch.

QUARTZ DISCOVERIES.—We learn that some very rich discoveries in quartz have lately been made in Mosquito gulch. Two leads have been found right in the town that prospect very rich and have every indication of being permanent ledge. The work done upon them has resulted most encouragingly and operations are being pushed forward with vigor. There is no more promising quartz mining district in the county than Mosquito.

CONTRA COSTA.

COAL.—Contra Costa Gazette, April 17: Among the many discovered indications of coal deposits in the county that may yet prove of practical value are those at the head of the Tassajara creek, where lately some prospect was made of a vein on the property of Mr. John Johnson. This vein was prospected to the depth of about 20 feet down from the outcrop, and yields coal of very fair quality; but, as we learn from Mr. Thomas Johnson, son of the proprietor, the vein, which was first increased in width with the depth gained, narrowed with the last eight or ten feet, as though it might soon pinch out; and it is not their intention to work it further at present. Near by, on another tributary of the Tassajara, as Mr. Johnson informed us, Mr. Sangmaster has the indications of a large, fine coal vein, but is not taking any measures for developing it, though he has tested it far enough to feel pretty well assured that it is a vein of much value. There would seem to be no reason why the district south and adjacent to Mt. Diablo should not have the same coal measures as found on the north side, though the angle of the stratification left by the uprising of the mountain are greater, and the measures are probably more broken up.

EL DORADO.

MINING ITEMS.—Mountain Democrat, April 17: Our Greenwood correspondent, "Prospector," has been rambling around among certain mines on the north side of the county, and sends the following items: The Sliger mine and mill have been running for the last two weeks, and judging from the plates outside the battery, this will keep up its high reputation as a "paying institution."

At the Cederberg they are still sinking, but since their Warring drill became disabled they have not made the progress they would under more favorable circumstances. The mine is looking first rate.

The Spanish claim is looking well, with a good prospect of a profitable clean up.

The French claim, under the management of Mr. Desmarchats, one of the original owners, is paying remarkably well.

The Five Cent Hill company made a good showing the last month, having paid a good margin above expenses. This mine is under the able management of Mr. Cornwall.

The International, W. A. Jones, superintendent, bids fair to establish its reputation as one of the best mines in our county, having a ledge 20 feet wide, which contains some of the richest sulphureted ore, according to assay, in the State. The superintendent informs me that he intends to ship several tons of the ore to San Francisco, to be tested by working process, and if it works within 20 per cent. of assay, the company will erect reduction works on the mine.

The Taylor mine is proving a success under the management of Walter Schmidt. The ten-stamp mill never stops unless something breaks, which is not often. The mine will supply 20-stamps, and I think the company is making a great mistake in not having that number set up.

The Rosekranz mine, being the first southern extension of the Taylor, has commenced operations, under the management of N. D. Burlingham, and from the present prospects will rival the Taylor.

The Garden Valley mine, also under the management of Mr. Burlingham, has reached a depth of 80 feet, the ledge being well defined and prospecting "way up," as the miners express it.

The Mansfield mine is looking well, I have been informed, and there is a rumor afloat that this mine has been sold to an English company.

INYO.

ROSE SPRINGS DISTRICT.—Panamint News, April 13: A short time ago a party consisting

of E. A. Culver, Prof. Chas. G. Meyer and P. A. Craigie, made a visit to Rose springs district, some twenty miles north from this camp, in the Panamint range. Following are the assays obtained by Prof. Meyer from ore selected by the party, from eight different ledges, and we doubt if a better showing has ever been made by any district on the Pacific coast: Star of the West, No. 1, \$845.13; Lanzi, \$889.11; Polar Star, \$1,405.33; Maria, \$216.77; Star of the West, No. 2, \$1,099.61; Garibaldi, \$348.73; North Star, 1,363.23; Star of the West, No. 3, \$1,189.13. Total, \$7,357.04. Average per ton, \$919.63. The above assays for the Garibaldi are not up to the usual average of those heretofore made. The ore from that mine has generally assayed from \$628 to \$1,600 per ton. Assays have also been had from the North Star as high as \$1,700. The certificate of the assays by Prof. Meyer had attached thereto (by ceiling wax) the "buttons," and this we believe has been sent down to parties at San Francisco. If any other of a like number of claims in one district can beat this showing, we should like very much to hear of it.

OUR ORES.—For a long time we have been satisfied that our mines were producing a better class of ore than many gave them credit for. The concentrators, which have been pretty thoroughly tested, have demonstrated this fact. Instead of finding so large a percent of copper and other mineral denominated "base," it is shown that there is a much greater amount of chlorides than was supposed in those ores which were not put down in the list of free milling, and they are of so high grade that it is believed that a resort to roasting and finally making the silver bullion right here will prove more profitable than shipping the concentrations to Swansea. In the absence of chlorides concentration does well enough, perhaps, but there is so little specific gravity as between the chlorides and gangue, it is almost impossible to save the chlorides, the richest part of the ore. By preparing the ore in a roasting furnace the chlorides are saved by amalgamation, and where there is so little percent of copper and other base metals, it will be found more profitable to destroy them entirely. We have some ores carrying very little chlorides and with these the concentrating process may be adopted. At any rate we are very glad the company have determined upon the introduction of the Stetefeldt, as the shipments or bullion will advertise our mines to a degree beyond anything else that can be devised.

DARWIN DISTRICT ITEMS.—Inyo Independent, April 17: The latest mining news from Darwin is of the most encouraging character. We are assured by two or three friends that so far as they know, not a mine upon which work is being done (and there are a large number), but is developing splendidly. The Capital, belonging to the Brown Brothers, Baxter, Bell and White, has turned out to be a magnificent mine. This is a tremendous ledge. With respect to the Defiance and Grand, cutting across between the two, and easily traceable from the summit of the hill many hundred feet in either direction. The main shaft is down 85 ft, and the others at different points 10 ft each, and every one in splendid ore, running as high as \$600 per ton. Drifts from the bottom of the main shaft show a deposit of this kind of ore not less than 30 feet in width. The developments in the New York are exceedingly flattering. Some Mexicans are erecting a small furnace on a mine near the Promontorio and will soon have it in operation. The Christmas Gift furnace men and machinery, we believe, are expected at Darwin now in a few days.

NEVADA.

KENTUCKY.—Foothill Tidings, April 17: Kentucky is getting to be the favorite stock for investment among those best posted on Grass Valley mines. The location of the mine, closely contiguous to the Idaho and Eureka, and the now patent fact that the works will soon be started and the shaft be put down to the 400-ft level without delay, leads miners and others here whose memories run back to the time when Idaho stock could have been bought for from \$5 to \$20 a share—only a few months before the big strike which sent it up to \$250—to desire a few shares, and we hear of sales recently made at from four to five times the price of the same stock two months ago.

PLACER.

NICK FINN.—Placer Herald, April 17: All the big chunks of gold are not found yet. Only a few days ago Ben Hawkins, of Ophir, picked up a nugget in a ravine below the old St. Patrick mine, that weighed three ounces and three-quarters of a pennyweight, or \$48.60 at \$16 per ounce. It is true these large chunks of the root of evil are not lying around on the surface as thick as they were twenty five years ago, but evidently there are enough left yet to warrant a person in keeping his eyes open. Next.

PLUMAS.

THE BIG CHUNK.—Plumas National, April 17: We heard a story, the other day, which gives a color of truth to the report of the finding of the two pieces of gold at French Ravine, but the first story is not altogether right. It seems that an old Frenchman who goes by the name of Henry found a piece of quartz and gold at the mouth of French Ravine. He kept still about it, only showing it to one or two, and one of the men who saw it gave it as his opinion that it was worth eight or ten thousand dollars. Several very large pieces have been found in French Ravine, and it is quite probable that this story is true.

GREENVILLE MINING NOTES.—Bachelor shipped \$3,000 for sixteen days' run of the

Kettle mill—twelve stamps. His ledge is over 20 ft wide and improving in richness as the workmen go down. Henry O'Toole is working a full crew of men, and his ledge is turning out first-rate rock. Tanner & Wiles are crushing rock from the old Correlles ledge, which is paying splendidly. The Green Mountain is making good its usual reputation for being one of the best paying mines in the county. The Union company has commenced drifting, with a first-rate prospect. The Baker mine is being worked by a full crew, and is yielding some good rock. The Indian Valley mine is full of men, who are driving ahead briskly under the new administration of Whitlock & Hall. The Greenville mines are decidedly "on the come up," and a brisk season is looked for.

SAN DIEGO.

JAMUL RANCH MINES.—San Diego World, April 17: On the Jamul ranch, a short distance from San Diego, Henry Burton discovered a lead of galena-bearing quartz, which assays \$24 per ton; that the ore of the Jamul mine assays \$44, in gold and silver, per ton; and another ledge has given assays of \$59.85, in silver and gold, per ton. All these mines are on the Jamul ranch, but in different localities. The owner of the ranch is confident of the richness of these ledges, and is anxious to have a company of reliable men take hold of them for the purpose of development, and is willing to give the most favorable terms.

SAN BENITO.

SAN BENITO MINES.—Hollister Enterprise, April 10: This is the name of the quicksilver mines on the headwaters of the San Benito, owned by Messrs. Cody, Tully and others. The mines have been prospected to the amount of several thousand dollars, with the most satisfactory results. Some two years since these mines were sold conditionally to an English company, but after long delays, and failing to meet their obligations, they reverted back to the parties now in possession, who commenced their immediate development. A furnace has been erected, tunnels run, shafts sunk, and everything about the premises indicate business of the most encouraging nature. An abundance of ore of the finest quality being taken out, and we are assured that in a very short time they will be shipping via Hollister to San Francisco, large quantities of bottled quicksilver. Other rich discoveries of cinabar have been made in that locality recently—Sheriff Ross and others being the fortunate locators. It is safe to predict that ere long San Benito will rank the foremost county in the State for the production of quicksilver.

SIERRA.

LOCATIONS.—Mountain Messenger, April 17: The Oro G. M. company has located the waters of the South Fork of the Yuba for mining purposes; head-dam to be between the County Hospital and S. Wood's residence.

J. A. Kluemper, et al, have located 600 feet of mining ground at Fir Cap, commencing on the line of the Fir Cap company's claims.

H. Desrosiers, et al, for the Iowa M. company, have located all the water that flows from their drain tunnel, for mining purposes.

E. Stone, et al, have located a lot of mining ground near Galloway ranch, 2,798x933 feet.

G. W. Perkins, et al, have located the mining ground formerly known as the Dutch mining claims, at Forest City.

Lightfoot company, —James Dunphy, et al, have located ten claims of 100 feet each in Hardscrabble mining district, commencing at the S E corner of Summit company.

Enterprise company, —S. M. Boyce, et al, have located ten claims of 100 feet each in Fair Play mining district, commencing at McMurray & Co.'s N E line.

Honest Miner company, —E. A. Parlin, et al, have located ten claims of 100 feet each, fronting on Fair Play Ravine, adjoining Boyce Bros' claim.

Summit company, —W. E. Atkinson, et al, have located nine claims of 100 feet each, in Hardscrabble mining district, beginning at the N E corner of Last Chance claim.

Owen Owens, et al, have located 3,750 feet of a ravine between Centerville and Topphackin Flat, to be known as the Swansea Ravine, for a tailing claim.

D. H. Cowden, et al, have located the bed of the South Fork of the Yuba for mining purposes, commencing at a point immediately South of Seitz's house and running down the river to a point where M. Mead's water pipe crosses the stream.

Lewis Hill, —Jack Wolf, et al, have located a mining claim 800x3812 feet on the ridge west of Eureka.

Summit company, —W. B. Rnsell, et al, have located a mining claim on the flat between Howland Flat and Cold Canon. The ground was supposed to belong to T. McFarland, et al, they having bought it at Sheriff's sale, but the recent locators claim that it was subject to relocation.

SOLD OUT.—Mr. Williams has sold his interest in the Exchange mining claim, located at Monte Cristo, to P. Thatcher, rumor says for \$6,000. This claim has been paying steadily from ten to fifteen dollars per day to the hand for a long time. This ground was supposed to be worked out twenty years ago and abandoned, we believe. The new company went back into the hill where the wisecrack said there was nothing but bedrock, and found a very rich blue gravel lead. Three other companies are running for the same channel, one being composed of John Zimmerman, David Kime and others, another of F. Eschbacher, Tom Pritchard, et al, and the other is the Swallow company. The first has been taking pay for

several weeks, but the others are not yet in. If prospects indicate anything, Monte Cristo will be a lively camp in a year from now. On the Excelsior side Jim. Patterson is pushing his tunnel ahead to strike the same lead, which he will undoubtedly do. The ridge under which this channel lies is heavily capped with what miners call lava, and the theory which prevails with many, that this lava came up from the interior of the earth immediately under where it now lies, has had a tendency to prevent prospecting. It is now getting to be pretty well known that where you find a ridge capped with lava and cement, a channel may reasonably be looked for under it.

TRINITY.

HOW THE MINES PAY.—Trinity Journal, April 17: We have always held that the gravel deposit of Trinity county are not excelled in richness by those of any other section. Two causes have operated toward placing the product of our mines below, we may say far below, what it would be under more favorable circumstances. The first of these causes, and the easier removed, has been the absence, in years past, of improved mining machinery, appurtenances for the removal of gravel at a low cost and apparatuses for the saving of a larger percentage of the gold contained in that gravel. This drawback has been removed in a great measure, during the past few years, by the introduction of larger iron pipe, Little Giant and other improved nozzles, undercurrents and a more liberal use of quicksilver. In fact our mines are now in excellent condition, and were it not for the extreme scarcity of water would this year have made a noble showing. But scarcity of water is what's the matter; under existing circumstances we are at the mercy of the seasons and the past season has been unmerciful. Our miners are idle; our improved machinery and gold-saving appliances lie unused; our hidden treasures remain buried beneath immense banks of gravel. But that these treasures exist is proven by even the small amount of work done this season. The Weaverville Ditch and Hydraulic mining company, with only sixteen days water, have taken out \$3,100 in the Ward mine on the Oregon Gulch mountain. Trotter & Smiley, at Douglas City, have cleaned up \$4,000 for eighteen days run. These tangible results show that our mines pay handsomely. But even at this rate, two or three week's work during an entire season will scarcely justify the fitting up of new claims. What we require is water, more water, and above all certain water. The caprice of a season is no longer to be depended upon. Ditches must be constructed from our larger water courses to the mines. When such enterprises are entered upon and completed the prosperity of the county will be secure.

TUOLUMNE.

ARASTRAVILLE MINING ITEMS.—Tuolumne Independent, April 10: Frank Prudhomme has found a vein of quartz at Mt. Salter, on this side of the Tuolumne, towards Summerville. Our informant says "it prospects awfully!"

Mr. Easton has enlarged his tunnel and intends putting on a whim for the purpose of sinking.

H. B. Fowlee and Sam. Smith have just started in on their "new find." This vein is about 500 ft from the Hill & Wilson, and running nearly parallel.

G. C. Grey & Co. are opening a good vein half a mile east of Arasterville. They have ran a drift in on the vein and have taken out twelve tons of rock, which, after being run through an arastra, yielded eleven and a half ounces of gold—nearly an ounce to the ton. They are going to sink a shaft in the tunnel, on the chute, which improves as it goes down. Specimens of this rock before us is grayish red, mixed with sulphurets and showing free gold plentifully.

Some Italians, who have been working in a gulch, a short distance from Frank Prudhomme's cabin, washed up last week about twenty ounces of the prettiest kind of gold. From all accounts this is a favorable section for prospectors.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—Gold Hill News, April 15: Daily yield, 450 tons of ore. The ore stops on the 1500-ft are all looking well and yielding the usual amount of rich ore, as are also the stops on the 1400 and 1300-ft levels. The C & C shaft is sunk to a depth of 366 feet, the bottom in good working ground. A new and powerful double cylinder donkey engine is on the ground ready to take the place of the smaller one now in use. The old engine will be used to hoist the dirt from the deep pits that are being excavated for the reception of the huge stone foundations for the hoisting and pumping machinery. The pit for the foundation of the pumping engine is 16 feet in width by 67 feet in length, and will be 27 feet in depth.

CALIFORNIA.—Cross-cut No. 2 on the 1500-ft level is in a distance of 273 feet, the face in low grade ore. Cross-cut No. 3 is in a distance of 251 feet, the face still in rich ore. Cross-cut No. 4 is in 132 feet, the face in low grade ore. Cross-cut No. 5 is in a distance of 54 feet, the face in fine ore. The north drift in the ore vein is still being rapidly driven ahead to connect with the cross-cut No. 4, the face of the drift still in rich ore. The main north drift, or enlarged air gallery, on this level is being steadily pushed toward the Ophir line. No work is being done on the 1550-ft level at present. The joint east drift on the 1400-ft level is being continued across the

eastern portion of the ore vein. This winze on this level being sunk to connect with the 1500-ft level is down 55 feet, the bottom still in ore of a fair quality. The south drift from cross-cut No. 3 to connect with cross-cut No. 2 on the 1400-level has advanced 18 feet during the week, this fact in ore of a fair quality. The joint east drift on this 1300-ft level has been advanced at this rate of $3\frac{1}{2}$ ft per day during the week, the face still in clay quartz and porphyry mixed.

OPHIR.—There is little or no change whatever in the looks of the ore breasts, the daily yield, or the quantity of the ore produced. The north cross-cut at the bottom of the north winze on the 1600-ft level is now in a distance of 130 ft, the face still in fine ore. Five east cross-cuts have been started on this 1700 ft level. The first of these cross-cuts is nearly on the line of the Ophir and California; the second 100 feet further north, and each succeeding cross-cut 100 feet north of the other. These cross-cuts have been pushed out a distance of 40 ft each, and when everything is in complete readiness, it is the intention to drive them all ahead at once, thus cross-cutting the entire ore vein on that level at one and the same time, and prospect it in the most thorough manner possible.

CALEDONIA.—The new shaft is now down 85 ft. The excavation of the pits for the reception of the foundations for the new machinery is making rapid progress, as is also the erection of the double cylinder donkey engine to be used for sinking the shaft until the erection of the other engines is completed. Sinking the incline at the old works is making good progress. Several car loads of the new machinery arrived during the week, and the remainder is expected daily, until the whole is on the ground.

BELCHER.—Sinking the main incline is making steady progress. The south winze is now down to the 1500-ft level, and a drift has been started south to connect with the main north drift from the incline. The bottom of the south, middle and north winzes are all in fair ore. The face of the south drift on the 1500-ft level is still in quartz and porphyry, mixed with clay and small streaks of ore. The timbering of the new air shaft below the 800-ft level is rapidly approaching completion. Daily yield 450 tons, keeping the mills all steadily running.

JULIA.—Sinking the main shaft is progressing $2\frac{1}{2}$ ft per day. The new air compressor is in place ready to start into full operation. The Burleigh drift for the shaft will also be in readiness for operation in a day or two more. The shaft is now down 1266 ft, or 266 ft below the 1000-ft level.

SAVAGE.—The water tanks at the 2200-ft station are about completed. Enlarging the main drifts, retimbering, and the laying of the car tracks on the 2200-ft level is rapidly approaching completion. Driving the north drift on the 2200-ft level is making the usual good headway.

CHOLLAR-POTOSI.—Daily yield, 40 tons of ore, the assay value of which is \$30 per ton. This ore is taken from ore stopes and breasts in the old upper workings of the mine.

SENATOR.—The southeast cross-cut still continues in the ore vein, not having yet reached the hanging wall. The cross-cut has developed 17 ft of ledge, which appears at this point to be considerably disturbed or broken up.

HALE & NORRIS.—The north drift on the 2100-ft level is now in a distance of 310 ft and is still driven rapidly ahead to connect with the Savage on the same level. The face of the drift is still in a mixture of clay, quartz and porphyry.

GLOBE CONSOLIDATED.—A drift north has been started at the 250-ft level station, on the vein of quartz encountered at that point while sinking the shaft. This vein, where it was struck, was about $2\frac{1}{2}$ ft in width. It is gradually widening as the drift progresses, and now begins to look as though it would yet form a body of pay ore.

CROWN POINT.—Daily yield 500 tons of ore from the old upper levels. The prospecting operations on the 1600-ft level are still vigorously prosecuted with no new developments to report. The opening of the 1700-ft station is completed and a drift started to out and prospect the ledge at that point.

LEO.—Making steady progress with the work of prospecting the tunnel level. Material in face of main tunnel continues of a favorable character.

MOORE & MORGAN.—Some very good looking ore, assaying well in both silver and gold, has been found during the week in cross-cutting at or near the surface.

UTAH.—Laying the heavy stone foundations for the new and powerful pumping machinery, is making rapid progress.

WOODVILLE.—All work in the old mine is stopped for the present, and all the force that can be worked to advantage is now being employed in sinking the new shaft.

SILVER HILL.—The erection of the new pumping machinery is making as rapid progress as is possible, considering the nature of the work.

LADY BRYAN.—Sinking the south winze below the 80-ft level is making good progress, the bottom still in ore. The main west cross-cut on the 250-ft level has cut a fine body of white metal bearing quartz.

JUSTICE.—The sinking of the main incline below the 800-ft level and also the main drift south at that level, makes good progress.

NORTH CONSOLIDATED VIRGINIA.—The shaft is down 140 ft, the bottom in vein material,

carrying a considerable proportion of quartz of a fine character, which gives low assays in gold and silver.

BULLION.—The ledge developments south on the 800-ft level still continue to look very favorable for this development of ore.

NACARA.—The ledge in this shaft is looking well, the ore being of an excellent quality. The new hoisting machinery will be set up and put in operation as soon as it arrives.

BALTIMORE.—The new pumping engine has been started up and works with the utmost perfection. The work of putting in the pump rods and connecting the same with pump bob is making steady progress.

SOUTH COMSTOCK.—More and better looking streaks of quartz, clay and other vein material are coming in at the bottom, indicating near proximity to the ledge.

MINT.—The shaft is down 617 ft, the bottom in ledge matter of a very favorable character. Strong hopes are entertained of the development of a good body of ore.

MEXICAN.—The cross-cutting drifts to the eastward, on the 1465-ft level, are showing an improvement, and great faith is entertained of finding pay ore on that level.

KOSUTH.—Driving the prospecting drifts on the 350-ft level is making rapid progress, with somewhat more favorable prospects of an ore development.

OVERMAN.—Portions of the new pumping machinery are arriving at the mine almost daily, and the work of putting it in and getting ready to drain the water from the lower levels is being pushed ahead with all the energy possible.

ROCK ISLAND.—The new station at the 450-ft level is about completed, ready to start a drift to cut and prospect the ore vein at that point.

CORNUCOPIA DISTRICT.

MINING OPERATIONS.—Cor. *Elko Independent*, April 20: The Hussey has a tunnel in sixty feet, sinking shafts from the ends of the tunnel and the cross-cut drifting south. They are down eighty-one feet, working most of the way in ledge matter, and have taken out some horn-silver. Indications are good. Chloride No. 1, north of the Leopard, has a shaft and open cut down about forty-five feet through a ledge of very fine ore, milling over \$600 per ton. Has "pinched," but developments elsewhere indicate that our mines are not on the surface, and I understand that work in this mine will be resumed in a short time. Good results may be expected. The Black Diamond, under the direction of our enterprising townsman, A. D. Meacham, has a tunnel in over ninety feet, working in very good ore and showing a ledge one and a-half and two feet wide, which looks promising. The Constitution and Morning Star Consolidated, wards of the Leopard, have turned out some first-class ore, and rich developments are looked for. The Leopard is "O. K." and as safe as the Bank of California. The Rambling Sailor and other mines and locations in this vicinity too numerous to mention at present, are all claimed to be good and begin to loom into prominence. Business in Cornucopia is getting brisk, and a lively time is expected this spring and summer.

TYBO DISTRICT.

NEW HOISTING WORKS.—On the 14th instant the citizens of Tybo assembled at the Hudson shaft of the 2-G mine, for the inauguration of the new hoisting works, which were on that day set in motion and now give entire satisfaction. Toasts were drunk and speeches made by many of the townsmen to the success of the Tybo Consolidated company. The shaft will soon be sunk the required depth to drive a tunnel to the lower levels. It is estimated that at a depth of 700 feet the ledge will be struck. The furnace of the company is now being re-lined and put in thorough repair. Work on the twenty-stamp mill is progressing, and the clatter of the crushers will be heard in a few weeks. The mines at Reveille are showing good ore. Rich pockets are being found almost daily. Gila stock is selling well. Most of the people here have a little on hand and some are increasing their amount. The Gila mill will be running again on the 22d instant at its full capacity. The future of the Tybo is to all appearances a prosperous one. Underground explorations develop immense bodies of rich ore. Tybo promises to be a lively camp this summer.

JEFFERSON MINES.

NEW DEVELOPMENT.—Cor. *Belmont Courier*, April 14: In this time of drought in the way of mining news, I am happy to be able to report a new development of very rich ore in the Prussian South mine (Jefferson company). The company has been stopping for some time past between the 220 and 140-ft levels, taking out large quantities of very rich ore, from which the mill has been supplied and from which the large shipments of bullion have been made. This vein, or streak of rich ore, when first struck three days ago, was about twelve inches thick, but has become, as progress has been made in the stope, nearly three feet in thickness. And from samples of ore which I have seen, and from what I am creditably informed it assays, will mill several thousand dollars per ton, causing the whole ledge, as taken out, to yield between \$300 and \$400 per ton, without any sorting. The character of the ore is chloride and horn-silver. The prospects elsewhere through the mine are of a most cheering character, both for the stockholders and for the camp.

WINNEMUCCA MOUNTAIN MINES.

WORK AT THE MINES.—Humboldt Register, April 9: In company with our Deputy County

Coroner, Melarkey, we made a flying visit a few days since to the mines in Winnemucca mountain. We were surprised to find so many miners at work, and the vast amount of substantial work which has been done since our last visit to the "diggings" about a year ago. The Humboldt mill and mining company are working 15 men in the Pride of the Mountain mine, and are stopping ore from three different places in the mines, besides sinking and drifting in various directions for the purpose of exploring the mine. They are now getting ore in sufficient quantities to keep the mill constantly running. Al Boyer and Dick Merritt are at work on the first location south, known as the Winnemucca Chief, and are taking out some excellent ore. Last Monday they struck what they believe to be the main ledge, some 60 ft west of the old works. The ledge at this place crops out boldly, and so far as developed appears to be quite regular, containing a strata of pay ore about fifteen inches thick, which assays from one to three hundred dollars per ton.

The Champion, which for several months has been regarded as the mine of the district, is now lying idle. One-third of this mine was owned by the late J. A. Alganer, and at his death all work on the mine stopped until an administrator shall have been appointed to settle up the estate, when work will be resumed. The hills are full of busy prospectors, and we predict that before the summer is over some rich developments will be made in Winnemucca mountain.

WHITE PINE & ROBINSON DISTRICTS.

MILL BURNED.—White Pine News, April 17: The Watson company's 10-stamp mill, at Mineral City, Robinson District, was entirely destroyed by fire last Monday morning. The mill had been lying idle some two weeks, and no fires had been seen about the building during that time. Sunday night at 12 o'clock, the watchman, Mr. Woodman, went to the mill and found everything all right, and then retired for the night. A little later the Canton company's furnace whistle commenced blowing, and from the length of time it continued, startled the inmates of that quiet town from their beds. After the alarm was given, the first man at the mill was Mr. Woodman, and he states that the mill was then on fire in three different places. He did all in his power to put out the fires with a few buckets of water, but his efforts were fruitless, and in fifteen or twenty minutes the building was burned down. We are informed that the building was insured for a small amount. At the present time there is no one suspicious of this great crime.

The burning of this mill is a most unfortunate affair for the people of Mineral City, for nearly all were more or less interested in its success, and it has thrown a large number of persons out of employment. An agreement had just been made by the Watson company to work 700 tons of ore for two different companies in Ward District, which will be a serious detriment to that new and flourishing district.

Montana.

MINING SEASON.—New Northwest, April 10: The mining season is going to be a little late. The break-up seems now to have commenced, but usually heretofore in some localities mining has commenced within a week of this time, the regular "opening day" of the Pioneer company being about the 1st of April. This year, however, the snow still lies deep there. It has been going off the valley rapidly the past day or two. In '67 there were twenty inches of solid, average snow in this vicinity; on 28 out of 31 nights in March the thermometer was below zero, and he first night it did not freeze was on the 14th of April. We can beat that in '75.

Oregon.

SAM'S VALLEY.—Cor. *Jacksonville Times*, April 10: Prospecting and locating claims are yet the order of the day in this vicinity. The field of operation seems to have drifted from the north side of Evans creek to the south. Neither homesteads or entered lands escape the scrutiny of these experts. This mineral has been discovered on several homesteads and also pieces of entered land, which has given occasion for the exchanging of some pretty rough compliments between parties, of such a nature as to give offense to most any one but the good humored prospector, who seems to have more interest in the steady application of the pick than the multiplication of idle words.

Washington Territory.

QUARTZ DISCOVERIES.—Walla Walla Union, April 10: On Thursday we were shown some gold taken from a piece of quartz picked up by S. M. Wait's son, within ten miles of Dayton. The rock was beaten up by Mr. A. H. Reynolds, and there can be no doubt of the richness of the rock, but as yet the ledge from which it was taken has not been discovered. The people of Dayton think they have a "bonanza" somewhere near their town, and if a ledge of such quality as the specimen referred to can be found, it will certainly make the finder rich. We also hear of finding rich float quartz in the neighborhood of Whetstone Hollow, but can give no particulars. It has long been believed that gold-bearing quartz existed in the Blue Mountains on the headwaters of the Touchet and other streams in that direction, and many years ago the Rev. Spalding, who first visited this valley nearly forty years since, was shown rich gold-bearing quartz which the Indians had found in that section. Mr. S. always believed that there were rich mines there.

New Zealand.

ENS. PRESS:—In my former letters I have referred more particularly to the two principal Australian colonies—Victoria and New South Wales—partly because they are the most important, and partly because I am more familiar with them than with the others. I would like to say a few words, however, concerning New Zealand. This colony consists of three islands in a line with each other, and situated about five or six days steaming from either Sydney or Melbourne. Two only of these islands are of any considerable size, and one of them is largely inhabited by the aboriginal natives, called Maories. These natives are a fine, intelligent and warlike race, giving a considerable amount of anxiety and trouble to their white neighbors, but nevertheless slowly dying out. The southern island is comparatively free from them. Of the colony itself, it may be said to be the Great Britain of the southern hemisphere so far as its physical features are concerned and the enormous amount of public debt it has contracted.

The country is said to be very hilly, and abounding in minerals of every description, but too often they are found in altogether inaccessible places, so that for the present a great deal of its wealth lies buried for future generations. The climate is colder and wetter than on the Australian continent, but the people seem to enjoy it, for as a rule they are stouter and ruddier than those of the other colonies. For some time past and for some time to come, at least, there will be pretty general prosperity, by reason of the expenditures of the vast sums of money recently borrowed by their Chief Secretary, Mr. Julius Vogel, and which is being used on public works and in introducing emigrants in large numbers. Whether the prosperity will continue when all the borrowed money has been expended is a problem yet to be solved; but at all events it is, I think, pretty certain that if the new colonists go to work with a will, and especially if they condescend to let their brains guide their work, they will find ample scope for profitably employing all their energies.

From the statistics I sent you some time since you will discover that pastoral pursuits are not so actively engaged in here as in New South Wales, the agricultural interest holding a higher position here than in that colony, whilst the great seaboard offers facilities for the formation of small settlements which are not afforded by the other colonies, and the consequence is that the coast is dotted with villages, which will doubtless develop in due time into important commercial cities. Altogether, there is a bright and promising prospect for this place.

I notice that another American invention is about to be introduced here, a gentleman named Ephraim Chaquette having applied for letters patent for a machine for holding, turning, and shearing sheep. It is to be hoped, however, that he will not stop short with obtaining his patent, but that he will send some of his machines here with a competent man to work them. I make this remark because I notice that when you make inquiries as to where most of the machines patented here by English and American inventors are to be seen, what is their price and capabilities, you can get scarcely any information whatever; and on the other hand I have seen good, useful machines declared worthless simply because the person temporarily in charge knew nothing about them or how they should be worked.

Another invention, entitled "a new apparatus for tying knots," and which I understand is to be used principally for the purpose of tying the string or cord around sheaves, has been brought on the tapis since my last. Its construction is a secret at present, but that it will tie the two ends of the string into a firm knot, close to the sheaf, I can personally vouch for, as I have seen it do it.

One of the most noticeable items of information during the month has been of a very painful character, one of our best intercolonial steamers, the *Gothenburg*, 500 tons register, having been caught in a cyclone during her passage from what is known as the "Northern Territory" (of South Australia) to the Southern colonies, and driven on a reef. Of a total of nearly 110 souls only twenty-nine have been saved.

E. W.

Melbourne, March 9, 1875.

[The machine for holding, turning and shearing sheep was patented in this country through the MINING AND SCIENTIFIC PRESS Patent Agency. The Australian patents have been applied for also through this agency. Mr. Chaquette has constructed a full-sized working machine, and his tests of it have been so satisfactory that he is now making several others. A joint stock company has been organized to exploit this invention, both in the United States and Australia. Our Australian friends will in all probability be supplied with these machines at no distant day. We notice that the invention has been considered of sufficient importance to warrant an unsolicited description and illustration in *Harper's Weekly*. As soon as the inventor has completed his arrangements we will give an extended description, and possibly an illustration of this machine.—Ens. Press.]

Continued from Page 266.

it. It is put down in the Australian books as being teredo-proof. If that is so, if the piles put down in our harbor here are subject to injury from teredos, certainly one of the very first things our people ought to do would be to send over there and get some of this *Syncecarpa*. This book gives its location as exactly this same as for almost all of these eucalypts.

Myrtis communis is a myrtle tree; a small sized tree, growing in Western Asia, of some importance for its timber. It may be said to be of local value. This tree is of more importance, because it gives the name to the group. Many other species are of some value, but they are not yet utilized in commerce. Now, a word as to this myrtle. We have a little bit of a plant here which we call myrtle, a little trailing plant, and we are apt to get our idea of this order from that. In fact, I have seen some quite well-informed people who thought the little trailing plant belonged to this order. This myrtle belongs to an entirely different group, hasn't any relation to it. The "trailing myrtle" belongs to the dogbane family; its proper name is "periwinkle."

Among food plants—guavas, Malay apples, rose apples and a few others are highly prized fruits of moderate-sized trees in the hotter climates of both hemispheres. One of them—a small apple—is very delicious. We get them here only occasionally as preserves. They are never brought, I think, as green fruits.

The Aromatic Fruits.

Among these we have as the most important, the clove tree (Fig. 2), *Caryophyllus aromaticus*, a native of the Molucca islands, now cultivated in India, Ceylon, West Indies, etc. It is a moderate-sized evergreen tree, and the clove is simply the flower before it opens. You can take a clove, after soaking it in water, and by carefully opening it, see the stamens and pistils; all this parts of the flower are then very nicely shown. They are simply gathered just before they open and are dried.

Allspice is this fruit of a little tree very closely allied to real myrtle; it belongs to the species *Eugenia Pimento*, of the West Indies; now cultivated in the East Indies and countries having the same climate. In fact, some of the trees that are brought here and grown upon grounds as ornaments have a peppery or allspice-like taste, and so get this name allspice tree. The fruits are berry-like—little hard berries, and these are gathered and dried, and are the allspice.

Among the medicine products, we obtain an oil from the myrtle, that is, from the myrtle tree, *Myrtis communis*, which is somewhat valuable, and is used considerably in medicine. The pomegranate, *Punica granatum*—and this is the genuine pomegranate—is a small tree of India and Western Asia, cultivated in Southern Europe. The flowers are usually scarlet, and yield a red dye. The fruit is greatly valued in warm countries. The pulp of this is used in the manufacture of cooling drinks, so, of course, is of some value in the treatment of sick people. The rind is quite astringent, and is used in medicine and (especially that of the bitter kind) contains tannin, used for tanning the finer kinds of leather. That used in tanning morocco is largely derived from the pomegranate. The bark and roots of the pomegranate tree are also used in medicine, and are of some value, as they possess astringent properties. The fruit has a tough, leathery rind, of a beautiful deep golden color, tinged with red.

The pomegranates we have here is an ally of this squash. The name is given, I think, because of a slight resemblance in the fruit. It is not the true pomegranate at all, referred to in oriental literature, as you will find by reading carefully in these books that refer to it.

The eucalyptus is valuable for medicine, I am informed. I have been told some very strange things about it. I heard a statement that in China people living in eucalyptus groves were healthy, while others, living in places just the same, but out of the groves, were troubled with all sorts of fevers and similar diseases. [Student—"An Englishman who has been to Australia tells me the people have fevers there right amongst these trees, the same as where there are none at all."] I think it needs a great deal more investigation. The fact is, we find very few if any plants which exert a very marked influence on the atmosphere.

All these stories about plants so poisonous that birds can not fly over them

Will Not Do to Rely Upon.

When we become acquainted with the plant we find it is not so noxious as was represented. On the other hand we find that those which are so exceedingly valuable, filling the air with perfume and all that—we find these stories have to be taken with a great deal of allowance. Although a great deal of valuable matter has been written up here on this coast referring to the eucalyptus, and I have no doubt that from the tree—from this aromatic principle it contains in such abundance—we can obtain a great deal of material which will be more or less valuable, yet it will have to be worked up. There may be a very valuable substance in this tree, as quinine, or that from which it is manufactured, is in the *Cinchona*. The myrtles are ornamental and are grown largely on that account. The eucalyptus is also grown, as it is here, and several species of *Eugenia*; in fact you hardly go into a greenhouse but that you will find them, and here there are more or less of them growing out of doors. The second family,

The Rose Family.

Of the order *Rosaceae*, is made up of herbs, shrubs and trees, found mostly in the temperate climates and partly largely in the temperate zone. It includes about a thousand species and these differ so much that they have been thrown into three, and occasionally four sub-orders. I have adopted Dr. Gray's plan and we will notice these as three sub-orders; taking up the topics by themselves.

First, the food plants. I may say the first sub-order, including Almonds, Peaches and Plums, is made up of plants whose fruits are single; that is, they are single stone fruits. There is a poisonous principle running through all the species of this sub-order, which is allied to the chemical compound, prussic acid, having the same odor and, to a certain extent, the same effects. It is considered by some to be identical with this. It resides mostly in the seeds, leaves and stems. Take the seed of the peach or plum and in its green state you will get an appreciable amount of this prussic acid from it.

The almond, *Prunus communis*, is a native of Persia, and with it we are quite familiar. It is grown here in California pretty largely, and I am told by Mr. Starns that it can be grown as far north as the north line of the State, of course excepting this mountain and hill tops.

The peach, *Prunus Persica*, is a native of Persia also, and it is an opinion of native botanists that the almond and the peach are simply varieties of one original form. Compare the pits or stones of the two and you will see they are very much alike, except one being smoother than the other. While we must retain them for conveniences under different names, we consider them as originally the same. This nectarine is only a smooth variety of the peach. There are also a great many sub-varieties.

The apricot seems a little between the peach and the plum. The apricot is cultivated, or can be cultivated largely throughout almost all parts of California and would be a very paying crop.

The plum, *Prunus domestica*, a native of

The perfumes of the group are derived almost all from the roses. There are several hundred species of them. The place which may be considered as the geographical center of the roses is away over in Southern Asia, just south of the Himalaya mountains, in the northern part of Hindostan, upon the little valleys between the points of the mountains that run away out where the valley of Cashmere is. There the whole country seems to be one great rose garden. Attar of roses, oil of roses and a great many other rich things—all have roses' perfumes.

Medicines.

From blackberry root and some others we get some astringent iocidins. [Student—"What is the difference between the oil of roses and the attar of roses?"] There is a little difference in preparation in Japan, though I don't know just what the difference is.

By the way, it is hardly ever pure. The high price is a great temptation to put in all sorts of other materials.

Other plants belong to the genus *Rosa*. The rose, however, may be considered as the principal one. I suppose it must be acknowledged as the ornamental plant of the world. I think there is no question but that it stands at the head of the list.

In the third sub-order, apples and pears, we have what is botanically called a pome for the fruit. This pear, *Pyrus communis*, is a native of Southern Europe and Western Asia, found throughout Syria and the countries lying somewhat eastward of that.

The apple, *P. Malus*, is supposed to have been derived from the wild crab apple of Europe. I am not certain but it is also found in Western Asia. The quince, *Cydonia vulgaris*, is also a native of Western Asia.

Now just take a glance over these fruits. All the more important ones are from our former home,

The Home of our Race.

Away back there in Southwestern Asia. There we got our peach, and as you have seen, the plum, cherry, pear, quince and apple, all came

Fig. 1. Myrtle in Flower.

Fig. 2. Leaves and Flowers of the Clove Tree.

Southern Europe. We grow a great many varieties.

The common cherry, *Prunus Cerasus*, is a native of Southern Europe and a plant which has undergone a great deal of modification so that we hardly know what its original form was. The peach is thought to be a variety of some original; what this original was we hardly know.

The plum is *Prunus domestica*. That is the name we give it now, but then we are just as much at a loss as to its original form as in the case of the peach. You may say very safely when you give it a name, that its name is *Prunus domestica*. We give it a name, but we do not mean by that, that this form is entirely separate, that is, that it is a separate species. It is simply a cultivated form of the wild plum, which has another name in Europe.

The timber of wild cherry is inclined to be of a reddish color and is used largely for interior work and for cabinet work. I think there is no wild cherry on this coast large enough to be used. Of medicines there are few of value. The most important are derived from the wild cherry of the East. All cherry-like trees seem to have in them more or less medicinal properties. Probably it is on account of that poisonous principle; for our poisons furnish us our medicines, largely.

The second sub order may be called the sub-order of roses, etc. In this group, we have an astringent principle running through the whole.

Among the food plants we have a number of berries. The strawberry is one of the best. There are a number of varieties—*Fragaria onca*, *Virginiana elatior* and others. The *Virginiana* seems to be the best of all.

The Raspberries. *Rubus idaeus* is the European form, which is grown here as well as in Europe. *Rubus occidentalis* (black) and *Rubus strigosus* (red). Those two species are our American forms—that is they are the forms to be found east of the Rocky mountains and the one very largely in cultivation throughout the United States, also on this coast. Of blackberries we have *Rubus villosus*, an American form. There are other forms; these, however, will stand as our representative blackberries and raspberries.

from that same region, so that we have been accustomed to know them now we don't know how many ages.

The Pulse family, *Leguminosae*, of which beans and peas are representatives—a very useful order, by the way—is made up of herbs, shrubs and trees, including more than 6,000 species, standing as you see next to the composites in point of numbers.

Food plants: First, the bean, *Phaseolus*. Of this there are several species. *P. vulgaris* is the pole bean of India, also grown here. The Lima bean, *P. lunatus*, instead of being a native of South America, as the name "Lima" would imply, is a native of India, just a little beyond the home of the Arian rose. Peas belong to the genus *Pisum*; species, *sativum*, a native of the old world. There is hardly anywhere a place they will not grow and in some parts of the world they furnish the poorer classes a great amount of food. In India, there is a species under the name of "Chowler." "Soy" is in India, also the pigeon pea. Lentils are grown in Egypt. The peanut is grown in America. This peanut is a little peculiar in that it sends its pods down into the ground, after it has flowered, and there ripens them.

Forage plants: Under this head we have the tares, which are grown largely in Europe, (*Vicia sativa*) and also in the far East; that is, portions of Asia. The tares resemble, to a certain extent, lucerne or alfalfa. I have seen them grown simply as an experiment. Different clovers come under the genus *Trifolium*. The principal one is the red clover of Europe, *T. Pratense*. Another species and white clover, *T. repens*, are also largely grown in Europe. I saw quite a number of other *Trifoliums*. I take it, growing wild about here. A very great addition has been made to clovers, what is called alsike, which probably would grow well here. These are annuals, biennials or perennials according to the climate where they are grown. In the East, people used to have great discussions whether red clover was biennial or perennial. It was finally decided to depend upon conditions of climate. Lucerne, *Medicago sativa*, is grown in Europe, used as a forage plant and also for green manuring. Within a few years it has come around to us here under

this name, alfalfa. I do not know whether we will succeed in introducing it in the East or not. An attempt was made to introduce it under this old name, lucerne, from England. It failed. Now the attempt is made under this name of alfalfa. Whether it will fail or not I do not know; people seem to like the name alfalfa better than they did lucerne, and are trying it.

Timber plants: From your acquaintance with the order you would hardly expect timber plants in it, yet there are many of exceeding importance. First, acacias, which are largely grown here as shrubs, in Australia are large trees. Their wood is of great value. *Acacia melanoxylon* produces a dark colored, almost black wood in parts of Australia, which is considered almost equal to mahogany; it seems to take on a polish just about as well. Red sandal wood is obtained from *Pterocarpus santalinus*, a native of India. This wood is of a red color, very heavy, cross grained, considerably used for very many purposes. Its wood contains a good deal of coloring matter. This is obtained by cutting the wood into small chips and boiling it. Jamaica ebony, which is sometimes called "green ebony," is obtained from *Brya Ebenus*. It is a small tree some thirty feet high, yielding a hard wood of a brownish color and is used quite extensively.

Rosewood, so largely used in the manufacture of furniture, is obtained principally from two trees, *Dalbergia latifolia*, a smallish tree in India and *D. nigra* of Brazil.

This Brazilian is considered to be the best and so the Brazil rosewood is recognized as standing at the head of the list. Takes any piano—the veneering is usually rosewood. Usually only ordinary wood is covered over with a thin shaving. You need not expect to get solid rosewood, on account of its costliness. I have seen a great many piano lids of ordinary whitts pine covered over with rosewood veneering. In some cases the rosewood itself is imitated. [Student—"Is it not generally true that these very heavy woods check and split off when used in large masses?"] This is a great deal the case. It might however be seasoned and prevent this. Another thing, a lumber might be exceedingly valuable but brittle, strong in certain ways, but would not endure the ordinary wear and tear of everyday use.

Mora wood, *Mora excelsa*—and you will find it in this market under the name mora—is a native of tropical America. It is a large tree, growing one hundred and fifty or two hundred feet high, having a very fine dark brown wood, strong and durable. It is said the Mexicans use it for shipbuilding. It is also suitable for cabinet work. Yesterday I was visiting some manufacturing establishments, and found that they were using some of this mora wood. You take it up, it is almost like taking up that amount of iron. It is very full of a very peculiar, resinous material, which seems to give it its weight. In the Eastern States we have locust wood, from a native of Europe grown largely throughout all the United States. Lately, for making wagon hubs in this State, the wood of *Pseud-acacia*, or false acacia, has been used. The honey locust, *Gleditsia triacanthus* and different species, is a large tree in the Eastern United States, growing sometimes to the size of two feet in diameter, has a very heavy, firm wood, used, like the other, for making wagon hubs. The wood of this last has a dark color, not quite as dark as ordinary walnut. Among the medicinal products is liquorice, from a native of Europe. That is, the liquorice roots are gathered and used. Senna is from the far East. The Calabar bean is also from the Eastern continent.

Gums and Balsams.

First, is gum tragacanth, derived from a species of *Astragalus*, growing in Western Asia. Gum Arabic, so largely used for mudlages, is derived from a species of acacia. The Western Asiatic and a Western African species furnish the most of the gum Arabic that we have. Probably, some of these acacias here would furnish a pretty good gum. Gum kino is derived from some Indian trees. Gum copal, used so much in copal varnish, is from trees of Eastern Africa and adjacent countries. There are a number of other gums of more or less value. Balsam Peru, balsam tolu, and a number of others, are from South American trees, so that the order is remarkably full of this kind of products.

Dyes.

The one of the most importance is indigo, derived from a little plant, *Indigofera tinctoria*, found in the East Indies, and from a wild species, *I. anil*, found in the West Indies. It is a little plant, more or less shrubby, and is cut about as we cut clover hay, brought in green, thrown into large vats and a little water turned on. A fermentation takes place. In time the coloring matter turns dark, almost black. After a while the vats are drained and the matter is found at the bottom and our indigo is derived from it. It is, perhaps, the most widely used of any of the dyes we have.

Brazil-wood, used largely as a dye, is from South America, from the *Caesalpinia*. It is chopped up, and the coloring matter is extracted. Logwood, which furnishes one of the best red dyes we have, is also derived in the same way from one of the South American trees—also a number of other dyes of more or less importance.

We have further the use of the lupines here on our coast in fixing the sands of the beach. In a drive over the other side, across to Seal Rocks and the Cliff House the other day, I noticed great tracts had been tied down, as it were, and the heretofore drifting sand was secured by this growth. It was a novel use for these plants and quite peculiar.

USEFUL INFORMATION.

Lace Leather.

A good lace leather, with which to lace three-horse machine belts, as well as for innumerable other purposes, can be manufactured in the following manner: Make a strong infusion of lime water, in which immerse calf or deer skins. They should be taken out and aired every day until the hair can be easily removed. If the skins are dry they must be soaked in water and rubbed until they become as soft as they were when they were taken off the animal. This must be done previous to being put into lime water. After the hair is removed, immerse for a few days in "brau water" (wheat bran); then scrape the skins on both sides until clean, and hang up until partly dry; then oil them on both sides with fish oil (whale oil), and for want of a pair of fulling stocks pound them with a elmb, or a maul, for an hour or two; roll them up and let them lay a couple of hours; oil and pound them again; hang up and air a short time; then repeat the process of oiling and pounding—the longer and oftener the better; after which hang up and dry by the carefully managed heat of a stove. Then stretch and soften them by drawing them over the edge of a shovel; you will then have a "whine leather" that will stop all whining.

A USEFUL TABLE.—The following table, computed from actual experience, will be found very useful in calculating the weight of loads, etc.—or the weight of any of the articles mentioned, in bulk. It shows the weight per cubic foot. All that is necessary, therefore, is to measure the bulk; ascertain the number of cubic feet in it; multiply this by the weight per foot, and divide by 2,000, when you have the weight per ton:

SUBSTANCE.	WEIGHT PER CUBIC FOOT.
Cast Iron.....	450 lbs.
Water.....	62½ "
White Pine, seasoned, about.....	39 "
White Oak ".....	52 "
Loose Earth.....	95 "
Common Soil, compact.....	124 "
Clay about.....	135 "
Clay with stones.....	150 "
Brick.....	125 "

HYGIENIC BOOT SOLES.—Is there any method of making the bottoms of boots so moisture will not pass through them? This is a practical question—several methods have been tried. One is to have a cork layer between the inner and outer sole; but this thickens the boot bottom too much. Another is to cover the bottom of the boot with rubber; but the rubber soles are apt to come off, as they have to be cemented on. Still another way is to have a rubber sole with a leather margin pegged on, and this we think has proved more or less satisfactory; but it is difficult to introduce it. What is needed is that common leather should be so prepared as to be impervious to water. It can be done—who of our hygienists will do it?

HAIR can be turned blonde, or, in other words, killed, by washing in a very weak solution of soda twice a day. We happen to know that two of the leading belles of New York society owe their much-admired golden tresses to this simple recipe. A piece of soda about as big as a small hickory nut to a quart or so of water is the right proportion. Less soda gives the hair a reddish tone. Perhaps this may not be considered strictly useful information? We give it simply as a matter of general interest, but do not advocate any such interference with nature.

IMITATION OF TORTOISE SHELL.—The appearance of tortoise shell may be given to horn by brushing it over with a paste made of two parts of lime, one part of litharge, and a little soap-lye, which is allowed to dry. This is the same as the Indian hair-dye, and acts by forming sulphuret of lead with the sulphur contained in the albumen of the horn, producing dark spots, which contrast with the brighter color of the horn.

A SIMPLE, cheap and efficient protection for steam pipes may be prepared as follows: One hundred pounds of clay are mixed with water, and one hundred pounds of fine ash added and well kneaded, then mixed with one pound of hair. This mixture is well incorporated and allowed to stand until needed to use. Just before using, ten pounds of ground plaster of Paris are mixed with it. The mixture, of course, soon sets, and cannot be kept over twelve hours after the plaster is added.

POWER REQUIRED FOR THE CIRCULAR SAW.—We find the following in an exchange; "A circular saw requires one horse power for every seventy feet of lumber cut per hour. Periphery of the saw should run six thousand feet per minute. A thirty horse power driving a saw of four feet diameter five hundred revolutions per minute, will cut two thousand feet of boards in an hour, when in good order."

CRAYONS FOR DRAWING ON GLASS.—Melt together equal quantities of asphaltum and yellow wax; add lampblack, and pour the mixture into moulds for crayons. The glass should be well wiped with leather, and in drawing be careful not to soil the glass with the fingers. In timing these crayons, the point may easily be rendered very fine.

Fresco painting is so called because executed with water colors upon fresh plaster. This plaster is made of slacked lime and fine sand, and is applied upon a coating rough enough to make it adhere to it. The fresco needs a wall from materials tinctured with saltpetre, and the colors must be such as the lime does not change. When the artist has polished and made very smooth the surface to be painted, he traces upon it the previously prepared composition. The designs, of the size of the picture, are called cartoons, because prepared upon large sheets of paper glued together. Upon the wall the drawing is traced with a point of ivory or wood, or the contour of the drawing is pricked with a pin and a tampoona dipped in charcoal passed along the lines of the holes, which fixes the design on the plaster. Afterward the artist follows the tracing with a sharp pointed pencil or stylus, and the indelible contour is called the nail of the fresco.

A NEW white pigment is, according to the *English Mechanic*, demanded by the exigencies of modern industry. The paint should be as good a coverer as white lead, not easily discolored by the chemical action of gases, and, when mixed with oil, should work easily under the brush. The white pigments in general use are white lead, sulphate of baryta, Spanish white and zinc-white. The latter does not become discolored under the action of sulphuretted gases and sulphur vapors, not because sulphur gases and vapors do not form sulphides of zinc, but because the sulphide of zinc which is formed is, unlike other sulphides, destitute of color. Of course an essential quality of the new pigment must be cheapness.

AMERICAN PHOSPHORUS.—The only phosphorus works in the United States are located on the Rancocas creek, in Burlington county, N. J. At present the establishment is running at one-half its capacity, turning out about seven hundred pounds of phosphorus per week. It is a noteworthy fact that during a suspension of the former proprietors the prices ran up 25 per cent., but now have dropped back to their old figures.

PLANISHED SHEET IRON, said to be superior to the best Russian sheet iron, is said to be turned out by a company recently organized in Pennsylvania. The company has hit upon a very happy device for a trade-mark. It represents the Russian bear lying upon the broad of his back, with an American eagle crouching over and holding him helpless with talons and beak. The idea is spoken of as a very "good hit."

GOOD HEALTH.

MEDICAL LITERATURE.—The medical profession publish, in the United States, over one hundred journals. If one-fourth of this medical literature could be popularized and given to the people, instead of being confined to the profession, more good would be accomplished. Information in relation to sanitary reform, etc., published in the journals of the day, would be more beneficial to the people at large than all the medical journals of the country. We hope to see the time when police records and detailed accounts of crime will give way in our ordinary journals for articles on scientific, educational and industrial subjects.

For cold feet the best remedy is, dip them every night and morning in a basin of cold water, and afterwards rub them dry with a coarse towel. To harden the feet, tannic acid has been used with success. Employ it in the proportion of five grains to a fluid ounce of water. To correct offensive smell of the feet, bathe them in a weak solution of permanganate of potash; one scruple to eight ounces of water. For absorbing excessive perspiration of the feet, mix together several ounces of the carbonate of magnesite, two ounces of powdered calamine of alum, seven ounces of orris root, and half a dram of powdered cloves.

WHAT A MAN CONSUMES.—"Having ascertained the weight of what I could live upon, so as to preserve health and strength," says the Rev. Sydney Smith, "and what I really have lived upon, I found that between the ages of ten and seventy years I had eaten and drunk forty-four horse wagon loads of meat and drink more than would have preserved me in life and health! The value of this mass of nourishment I consider worth seven thousand pounds sterling! So by my voracity I must have starved to death fully a hundred persons; a frightful calculation, but irresistibly true."

REMOVAL OF FOREIGN BODIES FROM THE EAR.—Let the operator take six inches, or as much as he pleases of horse hair, double it into a loop, then having the patient placed on his side, pass the loop into the ear as far as it will go; turn it gently, and at first or second withdrawal the foreign body will come out in the loop. It gives no pain, and cannot do damage.—*Med. and Surg. Journal.*

ELECTRICITY AND DISEASE.—The increasing use of electricity in medical practice is worth notice. It is now applied as a remedy for toothache—a current of electricity being ingeniously applied to the seat of the pain. The instrument employed is delicate and specially contrived for the purpose. Chillsblains, it is said, are also speedily cured if treated by electricity.

How the Brain is Supplied with Blood.

The brain, says the *Herald of Health*, is supplied with blood by four arterial trunks which enter the cranial cavity at no great distance from one another and then unite into the "Circle of Willis," from which are given off the various branches that distribute arterial blood to every part of the brain substance. After traversing this, the blood returns by the veins, greatly altered by its chemical composition, especially as regards the loss of free oxygen, and its replacement by various oxygen compounds of carbon, hydrogen, phosphorus, etc., that have been formed by a process analogous to combustion. Now, if one, two or three of the arterial trunks be tied, the total supply of blood to the brain is diminished, but in virtue of the "Circle of Willis," no part is entirely deprived of blood, and the functional activity of the brain is still maintained. If, however, the fourth artery is compressed so as to prevent the passage of blood there is an immediate and complete suspension of activity, the animal becoming as unconscious as if it had been stunned by a severe blow, but recovering as soon as the blood is again allowed to flow through the artery. In fact a "stunned" state produced by a blow on the head is not directly dependent upon the effect of that blow upon the brain, which may have sustained no perceptible injury whatever, the state of insensibility being due to the paralysis of the heart and suspension of circulation induced by the "shock;" and the like paralysis, with the same result, may be produced by a blow on the epigastrium (acting on the great "solar plexus" of nerves), or some overpowering mental emotion. Again there is a curious affection termed hysterical coma, which consists in the sudden suspension of complete insensibility and the equally sudden and complete return of conscious intelligence without any other indication of brain disorder. The insensibility may come on while the patient is talking, so as to interrupt the utterance of a sentence, and the moment that it passes off the series of words is taken up and completed, without the patient being aware that it has been interrupted. With our present improved knowledge of the action of the vaso-motor system of nerves in producing local contractions of the arteries, and of liability to be influenced by those emotional irregularities in which hysteria essentially consists, we can scarcely doubt that the affection is due to temporary disturbance of this circulation through that agency. Further, if the blood transmitted to the brain, though not deficient in quantity, be deprived in quality by the want of oxygen and the accumulation of carbonic acid, (as in asphyxia), there is gradually increasing torpor of the mental faculties ending in complete insensibility.

The Heroic Treatment.

As an illustration of the power of one poison to counteract another in the human system a recent case in South Bend, Indiana, furnishes a highly important and interesting instance. We give the statement as reported in the *Tribune*, published at that place:

Dr. Harris was called to the relief of a would-be suicide, and administered the successful antidote. The person had taken between forty and fifty grains of opium, and was fast dying. He could no longer swallow, his extremities were cold and had turned black, while his respirations only numbered between six and seven to the minute. This last of itself seemed to indicate that all hope was gone, as anything less than eight respirations had heretofore been known as a sure precursor of death. As a last resort the doctor determined to try what is known as the heroic treatment, and he accordingly, with a hypodermic syringe, injected two-thirds of a drachm of nuxvomica, dissolved in a teaspoonful of water, beneath the skin over the heart, stomach, spine, and on each arm above the elbow, and on the calf of each leg. The quantity of nuxvomica would have been the death of any well man in existence, but in antagonism to the opium it was in this seemingly hopeless case an agent of life, and in fifteen minutes the man was sitting up in bed, conscious, and rapidly recovering.

Another Case of Heroic Treatment

Is told by the Springfield (Mass.) *Republican* of the way B. A. Leonard, a dumb man, residing in Southbridge, recently recovered his voice. He lost it about a year ago, while recovering from an attack of cerebro-spinal meningitis, but a few mornings since he was awakened about four o'clock by a sense of oppression and faintness. He became conscious enough to understand that gas was escaping from a coal stove, and that he would soon die unless he could get to fresh air; so, after many falls andumbles he gained the outside of the door, where he fainted, but was soon aroused by the lapping and tugging of a faithful Newfoundland dog. Then the thought came to him that his wife and child were in the house, and though he had not spoken for months he called loudly for help. His cries, united with the howls the dog set up, soon roused a neighbor, to whom he told his troubles, and again fainted, and was insensible for two hours. On recovering he was unable to talk, but the doctor, on hearing the case, caught an idea, and ordered him to visit the gas house and breathe air in the purifying-room. After spending an hour and a half there he could talk in a whisper, and has since steadily regained the perfect use of his voice.

DOMESTIC ECONOMY.

Snail Eating in France.

A correspondent of the St. Louis *Globe* writes as follows: Some of the dishes of Paris are peculiar. Snails, for example, are greatly relished. You can see them in the windows of the third-rate restaurants, and they may be had at the first-class places, but not generally. Snail-eating is an ancient Roman custom, still practised in Italy. The old Romans regarded the mollusk as a great delicacy, taking unwearied pains to cultivate it. The wealthy epicures had malleries, causing snails to be fattened with boiled spiced barley and aromatic wine. They were imported from Sicily and the Balearic Isles, and commanded a high price.

The snails in the Paris market usually come from the wine-making regions in the vicinity. They are very fond of grape leaves, on which they are found, and sent in quantities to the capital. They are sold wholesale to the Halles Centrales and other markets for from twelve to sixteen sous a hundred, and are retailed for from one to three francs a hundred, according to quality and size. The French often snack them out of the shell, as "Yankees" do oysters; but, generally, they boil them in the shell, and eat them with a batter composed of butter, pepper, salt, herbs and eggs.

There may be—probably there is—something abhorrent to you in swallowing a snail. It is all a matter of education. I once had a feeling of repulsion concerning the little slimy creature, but I have overcome the feeling. The snail greatly resembles the oyster, except that it is terrene instead of marine. If we had never eaten oysters, we should shrink from the idea of eating them, and yet we devour them with the greatest satisfaction, and count persons foolish who have not learned to like them.

There is no more intrinsic reason to recoil from a snail. I remember the first time I swallowed one. It was a year ago in Venice. I had seen the Italians undergo the suction without a shudder—nay, with gusto. I swallowed a snail by a pure effort of will, and with the greatest difficulty prevented myself from imitating Vesuvius. My imagination played me sad tricks for a few minutes. I fancied I could feel it crawling within, that the flavor was disagreeable, that it had nauseated me, etc. I was sure it was a delusion, and so it was. The cause was the novelty of the experience. I swallowed more snails, and discovered that they tasted not unlike shrimps. Once to get rid of the idea of what they were, was to relish them—at least moderately. I prefer them cooked to raw. They are excellently cooked here, and I am confident that every one who enjoys shell-fish would enjoy snails, were he left in ignorance of their name. Persons who want to cultivate their taste in this direction should begin with the mollusks boiled and served with butter.

The Burgundy snail, so called because it is found in the domains of the old province, is the largest and best in this market. It is about two inches long, and might easily be mistaken by the palate for a small oyster.

The police, who always supervise everything here, whatever the change of government, do not neglect the snail market. It is essential they should not. The animal has a partiality for unwholesome and poisonous plants, particularly tobacco and belladonna; devouring them greedily and without ill consequences. Still, if it were eaten in any quantity, after continuous feeding of that sort, its effect on the human stomach could not be healthful, and might be disastrous. The snail, therefore, undergoes inspection. Its activity and rearing must be watched for, and its condition ascertained before it can enter the gates. The mollusk is best after it has fasted for several days, and most appetizing to the stranger, doubtless, after he has also fasted for some time.

OYSTER PIE.—Fifty oysters, two eggs, two teaspoonfuls of flour, a quarter of a pound of butter, a little vinegar, chopped parsley, pepper, salt and nutmeg. Beat the eggs until they are light, drain the oysters from their liquid, put them in a stew pan, and let them simmer for five minutes. Melt the butter, and stir the flour into it perfectly smooth. To the butter add the beaten eggs, parsley, nutmeg, pepper, salt and vinegar. Mix well, and to this add the oysters. Let them simmer together for ten minutes; then put into the paste. Place in the oven immediately and bake.

WASHING COTTON GOODS with not injuring the colors is done by placing the goods in a bucket of rain water so hot that the hand cannot be held in it, and added to this as much bran as an eighth part of the fabric would weigh. Stir it lightly with a stick and let it come to a boil. Let it cool until the goods can be washed out as usual, then rinse and dry, and you will find the clothes pure and clean, and the colors bright as ever.

MINCE PIES.—Five pounds lean beef, three pounds suet, or two and a half pounds, as you like; two pounds raisins, two pounds currants, one pound citron, three or four pounds of sugar to taste, quart of good brandy, spice and lemon juice to taste.

The above is to keep on-hand awhile, and as you make the pies add chopped apples, say two medium sized ones to a pie.

Rock-Breakers and Batteries.

A rock-breaker at a quartz mill, making 170
strokes of $\frac{1}{4}$ of an inch a minute, is capable of
a preparatory crushing of seventy-two tons of
quartz—the crushing capacity of a heavy
30-stamp mill—in twenty-four hours. This,
of course, does not crush fine, but simply breaks
rock small enough to feed the battery; coarse
quartz only is passed through. It is estimated
to increase the capacity of a mill, on an aver-
age, twenty per cent.

In feeding a battery by hand a good feeder
knows the requirement of each stamp by the
sound of the stamp stroke, and keeps all fed as
equally as possible. Machine feeders are used
to a great extent and work very well. In Cali-
fornia the number of drops of the stamp per
minute varies from fifty to seventy; the lesser
number corresponding to the heavier, the greater
to the lighter stamps. A battery of twenty
stamps, weighing 550 pounds per stamp, with
sixty-one drops of ten inches per minute,
crushes forty tons of quartz in twenty-four
hours without the aid of a rock-breaker; while
a battery of twenty stamps, weighing 700
pounds per stamp, with sixty-eight drops of
ten inches per minute, crushes thirty-two tons
of the same rock. In both trials from which
these figures were deduced a No. 6 screen was
used. The results are on mill rock of average
hardness.

The proportion of power necessary to do the
work of the heavier to that of the lighter
stamps is as 850x61.700x68, and the work ex-
pected therefrom would be as near thirty-five
tons for the heavy as thirty-two tons for the
lighter stamps. But the former crush forty
tons, an additional quantity of over five tons
in favor of heavy stamps. When a rock-breaker
is used in connection the proportional result is
nearly the same. The limit of weight has never
been determined experimentally, though
stamps are satisfactorily employed in this
country weighing over 900 pounds, with a ten-
inch drop.

A Phenomenon at Yosemite.

Formation of Hail in the Spray of Yosemite Fall.

Professor Wm. H. Brewer, at the last meet-
ing of the California Academy of Sciences,
described a peculiar phenomenon which occurs
in the Yosemite valley, which is interesting,
not only in a scientific point of view, but also
to the public generally. On the 19th of this
month, in company with Mr. Galen Clark,
Custodian of the valley, Mr. Brewer visited the
foot of the upper Yosemite fall. In the winter
a great "ice cone" forms in front of this fall,
mostly, it is probable, an accumulation of
frozen spray. At the time of his visit it was
much reduced by thawing from what it was
a month since. When Professor Brewer saw it
the cone extended below the fall several hun-
dred feet, bridging the chasm to an unknown
thickness. The two persons most familiar with
it respectively estimated its thickness that day
at "sixty to one hundred feet, and nearer two
hundred feet." The outer side of this cone
slopes away from the fall; the inner side rises
like a wall in front of the sheet, which falls
mostly behind it, with deep, thundering sound.
The water flows beneath the mass and emerges
from an icy arch at its foot. The stream was
so high from the melting of the snow that it
dropped from the extreme top, not clinging to
the rounded crest, as it does when the water is
lower, but leaping out so that the actual leap
is perhaps 1,550 feet to the rocky bottom, and
to the top of the ice cone nearly or quite 1,500
feet. Over the ice cone the spray is driven
furiously by the powerful air-blast produced.

Professor Brewer says that the day of his
visit was a warm and clear one, and the time of
observation between 12 m. and 12:30 p. m., and
the fall was in its brightest illumination, as it
faces nearly south. As they neared the ice
cone certain appearances suggested to Profes-
sor Brewer that the spray which drifted over it
was (in part at least) snow. To examine this
they ventured on this cone further than strict
prudence dictated, and in the tempest which
stung their hands and faces like shot, they
found the spray in part to be hail or ice pellets.
The exact character of these pellets could not
be studied in the blinding blast to which they
were subjected. They appeared to be hard
like hail-stones, tolerably uniform in size, and
Professor Brewer estimated them at about
one-tenth of an inch in diameter. They accumu-
lated in thin sheets on the rocks which rose
through the ice near its edge, and were abun-
dantly hurled along on the ice cone.

The ice cone, which had been very white
during the winter, had been sullied by sand and
dirt carried over it in the spray of the heavy
storm of the week previous to the visit referred to.
Near its lower edge, however, were many
depressions filled with what appeared to be new
and pure snow, which they believed to be in
reality fresh accumulations of these ice pellets,
but from their position it was impossible to
examine them. Mr. Clark and Professor
Brewer, however, pushed their way back to the
rocky wall beside the fall, and as near the
sheet as it was possible to breathe or stand.
Professor Brewer says that if any of the pellets
occurred there he could not prove it. He could
not feel them, and the water so blinded him
that nothing could be distinctly seen. On re-
turning they kept on the rocks and noticed no
ice pellets there. They had no thermometer to
test the temperature of the freezing hail.

At Leidie's hotel, which is one and three-
eighths miles distant and about 1,000 feet
lower, the thermometer stood at about 52° F.
at 6 A. M.; 78 $\frac{1}{2}$ ° at 2:30 P. M.; 79° at 3:15 P. M.,
58° at 9 P. M., and 50° at 6 o'clock the next
morning. They had no wet bulb to determine
the dryness, but that the air was very dry was
proved by the rapidity with which their sat-
urated clothes dried.

When this fall was visited by the State Ge-
ological Survey, in June, 1863, the idea was
suggested that they examine the temperature
of the water above and below the fall, to see
if any actual heating of the water oc-
curred as a result of its concussion after
falling from so vast a height. The dryness of
the air was then so great that it was thought
that evaporation would counterbalance, or at
least vitiate any results that might be theo-
retically based on the mechanical equivalent of
heat; so the experiment (which would have
cost much labor and time) was not tried. The
objection to the experiment was made by Pro-
fessor Brewer himself, at that time attached to
the Geological Survey.

On seeing this new phenomenon the hypothe-
sis which immediately suggested itself to him
as an explanation was that it was due to evap-
oration; that the fall is fed by melted snow,
much of which still lies near its top; that the
great volume of ice-cold water chills the adja-
cent air to nearly thirty-two degrees; that the
air-current thus cooled, as it is drawn into and
along with this descending mass, is a very
dry current, and that its rapid saturation by
the evaporation of a portion of the spray is
sufficiently chilling to freeze drops of water up
to a certain diameter. Had the ice pellets been
portions of the ice cone, torn off from its edge
and hurled outward with its spray, such a uni-
formity of size as Professor Brewer observed
could not be expected.

Professor John Le Conte, on Professor
Brewer describing the phenomenon to him, has
suggested another hypothesis. It is that the
air carried down and cooled by the water is
somewhat condensed at the base of the fall, and
that by its expansion as it gets away from the
pressure, sufficient cold is produced to freeze
the drops.

Academy of Sciences.

A regular meeting of the California Acad-
emy of Sciences was held on Monday evening
last. The following new members were
elected: E. T. Tarbox, James P. Clifford, Al-
fred E. Regensberger, M. D., Arthur C. Tay-
lor, Charles Francis, J. R. Stanton and F. P.
Hertney. A number of propositions for mem-
bership were received and referred.

The additions to the museum were a few
specimens of salmon trout, donated by Joseph
Clark, of Mendocino county. Professor Eisen
presented specimens of pine cones from Mono.

T. J. Butler, of the Arizona Miner, sent up
a specimen of bug captured on Agua Fria
river, Yavapai county, Arizona.

The Secretary read a paper by Henry Ed-
wards on Pacific Coast *Lepidoptera*, No. 11,
giving an account of the *Sphingidae* of Cali-
fornia and adjacent districts, with descriptions
of new species. In this paper Mr. Edwards
furnishes a complete catalogus of the species
of this interesting group of *Lepidoptera* as far
as known to him to inhabit the Pacific Coast,
and offers descriptions of what appear to him
to be forms as yet unrecognized by science.
The number of species compared with those of
the Eastern States is, but small, but extended
exploration of our little known mountains and
valleys may furnish others.

Prof. Brewer read a paper describing the for-
mation of ice or hail pellets in the spray of this
Yosemite fall. This is referred to in another
column.

Mr. T. J. Lowry, of the U. S. Coast Survey,
read a paper on "Hydrographic Surveying,"
which we will shortly publish.

Col. George E. Gray offered the following
resolutions, which were adopted:

WHEREAS, The California Academy of Sci-
ences has learned of the resignation of Prof.
Daniel C. Gilman from the Presidency of the
University of California, and of his contem-
plated removal to Maryland; and whereas, the
important services rendered by Prof. Gilman
to the University and the cause of higher edu-
cation in California are known and appreciated
by the Academy; therefore be it

Resolved, That the California Academy of
Sciences expresses its appreciation and ap-
proval of the work he has accom-
plished, its confidence in his ability and its
testimony to the energy and devotion which
he has exhibited in the performance of his
duties as President of the University of Cali-
fornia. That we thank him for the services he
has rendered to the cause of higher education
here and elsewhere; that we regard his removal,
so far as it affects this community, with regret,
tempered by the conviction that in the new
field of labor upon which he is about to enter,
his varied acquisitions, combined with many
fortunate personal qualities, will prove fruitful
in benefits to the entire country; that he will
carry with him our respect as a fellow-worker
and our esteem as a fellow-member and man.

Resolved, That the Secretary is hereby in-
structed to transmit a copy of the foregoing to
Prof. Gilman and to the Trustees of the John
Hopkins University at Baltimore.

The Pacific Rolling Mills.

At the Pacific Rolling Mills, on the Potrero,
the only works of the kind on the coast, every-
thing indicates a flourishing business. New
machinery is constantly being added as the
work demands it, and improvements of different
kinds are always being made. The mill proper
originally consisted of one eight-inch or guide
train and one eighteen-inch train, the former
making round iron from one and one-quarter
to three-sixteenths, and proportional sizes of
"flats." The latter turned out round from five
inches down to one and one-quarter, and flats in
proportion. With the mill were worked six
heating furnaces, their combined capacity being
thirty tons of finished iron per day.

They have now in operation, besides the
above, one twelve-inch guide train, one three-
high eighteen-inch train for rails, one pair
coffee mill squeezers, and an eighteen-inch
paddle mill. The last two are attached to five
new puddling furnaces and are making wrought
iron from pig.

The capacity has thus been increased from
thirty to 105 tons per day: sixty of rail and
forty-five of finished iron. About one-third of
the finished iron is manufactured into different
shapes for the market, such as machine bolts,
lag screws, square and hexagon nuts, ship, boat
and railroad spikes, barrow teeth, etc. They
have now in course of construction another
twelve-inch train and a wire mill, which will in-
crease the capacity twenty tons per day or 125
tons per day in all.

The forge remains as before, three hammers
and three furnaces. They have increased the
capacity of the blacksmith shop by the addi-
tion of another steam hammer and five more
fires. It is now full of work on heavy ma-
chinery for the Comstock mines. This class of
machinery is done to order and for some time
past the mill has been very busy with it. It
consists principally of heavy pump bolts, cam
shafts, stamp stems, bolts, etc.

The whole mill is now running to its greatest
capacity full handed, employing about 350
men. They are putting up hot pressed nut
machinery which will make nuts from small
sizes up to those for two and a-half inch bolts.
The wire mill will be the first one here and
will of course lessen the importation of rods.

Microscopic Determination of Minerals.

The uses of the microscope are manifold, and
one of the uses to which it has lately been put
is the examination of minerals. It is gradually
supplanting the pocket eyeglass formerly so
much in vogue. It is found that an object seen
with an achromatic microscope, especially if it
is monocular, presents to the vision of the ob-
server its true character, and all its details are
brought out by the instrument. The simple
lens, owing to its short focus and optical
defects, gives a distorted image, and although
not by any means to be despised, cannot be
compared to the compound microscope.

The objections to the microscope have been
its cost, inconvenience of carrying and want of
skill in its use. In fact too much is expected
of the instrument and too little of the manipu-
lator. A microscope having much accessory
apparatus must necessarily be costly, and to
bring such an instrument within the means of
ordinary buyers excellence must be sacrificed.

Mr. Henry G. Hanks, of this city, who has
had large experience with microscopes, and has
made a specialty of the microscopic examina-
tion of minerals, has planned a "miners' mi-
croscope" which we examined this week and which
obviates the difficulties mentioned above. It
has been constructed with a special view to
simplicity, good optical parts, quick work, ab-
sence of superfluous apparatus, with a strong
stand and having those powers only that have
been found most useful to the miner and mi-
neralogist. By keeping these points in view the
instrument has been made so that it can be
furnished for fifty dollars, while it fully equals,
as far as it goes, the more costly instruments.
These microscopes are made by one of the
most celebrated London opticians for the
special wants of a mining community. They
are perfectly adapted for examining minerals,
ores, tailings, furnace products, so that they
are useful not only to common miners but
superintendents and others. Mr. Hanks will
send a photograph of this instrument to any
one who is interested enough to apply to him
by letter.

We feel confident that, now a microscope of
this character is on the market, more interest
will be taken in the microscopic examination of
ores and minerals. After a little study the
character of a rock will be recognized at a
glance, saving costly analysis otherwise neces-
sary. It is difficult to realize without experi-
ence how much an instrument of this kind will
reveal and how important they are in the exam-
ination of minerals. A piece of rock may be
placed under the glass and on looking at it the
observer can almost see into it, and if familiar
with the rock can recognize it at a glance. The
study of minerals under the microscope is a
new one as yet, but is advancing rapidly and is
destined to become very important to all
miners, as they can determine questions them-
selves which they are now compelled to leave to
experts.

Hydraulic Mining in California.

No. 22.

This water is supposed to be subject to any
desirable pressure, and might be used at these
drop-boxes under enough pressure to keep the
quicksilver and other matter in the drop-box
in perpetual motion, and thus assist in the
liberation and amalgamation of the gold.

A further sifting or reduction in size of the
gravel can be accomplished by straining it
through a grating with $\frac{1}{4}$ inch interstices be-
tween the bars; the refuse matter may either
be thrown at once into the main sluices, or, in
case an abundance of water is at hand, carried
in a separate box to the place of general de-
posit. Should the refuse pebbles be thrown
back into the main sluice all future gratings in
the latter must be fine enough to retain these
refuse pebbles in the main sluices, and thus to
prevent needless shifting of material.

The water which the main sluices loses by
the repeated tapping must be supplied by pure
water from the supply-pipe. The size of the
main flume or sluice must also be reduced as
the water stream and solid material lessens.

It would be advisable to supply all the
sluices for the finer or sifted gravel with riffles
made of 2 by 3 inch scantlings, which are not
only considered the best gold-catchers, but are
easily removed and replaced, and durable
enough for the washing of fine gravel.

In the history of gold mining the washing
process can claim priority over all others, no
matter whether the gold was found in the sands
of a river or in a solid ledge of quartz. If in
the latter the solid quartz was first reduced to
sand, and then treated like river sand, by
washing over sloping platforms covered with
blankets or skins, in which the small parti-
cles of gold settled, while the lighter sand
flowed off with the water.

The platforms of our under-currents are only
a repetition on a far larger scale of the above-
mentioned primitive mode of gold-washing,
and they illustrate well the soundness of the
principle: to pour the gold-bearing matter in a
shallow stream, over an inclined platform,
provided with a rough surface, on which the
small particles of gold can be caught.

Condensed from an article by Charles Waldeyer, in
the last Annual Report of the U. S. Commissioner of
Mining Statistics.

A New Roasting Furnace.

Ernest Heilgendorfer of Cerro Gordo, Inyo county, California, has invented a roasting furnace for the proper oxidation and chlorination, and for the extraction of gold, silver, copper and other metals. Mr. Heilgendorfer sends us a description of this furnace, which we give in his own words as follows:

When a minute particle of ore is exposed to hot oxidizing or chlorinizing gases, this particle is instantly oxidized or chlorinized. Far different is the result, when a bulk of ore is roasted in a common fire. The smoke of the fire is reducing and works directly against oxidation. The roasting gases also find too small a surface to act upon; the interior parts will therefore at once cake to larger or smaller globules, which resist even a long continued roasting.

When only a simple oxidation of sulphurets is intended, these caked lumps retain some sulphur and are generally afterwards separated by sifting and roasting over again.

For chlorinizing purposes the ore used to be mixed with salt, which may do well enough for the chlorinization of silver; not so, however, for other metals, that almost constantly accompany silver ore. The salt producing chlorinizing gases during the whole roasting process is an additional obstacle to oxidation. There will consequently remain in the roasted pulp a number of combinations and single elements, imperfectly oxidized, which are most injurious to amalgamation. Chloride and sub-chloride of copper consume the iron millers of the pane and prevent grinding; chloride of lead envelopes chloride of silver, preventing its amalgamation, lead also imparts a soap-like quality to the amalgam; arsenic renders quicksilver foamy; free sulphur, left unburnt in a smoky fire, changes quicksilver into cinnabar. The chlorides of base metals, especially of copper, are amalgamated together with the chloride of silver, and deteriorate the fineness of the bullion. Even iron enters some way into the amalgam, (perhaps as protoxide), and disturbs retorting. These and other difficulties will frequently puzzle the mill-man and cause, in many places, roasting to be a disagreeable operation of doubtful utility.

All these disadvantages, however, are merely due to imperfect roasting. A correct roasting process must not only volatilize sulphur, arsenic, antimony, etc., and chlorinize gold and silver, but it must also work up all the chlorides, such as chloride and protoxides of the accompanying base metals and turn them out as oxides. The oxide of copper, lead, bismuth, iron, etc., do not cake, nor do they exert chemical influence on the machinery, nor on the quicksilver; and what is equally important, they do not enter into amalgamation. The bullion produced is therefore fine silver and gold, however late the ore may be. At the same time, the consumption of quicksilver diminishes, because various causes of its detriment have been removed.

The question, how roasting may be done with such correctness, is already answered above. Every particle of ore must be exposed to hot currents of purely oxidizing and chlorinizing gases. Under such conditions the effect is instantaneous and complete, and roasting finished before the pulp reaches the bottom. Though some furnaces complete chlorinization in the receiving bottom, there is no chance there to improve the lacking oxidation. I will now show how my furnace accomplishes the task.

(a) To convert the dry crushed ore into a fine dust. Cold pulp is sticky and liable to form little balls, some of which would fall through the fire entirely crude. In a moderate heat, however, the pulp becomes more and more thin, and almost as easily flowing as a liquid, and partly by sifting, partly by falling some distance through the air, will form a dust shower no minute particle of which may escape the roasting gases.

(b) A clear fire, free from smoke, of the highest oxidizing power, and of any required volume and temperature, is formed by alternating currents of air and burning gases. The quantity of oxygen introduced must not only be sufficient to consume the smoke, but there must be beside a surplus provided for the purpose of oxidation.

(c) For chlorinizing purposes the upper part of the fire is mixed with chlorinizing gases, the lower part being always purely oxidizing. In this way the ore dust falls first through chlorinizing and afterwards through oxidizing gases, whereby the chlorides of base metals are changed into oxides. Chloro-silver is unchangeable, chloro-gold is decomposed and metallic gold left.

The adjoined sketch shows that the pulp, coming from the hopper in small and constantly renewed quantities, falls first into the inclined and revolving cylinder, *E*, of about 12 feet in length by one-half foot diameter. The pulp is heated during its passage through the cylinder to the desired degree of temperature and fluidity, and passed on to the sieve, *F*, where it is spread and screened by machinery. The shaft, *G*, connects the sieve, *F*, with the furnace below, and is from five to ten feet high, for protecting the sieve from the fire and giving the pulp a chance to drop in a fine

spray or dust shower. The pulp reaches the fire, at the mouth of the shaft which consists of alternating fire and air currents and eventually also of other roasting gases.

In our sketch the fire is formed by four currents of air and three currents of gases of combustion, with a combined thickness of six feet, sufficient for the majority of cases. If the single fires were burning on common grates, a great deal of heat would be lost before reaching the furnace. It is therefore a saving of fuel to use gas generators, the gases of which will not burn before mingling with air. Only one of the fires, the lower one, has a common fire place; being next to fire bridge, no part of its heat is lost, and it serves to ignite the gases and to prevent explosions. This arrangement offers also an opportunity to finish roasting, when required, under an increased heat. As a general rule, though, roasting needs far less fire than millmen often suppose. Oxidation is itself a burning process, and when properly done will produce considerable heat of its own.

I wish here to remark that the engraving is not so much intended to be a plan for building as to illustrate the principle upon which this furnace is based. It will, for instance, be more convenient to supply the two upper fires from one common gas generator, which can also feed a small flame, to pass through the interior of the heating cylinder.

In the passage between the fire bridge and the upper arch all the different gases are thronged together, whereby the air is heated and the fire purified from smoke, and all reducing elements.

For chlorinizing purposes the ore is not mixed with salt, but the chlorinizing gases are prepared separately, and, together with air,

few cases in which extraction may be adopted to great advantage.

Oxidation of Sulphurets, not Containing Arsenic or Antimony.

Sulphurets of copper will best be roasted to oxidize and given over to extraction. Connecting a lead chamber with the roasting furnace, the resulting sulphurous gas may be utilized for sulphuric acid, with which to extract the oxide of copper. The bluestone produced is already marketable; it can also be oxidized again and smelted to metallic copper.

Sulphate of iron can, when it pays, likewise be manufactured from pyrites.

These sulphates can be procured directly from the ore. Lowering the temperature of the fire, by letting in more fresh air and mixing at the same time the fire with steam, (as also with sulphurous gas when the ore does not contain a sufficient quantity of sulphur), the sulphates of copper and iron are formed directly, and can be extracted with water.

Silicates and oxides of copper want only crushing to be extracted with sulphuric acid.

Doing the extraction under steam pressure the quickness of the operation will be suitably increased.

Chlorinization.

Ore containing arsenic and antimony can be thoroughly roasted only by volatilizing these two troublesome ingredients. The silver contained in the ore is at the same time advantageously changed into chloride of silver; gold is left in a metallic state. The accompanying base metals, after having been roasted to oxides, are no longer nuisances; some of them, especially copper, may even contribute to the profits of the enterprise.

The advantage of extraction will be seen by

HEILGENDORFER'S FURNACE FOR ROASTING ORES.

introduced into the upper part of the fire. This method will not only favor the final oxidation of base metals, but also make chlorinization entirely independent of the character of ore. A considerable saving of salt will be gained besides.

As the pulp during its fall through the fire is carried away to a certain horizontal distance, as indicated by dotted lines, the fire bridge is correspondingly advanced into the furnace and extended upwards in an inclined diagonal direction, to which the upper arch or ceiling is made parallel. The outlet, *A*, which leads to the dust chamber and chimney, is lying in a continued line of said passage. This construction gives the lower part of the fire the same efficiency as the upper part, and also counteracts the pressure of the falling pulp.

As the fire hardly finds any obstacle to overcome, the draught can be slow, and the quantity of dust will therefore be a minimum.

The roasting process from beginning to end can be overlooked and controlled with a single glance, and any disorder may be promptly discovered. In regular working order the fire is perfectly transparent, becoming perceptible only as a bright shine. A most lovely sparkling is caused by the vigorous action of the roasting gases, and various colors of a surprising beauty indicate the different substances contained in the ore. These colors, which are not visible in a common fire, will become an excellent criterion to the roasting process.

After having passed the fire, the roasted pulp drops into the receiving space, *T*, from where it may be removed hourly by a trap door, or constantly by a screw.

Though a correct roasting process greatly improves both smelting and amalgamating, it affords for numerous classes of ore a still more desirable mode of reduction, viz.: the extraction. The following lines will briefly show a

an example of ore that, as frequently happens, contains a great many different metals. After the roasting process has volatilized sulphur, arsenic, antimony, tellurium, etc., there may be left in the roasted pulp, gold, chloride of silver, oxides of copper and iron, as also a small percentage of oxidized lead, bismuth, etc. From this mixture the gold can be extracted with chlorine water, and the chloride of silver with hyposulphate of soda (or lime). Neither of these liquors dissolves any oxide: the products are therefore fine gold and fine silver, every one separate. Ore containing gold and silver together could so far never be successfully roasted. Gold wants little salt, silver a great deal. With this excess of salt the gold combines in some way, not exactly known, and becomes inaccessible to either amalgamation or extraction. Using, as I do in my furnace, chlorinizing gases instead of salt, the danger of this loss is avoided and the simplest mode given to separate the two metals. The oxide of copper remaining in the twice extracted pulp can now be extracted with sulphuric acid.

An analogous treatment of chlorinization and extraction may, even in the absence of gold and silver, be given to copper and nickel ore, when accompanied with arsenic and antimony.

As sulphuric acid is always wanted for extraction as well as for preparing hydrochloric acid from salt, a lead chamber for the fabrication of sulphuric acid appears to be a most necessary addition to the roasting furnace. Almost every class of ore contains sulphur; the cost of sulphuric acid will therefore be a mere trifle. The other liquors required for extraction, can also be prepared at such prices that extraction will, probably in every location, be cheaper than amalgamation.

A difficulty to extraction arises from a high

percentage of lead. The oxide of lead combines with sulphuric acid as well as with the hyposulphate of soda. A small percentage of lead, however, would scarcely be felt. When the portion of lead increases the chlorosilver may be extracted with a boiling solution of salt, or with ammonia, which have less dissolving power and therefore work slower. To extract copper or nickel from ore, that contains much lead, would take disproportionate quantities of sulphuric acid.

Considering the enormous value of noble metals yearly lost by the usual methods of reduction, it is certainly an object worth attention how these losses might be prevented or lessened. To talk of free milling ore, when the wet process realizes only 65 per cent. of silver, as is the rule in the first silver producing place of the world, is a mere illusion, which ought to be given up at once. It seems more reasonable to calculate the expenses and profits of an improved method. I am confident the mode of roasting I have tried here shortly to describe, will become a remedy to some serious disadvantages under which a permanent branch of the mining industry is laboring. A judicious examination will prove the justice of this opinion and ratify all that has been stated here.

The Emma Mine.

The Vice-Chancellor of England has decided against the petition to wind up the Emma silver mining company, and has ordered a meeting of the shareholders to express their wishes in the premises. The winding up of the company would be compulsory and would prevent the shareholders from realizing anything. So says a dispatch recently received. We do not see, if the mine is worked out, how the shareholders will realize anything, whether there is a compulsory winding up, or whether they continue to work. It seems to us that if they have no more ore to count on they had better shut the mine down, sell the machinery, and stop talking about it any more. If they continue to work with no encouraging prospects and lose more money, they will have no one to blame but themselves. The Vice-Chancellor does not doubt that the concern was originated in fraud and says expressly that the shareholders have been cheated; that the mine is not worth working, and it is his opinion that a compulsory winding up is best; that if anything could be got out of the original offenders by a suit in the United States, an official liquidation commission, appointed by a British Court, can conduct the suit better than anybody else. Glass, council for 21,000 shares, however, insists that there is some hope of getting something from the mine. His sanguine clientele desire to supplant the present Directors with new ones, and go on. Glass insists that the company has no debts and is getting out \$10,000 in silver monthly, which pays expenses.

Several mining engineers of ability and reputation reported that the mine was worked out and stated that the future of the mine depended entirely on virgin ground, as in any new mine. Clarence King, Director of the U. S. Geological Survey of the 40th Parallel; E. S. Blackwell, Manager of the Ophir mining and smelting company, of Utah; Andrew Murray, F. L. S.; and George Attwood, Manager of the Emma; all told the same story and told the stockholders they must spend large amounts of money before there was even a chance of realizing anything more from the mine. King said "the great Emma bonanza, the object of such wide celebrity, the basis of such extravagant promises, is, with few insignificant exceptions, worked out, and the future of your company is hung on a mere geological chance which may be eternally against you, and if in your favor, may only be secured by wise expenditure of much time and money." This was as far back as June, 1873. The statements made in all these reports have been borne out by the results, though interested parties have endeavored to make it appear otherwise. Any one interested may look back in the files of the Press, June 6, 1874, and see by diagrams on what Mr. Attwood based his calculation that the ore body was worked out.

There is no doubt but that there are parties who would like to get hold of this famous mine as agents for the English stockholders, and who would endeavor to get the stock up again so that some of those interested could sell to the confiding public. We think, however, that this will be a difficult undertaking. The proposed meeting will no doubt be a stormy one, but we hope to see good judgment prevail and see the stockholders get out of the whole business without further loss.

The new pumping engine of the Consolidated Virginia mine will have a forty-inch cylinder, a seven-foot stroke and a capacity of 600-horse power. The hoisting engines will be two in number and will each have a capacity of 200-horse power.

A vein of hematite iron has been struck, on the line of the Utah Western railway, at the point of the mountain.

At Bollionville the Raymond & Ely folks are rushing things through so as to prepare the thirty-stamp mill for immediate work.

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C, it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; L, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First street, S. F. 24v23

THE KNOX & OSBORN

QUICKSILVER FURNACE.

THIS FURNACE REDUCES CINNABAR, (ROCK OR FINE EARTH,) AND

WORKS CLOSER TO AN ASSAY

At LESS COST per ton than any other furnace. It will work continuously Twelve to Twenty-four months without stopping.

NO MAN HAS EVER BEEN SALIVATED

Otherwise affected by the mercury about the furnaces, either in operating it or making repairs. For full particulars, plans, etc., apply at

NOS. 19 AND 21 FIRST STREET, SAN FRANCISCO.

We refer any party desiring a good furnace to either of the following Mining Companies, where the furnace may be seen in successful operation:

- The Manhattan Mine in Napa County.
- The Redington Quicksilver Mining Company, Napa County.
- The California Quicksilver Mining Company, Napa County.
- The Phoenix Quicksilver Mining Company, Napa County.
- The Etna Quicksilver Mining Company, Napa County.
- The Ida Clayton Quicksilver Mining Company, Sonoma County.
- The Annie Belcher Quicksilver Mining Company, Sonoma County.
- The Geyser Quicksilver Mining Company, Sonoma County.
- The Cloverdale Quicksilver Mining Company, Sonoma County.
- The California Borax Company (Sulphur Banks), Lake County.
- The Abbott Mine, Lake County.
- The Buckeye Mine, Colusa County.
- The Cerro Bonito Mine, Fresno County.

KNOX & OSBORN.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 18 Cents Per Pound. SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally.

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES and DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES and DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES and DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES and DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 60 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to 1v29-3m

CAST STEEL SHOE & DIE CO., Room 1, Academy Building, S.F

GIANT POWDER.

Patented May 26, 1868.

THE ONLY SAFE BLASTING POWDER IN USE.

GIANT POWDER, NO. 1,

For hard and wet Rock, Iron, Copper, etc., and Submarine Blasting.

GIANT POWDER, NO. 2,

For medium and seamy Rock, Lime, Marble, Sulphur, Coal, Pipe Clay and Gravel Bank Blasting, Wood, etc. Its EXCLUSIVE use saves from 30 to 60 per cent. in expenses, besides doing the work in half the time required for black powder.

The only Blasting Powder used in Europe and the Eastern States.

BANDMANN, NIELSEN & CO.,

General Agents, No. 210 Front Street.

LEFFEL & MYERS, MANUFACTURERS OF LEFFEL'S AMERICAN DOUBLE TURBINE WATER WHEELS, Spherical and Horizontal Flumes. Also all kinds of Mill Gearing especially adapted to our Wheels.

PRICES GREATLY REDUCED. COMPETITION DEFIED. For Satisfaction it has no equal.

Addresses, or Call on LEFFEL & MYERS, 306 California St., S. F. Send for Illustrated Catalogue and New Price List—sent free.

HORIZONTAL FLUME, Patented April 1, 1873.

TREADWELL & CO.'S

(IMPROVED)

Upright Safety Engines and Boilers.

(MADE BY THE NEW YORK SAFETY STEAM-POWER COMPANY.)

We would call particular attention to the graceful form and simple mechanism of this engine, and also to the fact that it is the greatest strength and rigidity with a given amount of material. The Boilers, which are of the Upright Tubular style, with internal fire box, are of the best material and workmanship, and are all tested to 150 pounds per inch. The heating surface and area of grate are in excess of the quantities usually allowed for the same power, and it is actually required, while in cases of emergency these boilers can be depended on for more than their rated power. The Engine is not fastened to or upon the boiler, and is therefore not affected by expansion, nor are the bearings over-heated by conduction, or the heat from the boiler. The fly-wheel being at the base secures perfect steadiness under all high speed, which is necessary for economy in fuel. All the parts are made of the best material, and the Engine is itself as a Portable Engine and Boiler, or the Engine can be detached from the boiler and run independently, if required. Its main points are simplicity, safety and economy. For printing offices, laundries, bakeries, ranches, small repair or machine shops, or for hoisting, wherever a small and safe power is required, they are peculiarly adapted. Over 500 are already in use.

JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivalled.

For rapidity pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the greatest number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setters made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

VOLUME XXX
Number 18.

The Bruckner Revolving Furnace.

The Bruckner revolving cylinders for roasting ores, engravings of which accompany this

article, are now used at a number of mills in Colorado and New Mexico for the purpose of roasting and chloridizing silver ores, with satisfactory results, even from those cylinders of small size, erected before the many improvements of recent date. The larger improved cylinders are used at the Tennessee reduction works, Silver City, Grant county, New Mexico, and those which were built in 1871, at the celebrated Caribou silver mills and mines, Colorado, a mining enterprise which proved so satisfactory as to have been sold some time since to a Holland company for a very large amount. These cylinders, as now constructed by Messrs. Lane & Bodley, of Cincinnati, Ohio, are shown in the accompanying cuts, in which Figure 1 is an elevation in perspective, Figure 2 a longitudinal and Figure 3 a transverse section. Our correspondent, W. C. Quimby, sends us the following description of the furnaces:

The exterior of the cylinder is a sheet of boiler iron, twelve feet long by five feet six inches in diameter. The ends are partially lined with similar material, leaving in the center a circular opening about two feet in diameter, surrounded by a flange projecting several inches. Upon one side is placed an opening closed by a hinged door. Upon the outside of the cylinder are bolted three bands as shown in Fig. 1, in which the section of the first is square and that of the third semi-circular; the second or middle band is a strong spur gear.

Passing through the cylinder are six pipes parallel to one another, in a plane at an angle of fifteen degrees to the axis of the cylinder; these pipes also lie in this plane at an angle of thirty to thirty-five degrees to the longitudinal axis of the plane, as shown in Fig. 3, where the internal arrangement of the cylinder is seen, a perforated diaphragm being formed through part of the cylinder by means of perforated plates placed between the above described pipes, the plates being held in place by longitudinal grooves upon these pipes.

The entire cylinder is lined with brick (common building brick have been found to answer the purpose very well), the brick being placed in the following manner: The entire side of the cylinder is covered with one layer, laid flatwise, thus forming a lining about two and a half inches thick; there is an additional layer extending from each end of the cylinder about fifteen inches to the center of where the nearest pipe passes out; the additional concentric layers are added thereon, until the

cylinder is contracted down to the size of the opening in the end, which is also lined, and each layer falls short of the preceding one about two inches, thus giving the end linings a conical form, the entire lining being laid in a

rotary motion is given to the cylinder by means of a pinion placed under the cylinder and gearing into the spur wheel band. Upon the other end of the pinion shaft are placed ten bevel wheels, into which gear two match

screws, by which it can be moved horizontally to or from the center line of the machine, thus giving entire control of the lateral and perpendicular adjustment of the cylinder which they support.

The circular flange of one end of the cylinder loosely projects into a fire box best seen in section to the left of Fig. 2. The other end projects into an opening communicating with dirt chambers and a chimney. There is placed in the bottom of the fire a shoe projecting into the cylinder, which catches such dirt as may fall back and returns it into the cylinders in lieu of allowing it to escape through the crevice between the cylinder flange and the opening into the fire. A door is placed in the fire, opposite the opening, through which the interior of the cylinder and its contents can be readily examined at any time.

Method of Operating the Cylinder with Refractory Silver Ores.

A fire having been kindled in the fire-box, the cylinder is allowed to slowly revolve until heated to a dull red, and is then brought to rest with the door on top. In this position about 4,000 lbs. of pulverized ore, and 200 to 400 pounds of salt are introduced; the door is closed and securely fastened and the cylinders are made to revolve at the slower speed of from one-half to one turn per minute. The fire is so regulated that after an hour's time the sulphur contained in the ore commences to burn, the ore in the cylinder being retained at a dull red for some time. (In those ores containing a large amount of sulphur, little or no additional fuel is required for desulphurization.) During the whole of this and the subsequent operation, the inclined perforated diaphragm causes the heated ore to traverse alternately backward and forward the entire length of the cylinder, also sifting it through the flange, thus insuring a uniform heating, mixing and exposure to chemical action.

The diaphragm, in the meantime, is protected from destructive action of heat by the cooling effect of external air circulating through the pipes, and from corrosion by the formation of a basic scale or coating, resulting from reaction of the iron, pulp, etc.

The desulphurization being completed, the heat is gradually augmented to a full red. The pulp soon assumes a spongy appearance, technically known as "woolly," in consequence of the double decomposition of the sulphates (formed during desulphurization) and salt (chloride of sodium), liberating chlorine gas, etc. After an hour's time, or soon as a sample taken from the cylinder evolves the odor of chlorine unaccompanied with that of sulphurous acid, which indicates that the chlorination is complete, the door in the cylinder is opened, and the cylinder revolved by the more rapid moving gear, and the chloridized ore is quickly

Continued on Page 289.

Fig. 1. THE BRUCKNER REVOLVING FURNACE.

Fig. 2. Longitudinal Section through Axis of Bruckner Revolving Furnace.

are grooved upon their periphery to loosely fit the semi-circular band, thus holding the cylinder longitudinally in place. The other two friction rollers are made without a groove and bear upon the square band, thus accommodating themselves to the expansion and contraction of the cylinder, or any irregularities in form. These things are shown in Fig. 1. Ro-

ing the speed of revolution of one or the other of the bevel gears as may be desired. Inasmuch as by wear or settling the axis of the cylinder may possibly be thrown out of the proper line, the following means of adjustment are provided, but not shown in any of the engravings, viz.: Each journal box of the friction rollers is held in position by adjusting

the speed of revolution of one or the other of the bevel gears as may be desired. Inasmuch as by wear or settling the axis of the cylinder may possibly be thrown out of the proper line, the following means of adjustment are provided, but not shown in any of the engravings, viz.: Each journal box of the friction rollers is held in position by adjusting

CORRESPONDENCE.

Letter from Reveille.

[From our Regular Correspondent.]

EDITORS PRESS:—The Gila company appears to be on the high road to success, to judge by the prosperous condition of its mine, quantity and character of ore now being mined, and the excellent results obtained from the first lot of ore milled.

The mill was originally fitted up for wet crushing, and for purely quartz ores this process would have suited well enough, but for the Gila ores it would not answer, consequently the Superintendent resolved to turn it into a dry crusher, and has accordingly shut down for the purpose of carrying out as rapidly as possible the necessary alterations. These will, of course, absorb much time on account of the delay attendant upon procuring the proper materials from Belmont, the nearest point at which lumber, castings for drying kiln, etc., could be procured. Brick, also, had to be burned, ere any steps were taken in the matter, and since these will be ready for use by the 19th, it is hoped the mill will be ready to resume operations by the 25th inst. at the farthest. The sooner the better, for there are several hundred tons of first-class ore mined awaiting reduction. The forty-eight tons which have been worked by wet crushing, produced \$12,000, equal to \$250 per ton, and this, too, it must be remembered, without being sorted or graded, as is the custom where ores are found to be as rich as these. These forty-eight tons were taken at random from a pile of 300 tons lying on the dump, that have been extracted since the purchase and incorporation of the mine on the first of last February. It cannot be denied that these are highly successful returns, yet, however inspiring, I am now fully satisfied that future workings will give even greater products than the above; for these 48 tons were mostly taken from the first lot extracted from the apex of the vein. There are now in the neighborhood of 400 tons of this same quality of ore mined. I visited the mine on the 10th inst., which was company pay-day, and I am free to confess that I was very agreeably surprised with the outlook.

Work has been energetically pushed ahead in every quarter since I last wrote, and brilliant and all though the prospects were then, I cannot avoid saying that they have been largely augmented since that period. I notice by the issue of the Press which came to hand yesterday, that I addressed it last on the 13th ult., a much longer space than I was aware had elapsed.

The inside winze mentioned in that letter as having been sunk 30 feet on the vein, has been drifted from a distance of 60 feet south along the lode, through ore of a remarkably fine grade, without encountering any dead spaces in that extent of ground. The vein, as now worked, is fully five feet between foot and hanging wall, and these are among the best defined in structure, smooth, clean and uniform throughout, that I have ever seen outside of the Two G mine at Tybo, of which I will soon again have something fresh to give to your readers, now that the new hoisting works are nearly completed. From two samples of ore taken by myself from the face of this south drift, assay values of \$375 and \$289 were obtained, and these were got from a class of ore that to my judgment did not look like being as rich as it has proved. But it is very deceptive, and differs from any of the Nevada milling ores with which I am at all acquainted.

The bullion ranged in fineness from 650 to 915, and one or two bars showed 989, thus showing how small a percentage of the base metals there are associated in place with the ore. Thirteen bars have already been shipped per Wells, Fargo & Co.'s express from Tybo, consigned to Daniel Meyers of your city, at whose office they can be seen by the public. There is now ready and partly soaked enough of ore to produce \$100,000 worth of these shining bars, which in a few weeks (days) will begin to flow from there to still further add to the wealth and grandeur of San Francisco. From the upper tunnel, which courses south parallel with the above winze, there is at present taken some very fine ore from a stratum four feet thick, and the indications are strongly in favor of the opinion that it will soon effect a junction with the main portion of the vein, for it is now opening as though a bonanza development was to be the next thing to transpire.

The tunnel run from a point on the east to cut the ledge a depth of nearly 100 feet is rapidly approaching completion. It is now in over 112 feet, and hopes are entertained that the next 15 feet run will strike the vein, and this is reasonable to suppose when the character of the ground through which it is being driven is considered, for it shows that the ore is not far distant.

There have been several new and important strikes made in the vicinity of the Gila lately, the ore assaying well and giving evidence of soon becoming plentiful. But of these I will

speak again when not so hurried as at present, and with this assurance I will close these hastily scribbled remarks. J. D. P.

P. S. Since writing the foregoing, one of a very high grade has been struck in the outside tunnel at a distance of 120 feet from its outer orifice. The ledge is perfect in formation as far as uncovered, and the ore clean and apparently very rich. This important development adds to the value of this property immeasurably, and sustains the high opinion which, as I have shown in the Press, I have from the first always entertained of it, and it unquestionably is, from present appearances, destined to become, and that too at no distant day, the greatest and grandest mining property outside of the bonanza that lies under the giant shadows of Mount Davidson. But of this more anon, from J. D. P.

Reveille, Nevada, April 15.

Locomotive Engineering—"The C. P. Huntington."

EDITORS PRESS:—About two years ago C. P. Huntington met with a terrible accident, and got most fearfully smashed out of form and shape. I do not mean the gentleman who bears that name, and who occupies so conspicuous a position in railroad affairs on this coast, but his namesake, the engine Number 1, belonging to the S. P. R. R. Number 1, or C. P. Huntington, was one of the engines that had the misfortune to be engaged in the collision that occurred on that road, when one engineer, White, was killed, and Jerry Sullivan, and old McSawyer and other employees of the road were badly injured, and if I remember right, there were some three or four passengers killed also. The engines met face to face while they were going at the rate of twenty-five miles an hour, so that it can be easily imagined that they must have been pretty severely handled; indeed they were literally shattered to atoms. Engine Number 2 was repaired right away, but engine Number 1 was stowed up for a time, and it was not until the last few months that the administration determined to rebuild it again.

Last week it was finished, and certainly a peculiar looking craft it is. The engine is of a most unique pattern, there being but one or two others like it on the coast. The front of the engine rests on a truck somewhat in the same manner that other locomotives do, but there is but one pair of driving wheels, which are located immediately in front of the fire-box, while the hind part of the engine and the tender, which are joined together, rest on a single truck, which brings up the rear. The engine has been rebuilt in the most thorough manner by Messrs. Wilson & Smith, and all the latest improvements in locomotives have been put on, that go to make a first-class engine. With the exception of one or two plates in the centre of the boiler, it is entirely new, being built at the boiler shops of the company, by Mr. J. Kelschaw. There are also new cylinders, steam-chests, steam-pipes, dry-pipes, and indeed, nearly all the main parts of the engine, with the exception of the wheels and a few other items, are new, so that as she stands to-day, it is more as a new engine than one that has been simply rebuilt. One of the Westinghouse air brakes has been put on, but the position of the air drum, and the various pipes leading thereto, tend rather to detract than otherwise from the looks of the engine, giving it a clumsy and muddled appearance. It has been painted throughout in the most sombre colors that could possibly have been thought of, without making it black altogether, and looks in striking contrast to the gay and bright looking engines that come out here from the East. With the exception of the bottom part of the smoke stack, which, strangely enough, has been painted a flaming red, the engine and tender is of a dark brown color, relieved at places by the brown having a greenish tint given to it.

On the side of the cab is the name of the engine, C. P. Huntington, put on in gold leaf, and Mr. Wilson, the painter, has placed some very pretty designs directly underneath, with the words, "Enterprise, 1863," and on the next panel, "Progress, 1875," intending to show the enterprise and indomitable energy that in 1863, began to work and fight its way onward, in spite of all the difficulties that obstructed its path, and now in this year of 1875, we can mark the extensive progress that has been made, and the great results that have been achieved in so short a time on this new line of road.

Taken altogether, it is a peculiar looking thing, blending as it does, in its own being, some of the crude ideas that prevailed at the time it was originally built, and also carrying with it some of the latest and best improvements that human skill and thought have been able to suggest in the engineering world. S. C.

NEW MODE OF MARBLING METAL.—A new process for ornamenting metal surfaces has been recently invented. It consists in plating, electro-plating, or otherwise covering a plate, bar, or ingot of soft metal with a thin film of harder metal, and then rolling out or pressing the ingot into a sheet; whereby the coating is broken into irregular forms, and a marbled appearance produced on the surface of the sheet.

Worms in the Teeth.

At the last meeting of the San Francisco Microscopical Society, among other microscopical slides, Mr. C. Mason Kinne presented a slide which was mounted with what were claimed to be worms taken from diseased teeth, and in presenting this slide Mr. Kinne read a short paper, which explained the matter and is given in full.

Worms (So Called) in Teeth.

To the student in microscopical, who feels a just interest in original investigations—original at least so far as relates to himself—there is always a field, wide and extended, which waits his attention, yet oftentimes after careful and patient study, the application of tests, and comparison with the obtainable results of others, he finds what is apparently new to have been looked into and treated just as carefully by some plodder before him. To my mind, the time spent in such cases is never lost, and the satisfaction found in obtaining definite results by microscopical analysis is materially enlarged if found to agree with the deductions of others unknown to the time.

Whether the slide I present this evening, mounted as it is with objects which seemed to demand more than a cursory examination when brought before me, will prove to be new or not remains to be ascertained, and for that purpose and to give the members of the Society the information I have obtained that they may, if needs be, pursue the matter further, I make these statements.

A gentleman, well known for his genial qualities as a pioneer, his executive ability as an underwriter, and his desire for the advancement of science in a general way, suffering from an intolerable neuralgic toothache, casually learned of a person who declared, unhesitatingly, that the affliction could be removed, when proceeding from diseased teeth, without the use of the dentist's cruel forceps and loss of serviceable molars. The printed advertisement of this philanthropist reads as follows:

"TOOTHACHE CURED WITHOUT PAIN.—A PERMANENT CURE IN FROM SEVEN TO TEN MINUTES!—I use a steaming process, with a purely vegetable matter, that can be eaten without the least harm. I can convince anyone having the toothache, by relieving the pain in a few minutes, and showing them the worms on the receiving iron as they drop from the teeth. I have taken as many as thirteen worms from the teeth of a single person. I am no doctor, and do not pretend to cure but this one thing. I have cured a great many, but never charged anything up to the present time. No cure, no pay!"

Suffice it to say, in the spirit of despair a trial was made, and after allowing the smoke from a quantity of the medicine, placed on a heated iron, to enter the mouth by means of an inverted funnel, some twelve or fifteen worms (so-called) were found attached to the inner side of the funnel, and handed to me for investigation, which resulted as follows:

The objects, which certainly appear to the casual observer much like round, white worms, average one-fourth of an inch in length and one-thirtieth in diameter, with a tough integument quite regularly striated longitudinally. Its substance is of a waxy consistency and somewhat moist. Treating the "worms" with heat, water, ether, liquor potassae, acetic, nitric and sulphuric acid, benzine and "Mille's test," brought out various results. The cell structure was plainly shown in several instances, and I exhibit herewith drawings from the microscope, of the same.

Without entering into details, the invariable result of each of the tests made was conclusive, and I feel certain that there is no animal matter in the "worms," but that the objects are a peculiar formation arising from the substance used for the cure, which is the secret of the owner and jealously guarded.

There can hardly be a doubt but that the object is entirely of vegetable origin, and from the shape and reticulation of the cells cannot be of fungoid growth, and never had anything to do with diseased teeth. Whether this fact will detract from the permanent result in those cases where the pain has been allayed by the smoke or steam from the substance, remains to be seen.

The object and drawings of its cell structure were observed with interest, which was much enhanced by a verbal statement from Dr. Harkness, who fully confirmed the deductions of Mr. Kinne, and stated that some years ago he had studied the phenomena, arrived at the same conclusions, and having an opportunity to carry the investigation still further, ascertained that the remedy used was onion seed mixed with butter, which, on the application of heat, caused the germ to separate from its investment and lodge against the damp sides of the funnel; and further stated one essential point to be that the patient should be convinced that there were worms in the teeth, so that success depends upon the credulity of the subject of the experiment.

CURIOUS EFFECT OF COAL.—A curious effect of coal is related to have occurred in Meadville, Pa., recently. A strong bottle had been filled with water, and a cork placed in the nozzle. During the night the water froze solid, and the expansion pushed the cork from its place and formed a column of ice above the top of the bottle three inches in length and half an inch in diameter, the cork still remaining on the top of the shaft of ice.

A Home For All.

Every living thing should have a home. "Foxes have holes," and all burrowing animals excavate domiciles suited to their need; why should man, of all other animals, neglect to provide a home for himself and family—or allow himself to depend upon his neighbor for such a necessity? Endowed to the highest degree with the faculty of "inhabiteness," why should he either choose or be compelled to curtail his natural desire for the luxury or rather necessity of a home? It should be one of the first duties of every man to procure for himself either a temporary or permanent home—one that he should be able to call his home, and from which no power or circumstances should be permitted to drive him, save important public necessity, or fire, or flood. Especially should this be the case with every married pair. A home of his own fixes a man as few other things can, and takes away both the necessity and desire for the too prevalent necessity of "moving," a ruinously costly practice, and one which is alike destructive of prosperity or pleasure to both parents and children.

The lack of ability to provide a costly or elegant home should be no excuse for a total neglect of the duty under consideration. An extremely humble home in proprietorship is far more honorable and praiseworthy than a more costly and showy one the possession of which depends upon the caprice of a landlord. At the same time no man should be content to live in an old rookery who is able to provide his family with a comely and convenient home.

Many who own homes are quite too indifferent to give their domicils that care and attention which is necessary to ensure a proper degree of comfort and love for the homestead. Children should be taught to love and feel an honest pride in their homes. Inducements should be held out which will naturally lead to such a result. Ornament your homes, as you may be able to do from time to time. A few shade and ornamental trees, a little flower-garden, a tidy fence around the homestead, cost but little and add wonderfully to the love which will be begotten in a son or daughter for their home.

As a general thing it is difficult to place money where it will insure more pleasure or profit than when invested in a home. Better spend money in building and improving a home than for thousands of things of which we soon tire or finally throw away as worthless.

What Constitutes a Perfect Home.

That which combines the most instrumentalities for comfort and domestic enjoyment, is the thing that should be most sought for in a home. That is the first and most rational end in dwelling. In order to secure a reasonable degree of comfort the sanitary conditions of both house and locality should be taken into consideration. The house should be so placed as to secure for its rooms a proper amount of sunshine—modified, of course, according to climate. In the hot valleys shade is more desirable than on the sea coast. Too much sun can scarcely be thrown into a house in San Francisco.

Ventilation is another important matter which should be taken into consideration. Of this there should be a perfect control, in a manner to avoid drafts directly upon the inmates. Every human being requires a copious and constant supply of pure, fresh air; to ensure good or even passable health. The kitchen conveniences should form a prime consideration in every dwelling. Much depends on the arrangements for wood and water, and for sink, cooking and closet room, as regards the ease and facility with which the work in the family may be done. Practical housekeepers know that it takes nearly twice the labor to do up a given amount of work in rooms house than it does in others. Who can tell the amount of fretfulness, ill-temper, to say nothing of unnecessary exhaustion and sickness which an unhandy house occasion?

In building much depends upon the selection of the best spot for building. The same money will often build a good house on one spot which will be required to build a very indifferent one in another. But be your choice what it may, the house and site should be adapted to each other, and to the wants of the family. An elevated site best secures a fresh, dry atmosphere and general health. A valley or low place is much more generally subjected to the unhealthy influences of fogs, miasmas, etc. Good water is always one of the first essentials.

If you propose to put up anything like an expensive house, an architect should be consulted by all means. Such an expense may perhaps be avoided when a mere cheap, temporary house is to be provided, until financial possibilities will enable you to do better by adding on or tearing down. We propose to notice this subject further in a future number in which the architectural considerations will be more fully discussed.

At the Miner's Foundry they are making six drills for the Diamond drill company in this city. They are also making two steam engines for service at the Comstock mines.

SCIENTIFIC PROGRESS.

Condensation of Air on the Surface of Platinum.

After taking the weight of a clean platinum vessel, then wiping it thoroughly with a dry rag or soft paper and replacing it on the pan of the balance, it will be found to have lost weight; if of the ordinary size used in quantitative analysis, it will be found to have lost two milligrammes or more. If allowed to remain on the balance for fifteen or twenty minutes, it will be found to have recovered its weight. This change has usually been attributed to moisture; but it has recently been clearly established that such is not the case. The following is the result of some accurate experiments:

A new flat-bottomed capsule, four centimetres in diameter and two centimetres deep, having about fifty centimetres square of surface inside and outside, was first thoroughly cleaned by boiling in a solution of caustic soda. After thorough washing in distilled water it was heated to redness, allowed to cool, and in one hour weighed. It was now taken from the balance and wiped with clean filter-paper, taking care to touch, as far as possible, all parts of the surface, without using any violent friction. After being submitted to this operation it was replaced on the balance, and it was ascertained to have lost two milligrammes, and after being allowed to remain for twenty minutes its original weight was restored.

The vessel was now transferred to a drying receiver over sulphuric acid, and allowed to remain six hours; placed on the balance it weighed exactly what it did when placed in the drying receiver. It was now wiped as before, and on being replaced on the balance had lost two milligrammes, which it recovered, as before, in fifteen or twenty minutes.

The vessel was now transferred to a receiver in which the air was saturated with moisture from wet paper, placed on the glass support.

After six hours the capsule was placed in the balance, when it was found to weigh just the same as it did when it was introduced into the moist atmosphere. A dry atmosphere or a moist atmosphere was then shown to have no effect in producing this temporary loss of weight in the capsule.

From these experiments it shows very clearly that there is air condensed on the surface of platinum that a little rubbing will remove; but it will soon return to the platinum after this treatment. The importance of this fact will be manifest to the analytical chemist, and make him cautious about taking the tare of his platinum vessels too soon after wiping them.

POPULAR TREES AS LIGHTNING CONDUCTORS.—Who has not heard of the perils which environ people who live near rows of tall Lombardy poplar trees, such as were formerly so common in many places in New England and which are still cherished for their beautiful stateliness in some parts of Europe. Their great height and tapering form seems to fit them especially as a medium for conducting the electric fluid earthward. The danger arises from the tendency manifested by the fluid to glance off before entering the ground, and commit sad havoc in and about the adjacent dwellings. To avoid the necessity of sacrificing these ornamental trees to the well grounded fears of their owners, M. Colladan, of Genève, has published an essay on the subject of turning them into properly constituted lightning conductors by inserting in the lower part of the trunk a metallic rod, which he connects with the earth by a chain, so that the fluid can not leave the tree to dart at any object placed within a short distance, as at present so often happens.

CURIOUS ACTION OF ELECTRICITY ON IRON.—We made brief reference some months since to the remarkable phenomena first observed by Prof. Gore, a distinguished European electrician, which consists in the very perceptible twisting of a bar of iron by the joint effects of currents of electricity, passing longitudinally through and also around such a bar by means of the insulated wire of an enveloping helix. Subsequent experiments have shown that such twisting may be made to reach full one-quarter of a revolution. It has also been ascertained that both currents are necessary to the development of the phenomena. Either current, when applied separately, simply produces the ordinary effect of magnetizing the bar. The direction of the twist is definitely related to the direction of the current in the helix. In order to produce the fullest effect the currents must be simultaneous. When they are successive a perceptible twist results in a lesser degree.

THE FLIGHT OF BIRDS.—Birds have a more or less instinctive knowledge of engineering. When a bird commences its flight, if there is any wind, unless forced to take wing too suddenly, it will generally lean toward the wind at the start. The reason for such action is obvious. In order to readily ascend, each stroke of the wing must come in contact with a fresh volume of air, which could not be the case unless the bird either made a progressive movement or the air itself was wafted past the bird, as in a wind current. The downward impulse of successive strokes would be greatly impaired in their efficiency by heating largely upon air which comes in to fill the space from which the air has been removed by the preceding stroke. Hence, the onward movement of a bird plays an important part in the efficiency of the action of the wings.

Important Researches on Explosive Substances.

Recent experiments have shown that two different kinds of explosion can be produced in all explosive substances. The first is *deflagration*, the second is *detonation*. The deflagration of dynamite (gunpowder) is quite harmless; while its detonation, as produced by fulminate of mercury, develops an explosive force four or five times that of ordinary gunpowder. Gunpowder is no exception to this rule. When its deflagrating power, (ordinary discharge by a fuse) is represented by 1, its detonating power, when properly fired by fulminate of mercury, is 4.34.

Roux and Sarrazin have recently been making some careful experiments in this direction, which are reported in *Comptes Rendus* as follows: The reciprocal of the weight (due corrections made) of each substance, which when exploded in one and the other manner sufficed to send similar cast iron shells, gave the relative explosive forces. Some results of the experiments are given in the following table, the explosive force of gunpowder ignited in the ordinary manner being taken for unity:

NAME OF SUBSTANCE.	EXPLOSIVE FORCE.	
	2nd Order.	1st Order.
Mercury fulminate.....	1.00	9.28
Gunpowder.....	1.00	4.34
Nitro-glycerine.....	4.80	10.13
Gun Cotton.....	3.00	6.46
Floric Acid.....	2.04	5.50
Potassium picrate.....	1.82	5.31
Barium picrate.....	1.71	5.50
Strontium picrate.....	1.55	4.51
Lead picrate.....	1.55	5.94

Of the highest practical importance is the discovery of the detonative explosion of gunpowder induced by the detonation of nitro-glycerine (itself set off by the fulminate of mercury); for the force of the explosion is more than fourfold greater than that obtained by igniting gunpowder in the ordinary manner. (The increased force of gunpowder and gun cotton, when exploded by the agency of detonation, was fully demonstrated by Ahel six years ago). The authors observe that the mass of the substance employed for exciting detonation must usually bear a certain proportion to that of the substance to be exploded, but in some cases the action is propagated throughout the latter when once up at any given point.

A READY METHOD OF SHOWING THE ABSORPTION OF HYDROGEN BY PALLADIUM.—In the beautiful and important investigations of Graham upon the absorption of hydrogen by palladium, he describes a very pretty method of making this absorption very apparent to the eye, viz., to take a strip of thin palladium, place wax or other non-conducting and pliable substance on one surface of the strip, and then attach it to the proper pole of a galvanic battery, and plunge it into water acidulated with sulphuric acid, when the hydrogen that is evolved at that pole, instead of escaping as gas, is absorbed by the palladium, which now bends and coils up on itself in virtue of the expansion of the exposed side.

This same result I have been in the habit of exhibiting in my laboratory, with a small piece of very thin palladium about one and a half centimetres wide, and eight centimetres long. Light a small sized Bunsen burner, hold the piece of palladium in the upper part of the flame; it will get red hot, but remain in the same form as when introduced in the flame. Lower it now into the flame, until the unburnt gas from the center of the flame strikes the bottom of the metal; when it will immediately coil upwards, and can be made to double on itself. Carry it back to the upper part of the flame, and it will straighten itself again. There are some interesting chemical questions connected with this experiment that are worth working out, and at some leisure moment I will look into them; as for instance, the absorption of gas at the high temperature, and as to whether or not simple hydrogen is absorbed, the palladium thereby decomposing the hydro-carbon, etc.

MUSIC FROM NOISE.—A curious instrument has been exhibited before the Academy of Sciences, which is called by its inventor an "analyzing cornet." What we describe as noise is of course made up of an infinite number of musical notes, and these the cornet is designed to analyze just as a prism separates a ray of white light into its colored components. In appearance, the instrument is described as resembling a trumpet, having a nozzle to fit to the ear instead of a mouth piece, and furnished with holes, like a clarinet. Provided with one of these instruments, it is said that the roaring of a cataract or the howling of a tempest may be resolved by the listener, skilled in the necessary fingering, into the softest melody, which is heard, however, by himself only.

The chromo-lithographic process is described as follows: In place of using a special stone for each color, necessitating as many separate impressions as there are colors, the entire subject is drawn upon a single stone, and a proof is taken on a thin sheet of copper. This sheet is then cut out carefully according to the desired contour of the colors, and upon each of the portions is fixed a solid block of color, previously prepared. The whole is combined into one form, and is printed on an ordinary lithographic press, all the colors at once, the moisture of the sheet being sufficient to take off and hold the colors as the sheet goes through the press.

MECHANICAL PROGRESS.

Railway Platforms—a Crying Evil.

Among the innumerable plans ever being proposed and patented for saving the lives and limbs of railway passengers, says a New York journal, it is strange that one which requires no patenting should be lost sight of. We allude to the remodelling and levelling up of platforms at railway stations. Inquiries into the causes of the numerous railway accidents of last year have elicited the fact that many of them were, directly or indirectly, due to the unpunctuality of trains. How essential, then, to adopt all measures likely to promote good time-keeping! The varying height of railway platforms is a deadly enemy to punctuality. How are travelers—unless previously trained as acrobats and "gymnasts"—hurriedly to climb up to or get out of carriages, the floors of which are sometimes three feet, or three feet six inches above the platforms? Yet these facts have to be attempted by passengers of both sexes on many lines of railway, and especially during the excursion season. Muscular young men may succeed in the operation, but the old and the halt, as well as the very young, and ladies who have regard to decency, find it impossible of accomplishment. They must be helped in or helped out, or carried too far, or left behind, or, worse than all, meet with an "accident." Delay to the train is, at any rate, inevitable, and delay is the parent of unpunctuality and disaster. When four hundred or five hundred persons have to enter a train almost simultaneously, as frequently happens during the summer months, why should they be compelled to run the risk of breaking their arms, legs or necks? Common sense would suggest that every possible facility should be given for ingress to and egress from the carriages. In place of this, it seems to have occurred to the constructors of railway stations in general, that their best plan was to create stumbling-blocks, so as to make both processes as difficult and perilous as possible. The "rule of thumb," now generally denounced by scientific men is the only rule which has prevailed in the formation of platforms at railway stations. Scarcely two of them correspond in height on any single line of railway. Some are high, others are low, and others are medium. Very few indeed are what they ought to be, namely, level with the floors of carriages. It should be made as easy to enter or leave one of the latter as to step from the parlor to the hall or passage of a dwelling house.

[The evil complained of above is as serious in this vicinity as it is in New York, and hence the above is equally as applicable here, as there.—Eus. Press.]

A VALUABLE INVENTION.—Monsieur C. Jeanne, late an officer of the French Navy, is the inventor of a self-acting apparatus intended to show and register the speed of a ship, the number of miles made good, and the actual courses steered. It is to the last point the inventor more particularly invites attention. Attempts have been previously made, with more or less success, for the self-registering of speed, etc., but the automatic registration of a ship's course is something entirely new. The helmsman cannot vary a quarter of a point without its being shown. This part of the apparatus can be disconnected from the others and used alone, and from the practical experience of the inventor there is good reason for believing in the practicability of his invention. In the case of collisions, although the apparatus cannot, of course, prevent them, it would truthfully register the course steered by each ship, which is now one of the most debatable points with which official assessors have to deal, for this invention claims to give truthful evidence, and would thus far materially assist a correct decision being arrived at as to which vessel was right and which wrong, thus preventing maritime insurance companies from being unintentionally defrauded. This is a matter well worth the attention and consideration of underwriters, for with such a truthful "tell-tale" on board the wrong people could not well be called upon to pay.

AN IMPROVEMENT FOR LAYING DOWN STREET RAILS.—The President of the Third Avenue Railway Co., of New York, writes as follows to the *Scientific American*:

One of the greatest needs of street railroads is some simple and economical invention to keep the rails, where they meet, in a level condition; or, in other words, to prevent the end of the forward rail from sinking below the end of the rear rail. The device at present used is an iron plate placed under the junction of the two rails; but this does not entirely prevent the evil. I invite the attention of inventive minds to this subject.

BENDING HEAVY IRON.—It is now possible by the aid of hydraulic machinery to bend iron shafts of twelve inches in diameter to any required shape. Incredible as this statement may seem to an expert, crank shafts are now so made, instead of by the slow, laborious and expensive method of forging. The bent shafts are also said to be much better than forged ones, from the fact that the fiber of the metal runs in one direction continuously, whereas in forged ones it is often across the line of strain.

Fire-Proof Pillars.

The introduction of iron columns is now the leading characteristic of modern ordinary construction. Hardly a store-front is erected but we see a few slender pillars supporting an immense superstructure of stone or brick. The columns are all that can be desired under ordinary circumstances. They are strong and sturdy; they do not occupy much space. Their great drawback is in case of fire. A column that will support a certain given weight when cold will, when heated far below the melting point, give way under a fractional part of the weight, or if when heated it is played upon by a stream of cold water it will fly to pieces and down comes the superstructure, crushing in its fall the contents of the building and perhaps also, sundry luckless firemen. We see in an Eastern paper that a patent has been secured by the Rev. Geo. Bruce, of Aurora, N. Y., for an iron column in which these defects are to a great extent removed. It is described as follows:

The invention is a simple one, and consists in applying the principle of the fire-proof safe to an iron column. As in the case of the common iron pillar, a solid cast-iron column sustains the whole weight of the superstructure, but outside of this solid column is a thin cast-iron shell, and the space intervening between the outer shell and the inner column is filled with plaster of Paris, the non-conducting properties of which are well known. No weight is allowed to rest on the outer shell or the non-conductor that is used as filling, their only mission being to protect from the effects of heat the real support of the building, the inner column. These columns will be surrounded by an iron T girder, which is enclosed in a fire-proof casting of a similar nature, and the junction between the pillar and the girder is so formed that only the protected portion of the one touches the protected portion of the other, while the casing forms a tight joint, making the fire-proof armor complete. These columns are intended to take the place of the ordinary iron columns in ornamental fronts of buildings, as well as the interior of large warehouses where such supports are needed.

What is Steel?

Mr. Ralph Crooker, of Boston, and well known throughout the New England States as a rolling mill man, asks and answers the above question very concisely as follows:

"Steel.—A combination or an alloy of iron, that will forge, harden and temper."

There are various kinds of steel—such as carbon cast steel, tungsten cast steel, chrome cast steel, cyanogen cast steel and titanium cast steel; and several other metals have been alloyed with iron to make steel.

There is also blistered steel, which is made from malleable bar iron, by a process called cementation; German steel, which is made directly from the ore, and sometimes from pig iron, in the Catalan forge; and steel which is made by other processes.

The line between cast iron and steel is—when it is capable of being forged it is steel; and when it will not forge, it is cast iron. And the line between malleable iron and steel is—when it will harden and temper, it is steel; and when it will not harden and temper, it is malleable iron.

Cast steel will harden slightly when it contains from 0.25 per cent. to 0.30 per cent. of carbon, and ceases to be capable of forging if it contains much more than 1.75 per cent. of carbon.

BATTLE WIRE.—Some statements of Dr. Van der Weyde, in the *Manufacturer and Builder*, will be found of interest in connection with the use of telegraph wire, which it seems is not always what it should be. He tells us that the wire in use by the New York city police and fire alarm telegraph consists of steel and copper, was erected by contract, and cost the city at the exorbitant rate of \$1,360 per mile. The Western Union telegraph company uses an ordinary galvanized wire that cost it scarcely \$50 per mile. The heavy snow storm of December 20 last broke the city wires in every direction, and in such a way that they were an utter wreck, and the telegraph services of the Police and Fire departments were totally suspended until repairs were accomplished. At the same time the wires of the Western Union suffered little or no damage. In other words, the city was swindled with worthless telegraph wire at a cost twenty-six times greater than that by which a private corporation furnished itself with a serviceable article.

IRON FURNITURE. made of hollow iron, has recently been introduced into Germany. A large factory devoted to this class of manufacture has recently been established there. Ribbon iron, of the best quality, is taken and converted into tubing in pieces of about eight metres long, which can be bent cold into any form suitable for the making of bedsteads, chairs, tables, etc. Hollow iron is stronger than solid iron, such as that usually employed heretofore, and possesses this special advantage, that rivets hold better, and that it does not itself break so easily, as is frequently the case in solid iron, which gives way where there is a flaw.

KRUPP OUTDONE.—Quite a sensation has been produced in military circles in Vienna recently by some brilliant trials of new Austrian guns in steel and bronze. They proved superior to Krupp's cast steel guns.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

HYDRAULIC MINING.—*Amador Ledger*, April 24: A few days ago we paid a visit to the St. Mary's gravel claims, to observe the working of the Little Giant, now in operation, and from our observations made upon the ground, the immense power of 500 inches of water and 240 ft pressure, the vast quantity of earth, gravel and stone carried off in a given space of time, we came to the conclusion that we saw for the first time hydraulic mining in the county. Although the Giant stood at least 100 feet from the bank of gravel, yet the volume of water passing through the nozzle would strike the bank with astonishing force, hurling over and over boulders that it would require a stout man to move. In playing upon the bank for a few minutes, immense slides of earth and gravel would occur, which in an incredible short time would be passing through the sluices. We had no means of accurately ascertaining the number of tons removed in a given space of time, but we think we are within the bounds of reason when we say, 500 inches of water through the Little Giant, will remove in 12 hours more dirt, gravel and boulders, than could be picked down, shoveled up, and removed by a thousand men in the same length of time. The St. Mary's claims are now in fine condition, and present a very flattering appearance, and will undoubtedly prove valuable property.

CALAVERAS.

PROGRESSING.—*Calaveras Chronicle*, April 24: Work upon the quartz ledges recently discovered at Mosquito is progressing favorably, and the town wears a livelier appearance than it has before for years. Rich rock is being taken out and prospects for the development of paying mines are good. Labor upon a number of older claims in that vicinity is also being well remunerated.

REN HILL.—Work is being pushed steadily ahead in the hydraulic claim on Red hill, near the Buckeye. The claim is not yet sufficiently opened to work to advantage, but it is being got in shape as rapidly as circumstances will permit.

HAPPY VALLEY.—Things are running smoothly in Emerson's hydraulic claim in Happy Valley. New ground that prospects well has been reached, and piping goes on without interruption. It has been a long, tedious job to open the claim, but the mine will last for years and amply remunerate the owner for his labor and outlay.

CONTRA COSTA.

COAL.—*Antioch Ledger*, April 24: Richard Milie, of Somersville, has discovered a vein of coal on Corcoran's ranch, south of town, distant six miles. It is reported to be a two-ft vein, and preparations are being made to work the same the present summer.

WEST POINT DISTRICT.—Chick & Co. just cleaned up a large quantity of ore, at the rate of \$58.50 per ton. The large overshot wheel and hoisting works of the Josephine are nearly ready for action. The Champion main shaft is now about 140 ft in depth; ore as rich as ever. The whistle of the Anderson Flat mine has resumed its familiar scream. It is said that a new Superintendent will take charge of the mine, and that it has changed owners. The Good Faith tunnel is driven ahead steadily. The tunnel will not alone drain five veins, which yielded well in early times, but will also give the owners about fifty vertical ft of backs on each vein. A number of teams are employed hauling ore from Mentzel & Co.'s mine to the custom mills. Contractors are sinking on the old "Cheno," owned by F. Novella & Co., of San Francisco. A large and rich body of decomposed ore has recently been discovered near the Soap Root gulch.

FRESNO.

THE NEW DISCOVERY.—*Mariposa Gazette*, April 24: The accounts received from the mine recently discovered on the Fresno, corroborate fully the statement of the richness of the mine first published. The vein is about 35 feet in thickness; the extremely rich streak is from six inches to two feet wide, and pays from \$400 to \$800 dollars per ton, while the remainder of the entire vein will pay from \$40 to \$50 per ton at the point where the work has been and is now being carried on. We would hesitate to give publicity to such a statement as the foregoing were it not that we have been so frequently assured that it is no exaggeration. The rock is of a blue, flinty character, such as miners say rarely contains gold. The parties are now down about 30 feet, and the rock is richer at the bottom than any other part of the vein yet uncovered.

INYO.

ANOTHER ENTERPRISE.—*Panamint News*, April 22: To-day we made a visit to the new trick-yard just commenced by the company, where we found a large number of men actively engaged in moulding brick, putting up machines, preparing the yard, building roads and grading for a kiln. There are now thirty-six men employed, giving a lively business aspect to that portion of the town. The yard is under the supervision of C. B. Ricker, foreman, who informed us that the work of moulding was commenced yesterday, when over 4,000 brick were turned out. Three mud-mixing

machines, run by horse-power, are already in position, and a fourth will be added to-day. The material, found right at hand, is a clay loam, and from all appearances will make a very good article of burnt brick. The water is led in pipes to each machine, doing away with the labor usually experienced of either pumping or hauling it. When everything is in readiness—which will require but a day or two more—Mr. Ricker thinks they will be able to turn out fifteen thousand molded bricks a day. This kiln will contain one hundred thousand. Another will be started as soon as the first is finished. Wood for burning is found on the hill just above the yard, only requiring little labor to throw it down. The brick now being manufactured are to be used in building a huge stack for the company's mill, in setting the four large boilers, and for the Stedfeldt furnace. Some two hundred thousand will be required.

THE JESSIE MAY.—The Panamint mining company are pushing the work on their mines vigorously. The tunnel is progressing rapidly, making four feet per day, and the shaft on the lead is down fifty ft, and the vein steadily increases in width and richness. Superintendent Dolan is about to ship ten tons of ore to San Francisco to test its value by milling process. As an evidence of the confidence felt in the mines of this district, Superintendent Dolan has purchased for his company another one, called the Vanderbilt, which is situated near the noted Jessie May. This is believed to be a very valuable mine, the parties from whom Mr. Dolan purchased having refused an offer of \$7,000 from Senator Stewart some months since. The Panamint Consolidated company are now in possession of six mines, all showing well.

DARWIN DISTRICT ITEMS.—*Cor. Inyo Independent*, April 24: The miners feel sanguine that they have located in the best smelting district on the coast, and say they defy any camp to show as much ore on the dumps, for the amount of work done, as is to be seen here in Coso district. The mines are showing up well, and on every dump may be seen a large pile of first-class ore. It does seem strange that some one does not put up a custom furnace, I am certain he could get more ore than he could possibly smelt, and at a reasonable figure. As for the facilities for working, they are better than any other smelting district I have ever seen—and that is every one of note on the coast. Plenty of wood but ten miles off, and down grade the entire distance to haul it. As for water, Mr. Beaudry told me yesterday that he could furnish 150,000 gallons any time there is a demand for that quantity. And, in this connection, let me say that his first load of pipe arrived last night. Laying it will begin immediately. He has the ditch for it completed to within plowing distance of town, and can finish it in two days.

KERN.

KERN MILL.—*Kern County Courier*, April 24: We saw a statement a few weeks ago that a 70 stamp mill, the largest and finest in the State, was to be erected on the Consolidated Virginia. This county claims the largest and finest mill in the State. That on the Big Blue at Kernville has 80 stamps, and that of the Consolidated Virginia cannot by any possibility be better constructed or finished.

NAPA.

COPPER ORE.—*St. Helena Star*, April 22: Ten tons of copper ore were shipped last week by Friedberg & Co., from their mine near the mountain mill house. The ore averages 25 per cent. Messrs. Parks & Michel, near the same place, have a well defined lode of the same metal, south and joining the Friedberg mine; they will commence taking out ore as soon as they can finish their tunnel, which they are running to tap the lode 70 ft lower than the bottom of the shaft now sunk; their ore is high grade black oxide, running from 25 to 40 per cent. copper, and from \$3.50 to \$15.00 gold. A Middletown company have struck the same metal two miles northwest from them, on the same range. As yet they have not developed enough to say what they may have.

NEVADA.

NEW YORK HILL.—*Grass Valley Union*, April 24: Splendid ore has been struck in the New York hill tunnel, at a distance of 900 ft from the mouth of the tunnel. The ledge there is two ft thick and shows gold and heavy sulphurets. Superintendent Snyder is proud of his success and he is right.

HOWARD HILL MINE.—This mine is being worked under the superintendency of Captain John White. The work of pumping out and repairing the old works is progressing favorably. A ten inch pump is now at work, and about 300 gallons of water every minute are thrown to the surface. An additional pump will be in place at work to-morrow, and then 430 gallons a minute will be pumped out. A good looking ledge, parallel to the original Howard hill ledge, has been discovered on the company's ground and several rich specimens from it have been sent to San Francisco. Howard hill is about to be a good mine.

WORK AT NEW YORK HILL.—*Foothill Tidings*, April 24: In company with our friend J. D. Meek, we visited this mine on Thursday, and found superintendent Snyder driving things along as fast as possible. At the new hoisting works all is life and bustle. The new incline shaft is nearly completed to the tunnel or adit level—will probably connect this week—and is a fine piece of work. It has two car tracks and a pump and foot way. The quartz shows free gold quite frequently and the crushings they have had proclaim unmistakably the presence

of this precious metal; the last 500 loads worked out a round \$45,000, or over \$77 per ton. At present the force is working at a great disadvantage, but in the course of two or three weeks the machinery will be running, the heavy hand work will be over, and Old New York Hill will resume its ancient position of one of the heavy bullion producing mines of Grass Valley.

PLACER.

MINING.—*Placer Herald*, April 24: The Auburn gravel mining and ditch company, we understand, is driving things ahead rapidly. On the new ditch, which is taken out of Bear river ditch, above Clipper gap, to carry water to the claim, there are about 125 Chinamen at work. This ditch is to be three and one-fourth miles in length, beginning as above mentioned and running to top of hill back of Watson's ranch. From this point to the claim, a distance of about two miles, the water will be run through iron pipe 22 inches in diameter. This pipe is to be laid under ground, the ditch for which is also being dug by Chinamen. For fluming on the line of the ditch and fitting up the claim the company, we understand, will use about 100,000 feet of lumber, for furnishing which G. Van Geison, of the Sugar Pine mill, has the contract. The contract for cutting the bed-rock tunnel on the line of the new ditch is let to members of the company, and T. H. Gordon, we are informed, has the contract for placing the pipe on the ground. It will thus be seen that work on all parts is now, or very soon will be commenced; and almost without a doubt the entire work will be completed and the mine opened ready for operation within the prescribed time; viz., July 1st, 1875.

PLUMAS.

PROVIDENCE HILL.—*Plumas National*, April 24: Rush creek has been one of the richest streams ever discovered in Plumas county, and the Providence hill company are making good its high reputation. They took out \$50,000 for their run last season, and the pipes are running on equally good ground this year, but water is short and will not last for a long season's run. Mr. J. T. Serrin is unimpeachable. We are told that this company have more ground than they can work for years to come.

SAN BENITO.

CINNABAR.—*Watsonville Pajaronian*, April 22: T. Beck, J. A. Blackburn, N. Short, Mr. English and Mr. Hunt, have lately made discovery of a valuable quicksilver mine in the Staton mining district, San Benito county. Work already done there indicates a large body of ore, and imperfect assays of the top rock show 25 per cent. quicksilver. The Gray Eagle quicksilver mine looks now like a very good thing.

The Comstock quicksilver mining company, which was mentioned a short time since, seems to be progressing rapidly. We notice in front of Griffin's store four flasks of quicksilver, or about 300 pounds of metal, lately retorted at their mine. A larger force of workmen is soon to be set at work.

SONOMA.

LOCAL ITEMS.—*Russian River Flag*, April 22: The following quicksilver shipments were made from Calistoga last week: California Borax company, 282 flasks; Great Western, 95 flasks; Kearsarge, 5 flasks.

The Oakland mine, on the Hogsback, is doing well with its retorts; 100 flasks of quicksilver were shipped from there through Holsburg within the past week.

The Mt. Jackson furnace, after having had its condensing capacity trebled, was fired up last Friday and is working satisfactorily, without losing any metal. The yield of quicksilver is now from one to one and a half flasks a day.

The Great Eastern is turning out excellent ore in large quantities.

SIERRA.

QUARTZ.—*Mountain Messenger*, April 24: The owners of the Johnson ledge (we don't know its other name) near Rock creek, are now working five men, pushing ahead their lower tunnel. There are good indications that they will not have much further to go. The rock is rich, as demonstrated in the workings above.

BUNKER HILL.—We understand that the Bunker Hill mining company, near Little Grizzly, have found exceedingly good pay in their diggings. Within a space of two sets of timbers they are reported to have taken out thirty ounces, not long since.

ROCKY POINT.—Mr. Pickett, superintendent of the Rocky Point quartz mine, arrived here on Sunday afternoon, and at seven o'clock Monday morning had a gang of men at work in his tunnel. When he left last fall he had just reached the ledge. He will put the tunnel through the ledge as rapidly as possible and will thoroughly develop the mine, of the value of which there now remains no doubt.

WORK.—The Oro mining company will immediately put a force at work in their mine to develop it more fully by following the ledge into the hill. They have about one hundred feet of quartz above where the ledge was tapped, and from the pitch of the ledge on the surface this will increase rapidly as they go back. Bids for constructing a mill and machinery will be opened Saturday, 24th.

TRINITY.

FROM CINNABAR.—*Trinity Journal*, April 24: A friend writes us under date of April 18th, as follows: "Most of the parties here are doing nothing toward prospecting their claims, but Micawher like are waiting for something to

turn up. There is nothing new or exciting here. H. C. Wilt is still getting good prospects in his claim. Worland & Butler got in the first load for their furnace yesterday, which I understand they intend to erect immediately. Lytle & Hawtett are running their retorts, smelting selected ore, and are making two hundred pounds of quicksilver a day; they say they will make five hundred pounds a day as soon as they start in on concentrated ore."

Mr. J. A. Lytle was in town this week and informed us that his firm would commence retorting concentrated ore to-day, and expect henceforth to make from 100 to 150 flasks of quicksilver per month. They have completed three and a half miles of ditch, from Crow creek to their mines, and have their concentrating works running satisfactorily. Mr. Lytle thinks quicksilver can be produced cheaper in this county than elsewhere, owing to the richness of the ore and the facilities for mining, concentrating and reducing.

TUOLUMNE.

A PUBLIC BENEFIT.—*Tuolumne Independent*, April 24: The Tuolumne hydraulic mining company contemplate making extensive repairs of their Hydraulic Ditch in time for next season's water, and work will be commenced without delay. They will start in at the north fork of the Tuolumne river, follow the old line of ditch and convey the water from the river to their reservoirs on Sullivan's creek. The object of the company in making these repairs is to supply the dry season with water until nature herself showers it over the country. About four years ago this ditch was in running order and gave a good supply for mining and irrigating purposes; but this season the ditch is supplied by the reservoirs alone, and not having the usual amount of spring rain, is the cause of the scarcity of water at the present time. When the works are repaired to this river an abundance of water will be supplied from this source. The ditch will furnish the necessary element to Kincaid Flat, Algerine, Poverty Hill, Montezuma and the lower section of the county. In this section it waters Sonora, Union Hill and Shaw's Flat, and so on down through the Rough & Ready section.

THE NEW ALBANY.—Dr. Walker, superintendent of this mine, informs us that they will start in immediately to put on a first class ten-stamp mill, with all the modern improvements. The iron work will be done by the Sonora foundry company, their work being noted as much superior and finer in finish than the San Francisco foundries turn out; besides other advantages in having this work done at home, where alterations, repairs, etc., can be more satisfactorily and cheaply accomplished. The example of the New Albany in patronizing our local mechanics is one we hope to see followed by other companies, as being a benefit not only to themselves but to the locality wherein they expect to find their reward. The mill buildings will be put up as soon as lumber can be obtained. About 20 men will go up next week to prepare roads for hauling the lumber for the flume, which, with the ditch, will extend to two and one-eighth miles above the mill site, to a point on the north fork of the Tuolumne, for furnishing water. Its capacity will be about 250 inches, with a fall of 300 feet at the mill.

The old Summerset mine, owned by Thos. Whitto, Benny Sonlsby, John Sherwood and J. D. Redmond, started up last week. The mine is about a quarter of a mile from the Spring gulch, and it is the intention of the owners, at present, to haul the rock thither for crushing. They have cleaned out the tunnel of this old mine and are engaged in stoping and sinking on the chute, and have come upon rock that will mill as high as \$20 and \$30 to the ton.

Nevada.

WASHOE DISTRICT.

JULIA.—*Gold Hill News*, April 22: There is a slight increase in the flow of water at the bottom of the shaft. The main south drift on the 1000-ft level is still driven vigorously ahead, the face in porphyry, mixed with broken quartz of a little harder character than has been encountered for some time past, although it is still good picking.

OPHRE.—Daily yield, 150 tons of ore, mostly from the ore stopes and breasts on the 1455-ft level. The north drift from the 1600-ft station in the north winze has been extended along the ore vein a distance of 60 feet, at which point a cross drift has been run due east 80 feet and another west 50 feet, the face of both drifts still being in rich ore, and neither having yet reached the walls of the ledge. The east drifts at both the 1500 and 1600-ft stations in the main shaft are being pressed forward to connect with the north winze works, as rapidly as the nature of the work will permit.

CALIFORNIA.—The joint drift on the 1400-ft level is in 215 feet, the face in fair grade ore. The winze from the 1400-ft level is down 58 feet, the bottom still in good ore. The south drift in the ore vein from the winze is in 197 ft, the face in rich ore. The face of cross-cut No. 2 on the 1500-ft level is still in low grade quartz and ore. Cross-cut No. 3 on this level is in 263 ft, and has not yet reached the east ore vein. Cross-cut No. 4 is in a distance of 145 feet, and cross-cut No. 5, 70 ft. The face of the north drift to connect with cross-cut No. 4 is still in rich ore. Enlarging the main north drift on the 1500-ft level is making good progress.

SOUTH CALIFORNIA.—The fine large three compartment working shaft being sunk, is today down about 90 feet, and excellently timbered throughout. The rock at the bottom

is of a porphyrite character, with regular cleavage allowing of very good progress. The ore vein, which lies on the east side of the shaft, is a fine looking species of reddish quartz, giving good assays in silver and gold, and widening out as farther depth is attained.

BELCHER.—Driving the south drift from the bottom of the south winze on the 1500-ft level is making good headway, the face still in ore. Sinking the middle and north winzes below the 1400-ft level is making very fair headway, the bottom of both still in ore. The ore breasts are all looking well throughout the mine, the quality of ore having shown an improvement during the past month. Daily yield 450 tons of ore.

CALEDONIA.—Sinking the new shaft is making fine headway. The new powerful air compressor is on the ground ready for erection, and should the flow of water interfere with the sinking, a six-inch pump will be put in and run until the heavier machinery is ready to start up. A drain tunnel has been started which will tap the new shaft at a depth of 120 feet from the surface, saving that amount of lift for the water.

SAVAGE.—A large new giraffe has been placed in the main incline ready for use. The water tanks at the 2200-ft station are about completed, the car tracks laid on that level, and the new incline machinery ready to put into full working operation, so that it will be but a very short time now before the development of the ore vein on the 2200-ft level can be commenced in good earnest.

CONS. VIRGINIA.—Daily yield, 450 tons of ore. The ore breasts and stopes show no change on either the 1400 or 1500-ft levels. Owing to the repairs being prosecuted at the Gould & Curry shaft, no work is being done on the 1550-ft level. The joint drift on the 1400-ft level has not yet reached the ore vein. The C & C shaft is down 375 ft, at which point large water tanks are being put in to catch the water, which is believed to be only a surface vein. The mills are running up to their full working capacity, and the prospects of the mine are more flattering than ever before.

YELLOW JACKET.—The three new pumps in the main incline were all in position day before yesterday, all working with the greatest perfection. Draining the water from the incline below the 1740-ft level was immediately commenced.

SIEBNA NEVADA.—Sinking the new shaft is making the usual good progress. Sinking the old shaft is also making fine headway. Driving the northeast drift from the 700-ft station of the old shaft to prospect the ore vein and connect with the new shaft for air purposes is making good headway, the face still in a very encouraging character of ledge material.

HALE & NOBSCROSS.—The north drift on the 2100-ft level is in a distance of 331 ft, and will probably connect with the drift from the Savage on the same level in a day or two more, giving a much needed circulation of air, and greatly facilitating the developments on the lower levels in both mines.

SUTRO TUNNEL.—Very good progress has been made until last Monday night, when from lack of requisite timbering quite an extensive cave occurred between the face of the header and shaft No. 2, completely blocking up the tunnel. The men working the header were fortunately warned in time and made their escape. The work of tunneling through this caved mass, "catching it up" by means of spilling driven ahead, is already commenced, and the difficulty will soon be disposed of.

MEXICAN.—The quartz and ore on the northeast drift, on the 1465-ft level, are showing a decided improvement, and the prospects of finding a paying mine are becoming more favorable every day.

BULLION.—The east cross-cut from the north drift on the 1750-ft level of the Imperial is now in 70 ft, and will reach the ore vein in a very short time.

EUROPA.—The face of the drift is now in a solid body of quartz, which is no doubt the main ledge itself, showing bold and strong, but giving no high assays as yet.

LADY BAYAN.—The main west cross-cut on the 250-ft level is in 430 ft, the face still in low grade ore and white quartz of a very favorable character. It is undoubtedly a continuation of the same body found in the south drift, on the level above. Cross-cut No. 3, on the 80-ft level, is still in fine ore.

CHOLLAR-POTOSI.—Daily yield 35 tons of ore, the assay value of which is \$29 per ton. Both the south drift on the 1150 and 1250-ft levels are advancing steadily.

SILVER HILL.—The erection of the new pumping machinery is nearly completed and will undoubtedly all be ready for action by the first of May next. The ore prospects at the third level are looking more favorable.

SEC. GOLD HILL.—The new steam hoisting works have been started up and are now in successful operation.

OVERMAN.—Every possible effort is being made to get the new powerful pumping machinery running at the earliest moment. It is confidently expected that everything will be in readiness to start up by the first of May.

BALTIMORE AND AMERICAN FLAT.—The new pumping machinery is all running and works with the utmost smoothness. The water is being rapidly drained from the shaft. Cross-cutting the ore vein on both the 750 and 850-ft levels in both the Baltimore and American Flat ground will be commenced immediately.

LEO.—The ledge in the face of the main tunnel continues well defined, and carries a very favorable character of vein matter. The cross-

cut from this north drift is now in 20 ft in very promising formation.

IMPERIAL-EMPIRE.—The main south drift on the 2000-ft level is still driven vigorously ahead, the face in clay, quartz and porphyry.

ORIGINAL GOLD HILL.—The ore body developed by the cross-cut and raise of the south drift, is opening out splendidly, showing plenty of good milling ore, which gives very satisfactory assays.

GOULD & CURRY.—The erection of the new powerful pumping engine is making good progress, but will not probably be in readiness to run for a couple of weeks yet.

JUSTICE.—The water continues about the same as at last report. The rock in the face of the south drift at the 800-ft level is a little softer.

PHIL. SHEPIDAN.—The rock in the face of the drift is getting softer, with more streaks of black clay, and the stringers of quartz are coming in smaller and more numerous.

AMAZON.—The new working shaft is down 83 feet and thoroughly timbered throughout. When a depth of 100 feet is attained will be opened and a drift started to cross-cut the ore vein.

UTAH.—The flow of water from the face of the north drift on the 400-ft level, and also that from the bottom of this shaft remain unchanged.

SENATOR.—The south cross-cut has not yet reached the hanging wall of the ledge, but probably will very shortly, when drifting both north and south following the vein matter will be commenced.

MOORE AND MORAN.—Sinking in the shaft is about being resumed, and valuable developments may be looked for, as there are more indications, and really good ore, at the surface of this mine than anywhere along the east range.

NIAOABA.—The ledge at the bottom of the shaft continues to show improvement. Everything is working finely.

CORTEZ DISTRICT.

A SPOILT STORY.—Austin Reville, April 22: Many of our State exchanges, of late, have contained flaming accounts of the big bonanzas recently developed in Cortez district. We never like to spoil a story of a mining strike, but in this instance we have the most reliable information that "the component parts" of the ore in this mine are "principally lead." Indeed, to such an extent has the bonanzas increased in galenaic wealth that it is impossible to mill it, even with reverberatory furnaces, and the mill has been shut down. The Mexican pack train which had been employed in packing the ore from the "bonanza" to the mill, passed through Austin yesterday on its way to Birch creek, where it will be used in the wood business. The "bonanzas" may do smelting, however.

EUREKA DISTRICT.

RICHMOND SMELTING WORKS.—Eureka Sentinel, April 22: Since the closing down of the furnaces of the Richmond company the greatest activity prevails about the premises in repairing the works and introducing new improvements. The three old furnaces are being thoroughly overhauled, and when again brought in use will be in better condition than for a year past. The new iron furnace, designed for coke burning, now in course of erection, will be completed in a short time, and should the experiment in using this style of furnace prove successful it will doubtless produce an innovation in the art of smelting the ore from the mines of the district.

The wooden fine of the fume arrester, which has afforded us so many items, is also being attended to; the wooden portion is being torn away and is to be replaced by iron, which will prove more serviceable than its predecessor, which was continually catching fire and delaying the progress of the work. Superintendent Rickard is indefatigable in his efforts to have work resumed as soon as possible, and hopes to have everything again in motion the first of next month. The refining works of the company continue in active operation in the crystallization of the bullion to pure metal. Immense cakes of bullion, weighing ten tons each, are to be seen about the building in the various stages of transformation preparatory to the cupellation process. The second set of crystallizers are at work, and the third will soon be erected. The management feel highly gratified at the success attending the working results of this new department, as it insures them far better returns on their gross bullion than formerly, when compelled to pay the various charges incident to the transportation to the refinery in New York.

PEAVINE DISTRICT.

THE MINES.—Nevada State Journal, April 22: All of the mining companies are actively pushing ahead work. The different ore breasts in the Consolidated Poe are all looking well, and ore is constantly being hoisted for the mill. The ground for the new hoisting machinery is all graded. Breking through the large shaft on the Golden Fleece to the surface is getting along finely. Their machinery will consist of a double-acting engine, pump, etc., and will soon be on hand, to be erected on this shaft; then the incline will be sunk down about 500 ft further, when the most valuable ore will be taken out. Sinking the shaft of the Mineral Chief progresses; several feeders of quartz have been struck in descending the shaft. Water is coming in just in the direction the ledge pitches. The Carr tunnel is in a distance of 280 feet, and a contract has been let for another 100 ft. The Mountain View company have a fine 6 ft ledge,

much of which is high grade ore, assaying up into the hundreds. Work is being vigorously prosecuted on this claim. They are now on their ledge a distance of 40 ft, and will commence shipping their high grade ore in a few days. The New York tunnel is in 500 feet.

WHITE PINE DISTRICT.

RICH ROCK.—White Pine News, April 24: Uncle Johnny McCann has shown us some very rich specimens of ore, taken from the Bowie & Brown mine, situated on Blaine Hill, only about half a mile from Hamilton. The ledge is three feet wide, and has well defined walls. Some ore from this mine was worked at the Smoky mill two or three years ago which averaged \$129 per ton. It is considered a good mine.

LOOKING WELL.—The Summit tunnel company are running their tunnel on the east side of White Pine mountain, and are progressing finely. Their prospects are very flattering, having recently struck a body of ore which assays beyond the expectations of its owners.

SILVERADO MINE.—This mine is situated at Silverado canon, in this county, and is astonishing its owners with its wonderful yield. It has long been a paying mine, but recently, at a depth of 250 ft, they have struck a four foot ledge with well defined walls, and good judges estimate that the ore will not go less than \$200 per ton in silver alone. Mr. Shoenbar, the owner of the mine, is now engaged in sinking an artesian well at that place, with a view of putting up a furnace, if he can get a sufficient supply of water to run it.

Arizona.

SALE OF QUARTZ.—Arizona Citizen, April 16: Mr. S. Frederick purchased of Jack Goodwin, on Monday last, one-quarter interest in 2400 ft of the Senator ledge for the snug little sum of \$10,000 cash. This is none of your bonding nonsense, but an up and up sale and the money paid. The best of it is, Mr. Frederick being already largely interested in the ledge, and having worked the rock for a long time, knows just what he has bought, and would not to-day take twice the amount for his bargain.

MOHAVE COUNTY.—By telegraph, April 24: Late advices from Mohave county say the mines are looking better daily. Many strangers are arriving from California every day. Mineral Park presents a lively appearance. Quick-silver has been discovered in abundance in the valley of Chlorido, and experts pronounce the prospects very flattering.

Colorado.

GEORGETOWN BULLION SHIPMENTS.—Colorado Miner, April 10: The silver reducing company shipped for the week ending April 9th, \$7,735. The Judd and Crosby shipped for the same period, \$5,951.

BURLEIGH TUNNEL.—The Burleigh tunnel is being continuously worked, under the superintendence of Mr. C. G. Ryder. The length of the tunnel is now 1825 feet. The heading is very hard rock, and the average distance made per month is 20 feet. At present the only work being done is that of pushing the tunnel forward, no drifting being done on the lodes crossed by it.

DEMOCRAT MOUNTAIN, CLEAR CREEK COUNTY. There is no let up to the amount of work being done, and the growing productiveness of the rich mines on this mountain. Large amounts of ore are being daily extracted from the Rogers, Polar Star, Queen of the West, A. T. Stewart and other noted mines.

THE DOUGLAS TUNNEL.—Mr. Goetzel has been steadily driving the tunnel, owned by the Douglas silver mining company, into the heart of Douglas mountain, until it has reached a distance of 675 feet. Mr. Lamphire has thoroughly examined the ground into which this tunnel is running, as well as the character of the veins crossed, and believes the property to be one of the most promising in the mountains. The mountain shows no disturbance, the lodes are true fissure veins, and the development in lode No. 1 gives the most encouraging results. Mr. Goetzel deserves great credit for the energy he has displayed in driving this great enterprise, and every one will rejoice that a brilliant success is about to crown his efforts. He has had faith in Douglas mountain, and in tunnels, and has never doubted the result.

BROADWAY TUNNEL.—The work of development in this fine property, which has recently been started up after a long period of inactivity, may now be said to have merged into productive work. Rich ore and considerable of it has recently been struck, and we expect soon to be able to give a report from it.

Utah.

CLIFTON DISTRICT.—Correspondence Salt Lake Tribune, April 21: The Deep Creek Consolidated company have resumed operations, and are repairing their furnaces and putting men to work on their mines.

It is the opinion of every one who has visited this district, that it must ultimately become one of the most important in the Territory. Our great need is cheap transportation. Owing to our great distance from Salt Lake and the railroad, we pay a double tax on supplies and bullion, so that low grade ore will not pay to handle. It is the experience of all miners that the abundance of low grade ore is what makes a camp.

Clifton district is fortunate in having ore of a grade that will pay. Iron and copper abounds, but has been neglected owing to the great expense attending the hauling. The Deep Creek company, in working one of their mines on Gold hill, came on a splendid body of copper, four feet thick, and have shipped

two car loads to Baltimore, as an experiment, the result of which I will be able to inform you of in my next.

This great expense and difficulty of lining furnaces would be obviated if a railroad were here, as we have quarries of fine rock of a quality superior to any known on this coast, and in unlimited quantities.

Iron of a quality admirably adapted for fluxing ores is found here. Saving the comparatively small quantity used at the furnaces of this district, it has not been touched.

General News Items.

A young German, while seated in Portsmouth square, one day last week, took a derring from his pocket and applying the muzzle to his breast, deliberately pulled the trigger. Much to the Teuton's disappointment, the wound resulting did not prove immediately fatal, and he found himself obliged to hear what the public thought of his suicidal attempt and the cause leading thereto, as expressed in a note found in his pocket.

Two employment agents in Virginia were arrested last week for swindling immigrants out of a few dollars, under the pretence of furnishing them employment. The swindlers were adjudged guilty on seven distinct charges, and on the first fined each \$200 and in default of payment imprisoned for 90 days.

A LATE London dispatch states that considerable excitement prevails in Athens over the approaching elections, and that a state of siege is reported as impending. The Government is concentrating 5,000 soldiers in Athens, and it is supposed it intends to raise the army to a war footing.

CHARLES E. PICKETT, of this city, has been released from confinement in the county jail, where he has been since August last, under a sentence for alleged contempt of court. Mr. Justice Crockett was the court for which the philosopher expressed his contempt.

The steamer *Ventura* of G. N. & P. line was lost off Point Sur on the night of April 20th. Over 100 passengers were aboard, but all reached the shore safely. The loss, uninsured, is estimated at \$150,000.

THREE steamboats were burned at New Orleans on the 23d inst., and it is reported that 100 persons lost their lives by drowning while attempting to escape from the flames.

AN Oregon paper tells of a deaf mute who came into its composing room one morning and committed to memory all the boxes of the capital and lower cases, and set 1500 ems during the day.

A CHANCE has been made in the C. P. R. R. time table. Overland trains leave at 8 instead of 7 A. M., as heretofore, and arrive at 5:35, instead of 8:10 P. M.

The tannery of John F. Shultz, at Ora Leva, near Forbestown, in Butte county, was completely destroyed by fire on the night of the 19th inst.

A BANQUET was given to Carl Schurz by a large number of distinguished citizens in New York last Thursday evening. The ex-Senator is about to sail for Europe.

The old foundry building in Sacramento, belonging to the C. P. R. R., was burned last Saturday night.

A CAR attached to a train on the N. P. R. R. was blown from the track near Sancelito last week, and rolled down an embankment.

ATTORNEY General Williams has resigned and Judge Pierrepont, of New York, is reported to have been tendered the office.

It is said that \$100,000 worth of cattle and horses have been killed by buffalo gnats in Tennessee within the last week.

Industrial Items.

THE West Coast manufacturing company has 250 men at work, fifteen hours per day, turning out the furniture for the Palace Hotel, which the contract requires to be finished by the first of July. The order amounts to over half a million dollars.

A COMPANY has been organized in Los Angeles to bore for petroleum on the lands of a Mr. Boushay, near the city. The indications of oil are said to be quite favorable.

The Los Angeles Express expects General Forrest, of Memphis, Tennessee, to reach that place in May with 1,000 immigrants, more or less.

THE Grangers' Business Association of Dixon filed articles of incorporation with the Secretary of the State.

SIXTY men are at work on the new road between Santa Rosa and Napa, and expect to complete it in about thirty days.

GILROY presents, in the estimation of the *Leader*, great advantages for the erection of a tannery.

TRACK laying commenced on the Walla Walla Valley railroad on the 12th instant.

A MANUFACTURING city is what the Amador Ledge would have lone city become.

WAREHOUSES are to be erected and a wharf constructed by the Grangers at Martinez.

THE Petaluma woolen mill is nearly completed.

A new brick yard has been started in Chico.

Hydrographic Surveying.

The following paper was read before the California Academy of Sciences at its last meeting, by T. J. Lowry, of the U. S. Coast Survey:

Hydrographic surveys of bays, lakes, rivers, gulfs and the parts of oceans adjacent to coasts are indispensable requisites to a safe navigation and hence successful international commerce. Being of national importance they are therefore national undertakings—and the Government Coast Surveys and navies of all countries are engaged in determining and mapping the topography of the water basins and channels of the earth.

An accurate survey of waters adjacent to land is based upon a survey of the adjoining lands by means of which the figure of the coast and the positions of a sufficient number of conspicuous and well defined objects near the coast have been ascertained. These objects are the landmarks by observations of which the positions of points on the surface of the water (and hence the soundings) are determined. The relative positions of the landmarks are ascertained with a degree of accuracy proportionate to the character and extent of information to be given by the chart. When perfect accuracy is aimed at, many stations on shore (and especially on island shoals and reefs) are first determined usually by a trigonometrical survey whose accuracy is tested by a base of verification. The stations in the triangulation being selected with reference to the ultimate ends in view (viz., the wants of the hydrographer and navigator), will be so chosen as to include or determine lighthouses, headlands and other remarkable objects—not allowing the triangles, however, to depart too much from the well conditioned forms. In making choice of stations, and thus giving shapes to the triangles it is well to remember that where all the angles are to be observed, the condition most favorable to the accuracy of computation—i. e. where instrumental errors and errors of observation will least affect the determination—is where each triangle is equilateral. But where two angles only are to be observed, the unobserved angle should be a right angle and the observed angles equal to each other and never less than 25 or 30 degrees. Experience proves that in well conditioned triangles the small errors made in the measurement of the angles do not accumulate through each successive step in the operation, but on the whole tend to compensate each other.

Whatever extent of coast may be surveyed, each series of hydrographic operations will be confined to comparatively limited spaces, and the whole will consist of numerous detailed charts correctly linked together and harmonized by means of the triangulation on shore, a description, therefore, of the *modus operandi* in making a hydrographic survey of a single harbor or short sea reach will apply equally to the system adopted in the survey of an extensive line of coast.

Having made a reconnaissance of the region to be surveyed and gathered a general idea of the facilities for, as well as the difficulties of doing the work, the next step is to locate tide gauges and tide observers.

Judging from all information that can be gathered of the prevailing winds, currents, tides, shoals and the configuration of the shore line the hydrographer will fix the number and sites of his tide gauges so as to get data in determining the figure of the surface of the water at any given instant. They should be more numerous the more the surface of the water at any instant deviates from the horizontal form. And the fewer the gauges used the greater the care to be exercised in deciding upon their locations. Placing a gauge within a bar, sand-bank or other impediment to the free action of the water, or within a lagoon which winds fill with water faster than it can escape, is to be especially guarded against. And in comparatively limited basins of water at least two gauges should be established—one at that side of the basin nearest "whence the prevailing winds come" and the other nearest "whither they go." These gauges are not only checks on each other when the wind's action is an insignificant element, but where the wind drives water from one portion of the basin and piles it up in another, they furnish data indispensable for harmonizing soundings taken on those and calmer days.

In such a basin, when but one gauge is used, the proper place for it, theoretically speaking, is the center of the basin. These considerations attended to, each gauge is firmly fixed in a well sheltered spot, so that its zero shall be below low-water at neap, and its top above high-water at spring-tides. By proper circumspection for the site of each gauge, one will generally be found to answer for each station, but where the observations are made from shore two or more may at times become necessary—the observer following the tide from gauge to gauge as it goes out and retreating over the same path as it comes in. The kinds of tide gauges are as various as the circumstances demanding them. The one ordinarily used is of the simplest kind, a straight vertical post divided into feet and tenths, numbered from the bottom upwards; this is found generally to serve its purpose, inasmuch as when it is too windy to read the gauge correctly, it is blowing too much to sound accurately. A vertical tube with small holes at the bottom to admit the water which supports a float, is however, susceptible of closer readings under all circumstances; and for getting off-shore tides, Mitchell's gauge is admirably adapted; while as a self registering

gauge, Saxton's stands without a parallel and leaves nothing to be desired.

The zero of each gauge should be referred by means of a spirit-level, or otherwise, to a bench mark cut distinctly and durably on some permanent object (and the remark made in the book) so that if displaced it can be properly replaced in position.

For the purpose of reducing the soundings it is mainly essential that the tide-gauge, and sounding-boat watches be together; but where the laws of the tides of the locality are also desired, it is best to keep either lunar or mean solar time. A series of observations of the tides on these gauges made simultaneously with the soundings furnish data for reducing each sounding to the reference plane—the mean of the lowest water. This plane is also given by these tidal observations. The frequency of the necessary readings of the gauge varies from every half-hour to every five minutes, according to the rapidity of the rise and fall of the tide.

And now, if there be not on the shore permanent well-defined objects that will serve as signals, such as spires, towers, flagstuffs, light-houses, or tall slender trees fixed by triangulation, then the hydrographer erects the necessary signals; usually tripods boarded up, and painted white if projected on dark background from the sounding boat, or red, (or black) if against the sky or a sandy background.

The tide-gauges and signals being erected, the next step is to determine carefully with a theodolite the relative position of these signals and plot them by the computed sides of the triangles of which they are the vertices. It is, however, not imperative that the actual sizes of the triangles be at first known—but the triangles can be computed and plotted from any assumed base, since the "relative positions of the signals" is the essential desideratum.

Hydrographic surveys all have for their main object the tracing, determining and plotting, on a suitable scale, the contour lines of navigable channels and water-basins. Contouring represents the inequalities of the earth's surface by determining the relative heights of any number of points above or below a line equidistant at every point from the earth's center. This line is what is understood by the term "a level-line"—and is that which is assumed by the surface of the water when at rest. In mapping the contours of parts of the earth not covered with water, after the principal contour lines are drawn on the topographical sheet, intermediate lines may, with the ground before the eye, be sketched in; but such interpolations are obviously impossible when tracing the contour lines of a basin filled with water, as in hydrography, where a series of points in the curves of equal depths are brought out only by lines of levels made with the sounding-line. Now since these lines of equal depths are analogous to contour-lines on land—being contour-lines of the bottom of the water-basin drawn through those points where the reduced soundings are equal—the same rule hence, obtains in hydrography as in topography for the directions of the lines of levels for developing them—viz: the perpendicular and parallel to the strike or dip of the bottom, i. e. one system of sounding-lines coincident with, and another at right angles to the lines of the steepest declivity of the bottom. The lines, run in the general directions of the "curves of equal depths, or horizontal curves, are the main-lines in developing the contours of the bottom, yet the auxiliary lines which should be run perpendicular to these not only check these depths but also furnish additional data for drawing these curves of equal depths. At a crossing of these lines the difference of the soundings should not be more than three per cent., and the limit of error must not exceed five per cent. of the depth.

To form an idea of the general configuration of the bottom of a body of water, we must call in every available aid; as, the topography and geology of the adjacent coast, the effects of currents, tides and prevailing winds, and most of all the revelations of our lead-line, which assist us in judging of the topography of the parts yet unsounded, and hence better fix upon the directions of the lines to be run. The force and directions of winds and currents and qualities of the vessel must of course be considered in laying out directions of sounding lines. And the greater discretion exercised in giving directions to these lines the fewer in number will it require to bring out the bottom's varied features in the length and breadth of their modulation. The number of lines required depends upon the extent of the information to be furnished by the chart.

If, for purposes of general navigation, the soundings on the map will be sufficiently numerous when the horizontal curves (viz.—fathom and half fathom, up to three fathoms and inside of that feet, curves) can be drawn without doubt as to their directions in any case. As to the frequency of the casts, where the bottom is very irregular, are wanted not casts at studiously regular intervals, but every possible sounding.

Whether it is the demands of the navigator or the marine engineer that are being satisfied, along with these contour lines of the bottom are required the materials of which the bottom consists, the level, rise and fall of the water, the directions and speeds of its currents and at times the temperatures and specific gravities of the water. The accuracy of the methods and instruments for executing these surveys also varies with the amount of detailed information required. If the survey be made for the erection of a breakwater instead of purposes of general navigation, then are de-

sired more instruments for observations, more well determined signals, more cast positions determined, more soundings on a line and more lines of soundings, more specimens of bottom and more current observations. In every case, however, the whole ground should be gone over thoroughly to bring out the general features of the bottom and detect each sudden irregularity of depth, which should be traced through its every line of approach, and if it proves to be an isolated knoll or ridge, it may be "rayed off" by planting one or more temporary buoys on it, and to and from them running radii in different directions. However, as these radial lines are often insufficient to bring out its every feature, others may be run at right angles to them. Yet for general purposes of navigation the general features and extent of a reef and the shoalest cast on it are found amply sufficient. As each sounding is taken the surveyor notes its depth and also the time which fixes its position with reference to other points on the line determined by either sextant, theodolite or compass angles on known fixed points.

The degree of precision with which the positions of the sounding boat are fixed determines the accuracy, and hence usefulness, of a hydrographic survey. To fix the position of the sounding boat under every variety of circumstances is therefore the all important problem in practical hydrography, and the methods most universally relied upon by the hydrographer for determining his boat's position is that by the three-point problem.

This problem is wide in its application, accurate in its determinations and most simple in its graphic solutions. The simultaneous observation of the two angles subtended by three signals fix the place of observation under every possible contingency—except when it is on the circle passing through these three signals—i. e., when the three circles of position are coincident. The accuracy of the determination of positions by this problem depends mainly upon the relative positions of the signals and the observer, and the size of the observed angles—being the very best where the signals are equidistant from the observer, and subtending angles of 120 degrees. The three signals in a straight line, is a favorite location with many hydrographers, as it offers but one case of indeterminateness, and that very easily avoided, of being on the straight line passing through them. But in general a most desirable location is where the circle through the three signals is convex towards the observer, and the middle one is the nearest of the signals, for then "a revolver" is impossible. Other things being equal, it is better to "angle on" the more distant objects which subtend good sized angles, say from 45 to 135 degrees, for not only is the parallax of the sextant then less, but an error made in getting an exact coincidence of the images of the signals is then less felt by the angles than if the signals were near or the angles very acute.

And besides what is thus told by the relative positions of the signals, the hydrographer should be able to read the tale which the size of the observed angles tell of a position's fixedness. If the sum of the observed angles equals 180 degrees or more, then the observer is sure he is not on the circle of indeterminateness. But if this sum is less than 180 degrees and equal, or nearly so, to the supplement of the angle subtended at the middle signal of the other two, then the position is not determined. By having these supplements written about the signals, between the proper lines, on the field-sheet, we can by a mental summing of the observed angles tell (without plotting) whether we are too near the circle to get a good determination; and may thus catch other angles that better fix our position.

The three-point problem finds in the three-arm circular protractor an accurate, simple and most expeditious graphic solution, which is most extensively used in plotting positions of the sounding boat. In practice the observed angles are set off on the proper lines of the protractor, and the fiducial edges of its arms caused to traverse the three points representing the signals observed upon, and the center dotted and the position is plotted. If breakers denoting danger be observed at a time when it is impossible to anchor over them or even approach them to fix a buoy to mark their locality, their position may be marked quite accurately by pulling around them and getting cross ranges (or cross magnetic bearings) of prominent objects on shore so disposed as to guide the observer to the spot in more favorable weather, when a perfect calm may leave no trace whereby the danger can be recognized.

A NEW MODE OF MANUFACTURING SCREWS has been introduced at Edinburgh. By this method the screw, instead of being made, as at present, by cutting away the iron of the bolt to leave the thread, is formed by rolling the screw on the bolt blank while hot. It is claimed for this process that a great saving of time and labor is effected. Recent experiments have shown that the tensile strength and the holding power in both hard and soft wood of rolled screws were considerably greater than those of cut ones.

VENTILATION.—The importance of a thorough ventilation in our dwellings may be inferred from the following: If the air of a crowded apartment is conducted through water, so much animal matter is collected in the water as to occasion a speedy putrefactive fermentation, with a disgusting odor.

The Locomotive.

Looking at the locomotive in a national point of view, its value to a nation as a machine connected with the development of its wealth and progress is measured by the cost of carrying a ton of goods and a passenger a mile. The lower this can be made, the greater its benefit, and the more extended the range of its influence and operations. This should be the point of strife between nations: how low can you bring the cost of carrying? Any intelligent person who will examine this matter, with the vast amount of data at his command, will find that, considering the price we pay for labor, metals and fuel, no other country has solved this problem with the same gratifying results.

The vast business of the Pennsylvania Railroad, including the passage of the Allegheny Mountains, for 1874, shows that it moved nearly ten millions of tons of minerals and merchandise at a cost of 0.719 of a cent per ton per mile and carried more than six millions of passengers at a cost of 1.60 cents per passenger per mile. Can any other road in the world out of the United States show such results, or anything near them, after equating the prices paid for labor and metals, to say nothing of the severe climate, the steep grades and the sharp curves of this railway, which cannot be encountered without extra cost.

CONVERSION OF LOCOMOTIVES INTO STATIONARY ENGINES AND BOILERS.—The change of gauge on the Great Western Railway, in England, has necessitated the introduction of new locomotives, adapted to the narrow gauge-line now in use, and the locomotives formerly used have consequently been thrown out of employment. These last named engines have been purchased by Mr. Barton, of London, who is converting them into stationary engines and boilers which are likely to be of great service for wind-mill, pumping, and other similar purposes. The boilers are well adapted for stationary purposes, and present several other obvious advantages over the old Cornish type. They evaporate considerably more water per pound of fuel on account of the large heating surface; they have large copper fire boxes; quality of fuel is not so important, as an artificial draft can be created by steam jet in chimney, and can be worked at 120 lbs. pressure, and up to 400 H. P., smaller sizes can be supplied. The engines can be secured on cast iron bedplate if required, are easily moved and occupy but little space. The expense of setting is avoided, as no brickwork or brick chimney is necessary. No doubt also the cost of the converted locomotives is moderate, and as they are at once compact, and massive, and built in a style very superior to that of ordinary stationary engines, it may be of service to our readers, even in this country, to call attention to the above facts.

MASSACHUSETTS MINES.—The Boston Advertiser, which devotes a column and a half to divers and sundry "loaves," "claims" and companies in connection with the Essex mining region, says: "Every item that finds its way from the latest known mining section of New England into the moving stream of news, points to an immigration to the regions near Newburyport during the coming spring and summer as odd and great in proportion as that which inspired Bret Harte's lecture. Yet even at this early period in the undeveloped history of the Newburyport mines, there are many indications of the swindles that will be, of the money that will be lost through speculation in worthless land or by the sudden death of bogus stock companies, and of the chicanery and deception, the levers by which adventurers move their measures. It certainly does not seem as if there could be any possible doubt but what underlying the land for many miles in and around Newburyport are mineral deposits, rich in silver, lead and gold. Outcroppings and undoubtedly genuine specimens of galena, rich in a percentage of silver, have been found in many different places throughout that section that would indicate veins of different length and direction—a sort of titles to the chapters of Essex mining—that are inevitably to follow.

SHEET METAL STATUARY.—The manufacture of sheet metal statuary for ornamental and architectural purposes is quite novel, but fast becoming an important branch of industry. Sheet zinc is the material employed, and it is wonderful to notice the skill displayed in this line, and the perfection to which such work has been carried. The new court-house at Jackson, Mich., has recently been ornamented with a full length figure of Justice, seven feet high, made from sheet zinc, which weighs only 100 pounds. The figure is pronounced by experts as very superior, and was the work of the Kittridge Cornice and Ornament Company, of Philadelphia. This company propose to make a specialty of sheet metal statuary.

SIMPLE TEST FOR LUBRICATING OILS.—The following simple method for testing the products of hydrocarbons or mineral oils in lubricating mediums will be found both convenient and useful for every engineer or mechanic: Fill a bottle with the oil in question, moistening the cork and inside of the neck of the bottle, and then twisting the cork about its longer axis. The best lubricating oils produce no sound, but the more the oil is adulterated with hydrocarbons and products of dry distillation, the louder the noise produced. An oil that gives a loud cry is most unfitted for a lubricator.

USEFUL INFORMATION.

The White Streak in Silk—An Interesting Discovery.

For a number of years the silk manufacturers of this country have been troubled by the appearance of what is commonly called a "white streak" in dyed silk. This name describes the appearance about as well as any other term we can apply, and has been adopted for lack of any more positive information respecting it. It makes its appearance principally on black silk after it has been wound on the spools ready for use on the sewing machines. It is not, however, confined to black machine twist, but is visible in many of the other dark colors.

It has the appearance of a slight roughness or fuzz on the side of the thread as it lies on the spool. It is invariably white and easily recognized, especially when it occurs in the black silk. The combined talents of the silk manufacturers and dyers in this country have been employed during the last few years to discover some method of overcoming the white streak, either by varying the process of manufacture or by covering it in the dye. As yet all efforts have failed to be completely successful. Various theories have been proposed to account for its appearance; much time and money have been spent in the study of the question, without arriving at any certain knowledge concerning it.

Some manufacturers believe that it is due to carelessness during the process of dyeing; that the silk is not thoroughly washed from the soap suds in which it is boiled, leaving particles of soap adhering to the silk. Others stoutly affirm that it is due to the dead wood which the silk takes on as it passes over the wooden rollers of a machine known as the stretcher.

The Nonotuck silk company's present theory is that the streak is due in some way to the process of adulteration to which the silk is subjected as it is wound on to the reel from the cocoon. They think it possible that the cocoons when wound may be soaked in warm water to which a quantity of rice starch has been added, thus making a kind of rice water or thin paste, which the silk takes up as it is wound, thus adding a cheap weighting material to the silk.

That this theory does not account for the appearance of the streak is evident, since some of our brands of silk, we are confident, are perfectly free from any adulteration, but yet the streak occurs abundantly in them. A careful examination with the microscope and chemical reagents, for the purpose of obtaining some definite idea of its nature, soon settled the fact that it is a vegetable substance of some kind; but exactly of what nature, I was unable at once to determine. This slight clue enabled our dyer to apply a dye that would partly cover it. This new process of dyeing, however, was attended with many objections. It was more expensive, while it took a much longer time to dye the silk. Our greatest objection to this method of dyeing was that it increased the weight of the silk with the dye stuff, thus injuring its quality and affecting its strength. We could ill afford to sacrifice the strength of the silk for the sake of covering the streak, so we sought to avoid the difficulty by using another brand of silk. I finally became convinced by careful examination that it was of the nature of a parasite, or a fungus growth on the raw silk. All of my researches tended to confirm this theory.

I have lately submitted samples of the streak, which were found both in the raw silk and in dyed silk, to Professors Verrill, Eaton and Johnson, of Yale College, New Haven, who all confirmed the theory of its being a fungus growth on the silk. An eminent naturalist of Boston, whom I consulted on the subject, also confirms the theory, and thinks that we may find that this growth is connected with the disease with which the silk worms of Europe have been troubled for so long a time.—C. A. Burt, Oneida Circular.

Interesting Experiments With Flowers.

The *Journal d'Horticulture de France* contains some interesting particulars on the artificial coloring of natural flowers. Those that have a violet hue will gradually change color and turn to green under the influence of the smoke of a cigar. This change is owing to the ammonia contained in tobacco. Starting from this circumstance the Italian professor, L. Gabba, has made a series of experiments on a variety of plants with that alkali in its natural state. His apparatus is a very simple one, merely consisting of a plate into which he pours liquid ammonia, covering it afterwards with a reversed glass funnel. The flower to be tested is inserted into the tube. In this way he has seen violet, blue, and purple turn to bright green; intense carmine red (of the pink) become black; white turn yellow, &c. The most extraordinary results were afforded by variegated flowers. When the latter, immediately after this exposure, are dipped into pure water, they will retain their new colors for several hours, after which they simply return to their former state. Another curious discovery of Professor Gabba's is that the flowers of aster, or starwort, that are violet and have no smell, acquire a delightful fragrance and turn red under the influence of ammonia. We know that the Japanese, by means of injections which they keep secret, can color or whiten flowers and obtain wonderful variegation. The Chinese

have also secrets of their own, among which is one for reducing large trees to a dwarf size. The Garden of Acclimatization has at this moment an orange tree, a hundred years old, and imported from China, no bigger than a rose tree; its fruit scarcely attains the size of a cherry.

[The above experiments may be easily repeated by any person curious in each thing. The effect of a black pink or a green violet in a bouquet would certainly be very curious if nothing more.—Ems. Press.]

COLOR OF THE CHAMELEON.—An English paper gives some interesting facts relative to the cause of change of color in the chameleon, which have been gathered from remarks made on this subject by M. Paul Bert, at a late meeting of the Société de Biologie de Paris. This animal, whose natural color is dark green, has the power of changing to pale green, and very pale yellow, this change of color being entirely due to the nervous system. The explanation of this phenomenon is thus given: "Under the skin, and communicating with it, are vessels filled with pigment, coursing through little canals which intersect, cross, and interlace each other in all directions at the back of the epidermis itself. This pigment is afterwards drawn back into the vesicles by the volition of the animal, and the chameleon then takes on a pale tint produced by a pale yellow tissue, visible by its transparency." It has been discovered that the color of the animal is affected by light, and that if disturbed at night the side on which a light is thrown becomes pale, the other side remaining unchanged. So far, no explanation of this curious fact has been suggested, and it offers a field for research and observation which may lead to very important results.

JELLY FROM OLD BOOTS.—The reader may stare, but science smiles supreme, and asserts very emphatically that a toothsome delicacy can be made from a dilapidated foot covering. Some time ago, says the *Scientific American*, Dr. Van der Weyde, regaled some friends not merely with boot jelly, but with shirt coffee; and the repast was pronounced by all partakers excellent. The doctor tells us that he made the jelly by first cleaning the boot and subsequently boiling it with soda under a pressure of about two atmospheres. The tannic acid in the leather combined with salt, made tannate of soda and the gelatine rose to the top, whence it was removed and dried. From this last, with suitable flavoring material, the jelly was readily concocted. The shirt coffee, incidentally mentioned above, was sweetened with cuff and collar sugar, both coffee and sugar being produced in the same way. The linen (after, of course, washing,) was treated with nitric acid, which acting on the lignite contained in the fibre, produced glucose, or grape sugar. This, roasted, made an excellent imitation coffee, which an addition of unroasted glucose readily sweetened.

GOOD HEALTH.

Worth Knowing, if True.

Among the many sanitary virtues which have been ascribed to the eucalyptus or Australian gum tree, we have now the assertion that it is especially valuable for rheumatism, a disease which has heretofore baffled medical science. Instances are given in proof of the assertion, and among others the two following by the *Petaluma Argus*. It appears a gentleman named John Quinlan had tried most of the approved remedies to mitigate the pain of this affliction, without avail. He visited the West India islands and many other regions for relief, but did not obtain it. Coming to Petaluma, one of our hotel keepers, with whom Mr. Quinlan was acquainted, noticed among his guests a man who had his arms and legs bound up with leaves. Upon questioning the party he learned that he was afflicted with rheumatism, and that he had bound the diseased parts with the leaves of the eucalyptus tree, from which he had experienced great relief and apparently almost a permanent cure in a few days. This intelligence was communicated to Mr. Quinlan, who immediately tried the experiment, with the most gratifying results. He procured a quantity of rank green eucalyptus leaves and beating each one slightly, bound them upon the parts in which he felt the most pain. The effect was marvellous; the pain ceased in a short time, and in a little while the long suffering patient felt like a new man. He continued to apply the leaves and to wear them while walking about the streets, and at the end of two weeks felt entirely well. He says no amount of money would purchase from him the power of applying this remedy, should he be attacked again.

The *Call*, of this city, a few days after publishing the above, gave its readers the following additional confirmation: Since our article of Tuesday, attesting to the virtues of eucalyptus leaves in the cure of rheumatism several persons have since called at our office—among the number a clergyman—to corroborate the statement. They report that they have seen the leaves applied to the affected parts of several sufferers from this painful disease, in each of which the relief afforded was almost immediate, with the prospect of being permanent.

This remedy has the merit of being inexpensive. Persons afflicted with the rheumatism may give it a trial. If it will do for others what Mr. Quinlan says it has done for him, a discovery is made for which tens of thousands of suffering people will feel thankful.

Pathological—What we Breathe.

Very suggestive experiments have been made by Mr. Blackly, in connection with his researches upon the "hay fever," with a view of determining the extent to which pollen of various plants is diffused throughout the atmosphere. His first series of inquiries was instituted in a meadow at the average breathing level of four feet nine inches from the ground, beginning in April and continuing until the end of July. A slip of glass was exposed horizontally, coated with a thin layer of non-drying liquid. The results were tabulated daily, and the highest number of pollen grains obtained on a square centimeter in twenty-four hours was 880, June 28. Sudden diminutions in the quantity of pollen—when these occurred in the ascending scale, between May 28 and June 28—were invariably due to a fall of rain, or to this and a fall in the temperature. Mr. Blackly also examined the amount of pollen to be found in the highest strata of the atmosphere. This was done by means of a kite, which, by being attached to other kites, sometimes attained an elevation of 1,000 feet. The pollen was found to be much more largely present at the upper levels than at the "breathing level." Taking the average of the quantities where pollen was present at both levels, he found that while the average of the ordinary level was 21 only, for each experiment, that for the higher levels was 472.33, or more than nineteen times as much. After making due allowance for the difference in the velocity of the air at various altitudes there still remains a great preponderance unaccounted for in the amount of pollen in the upper strata.

Mr. Blackly remarks that his experiments also afforded abundant proof of the presence of fungoid spores in the air in large quantities. In one experiment, which lasted four hours, and in which the number of pollen grains collected at an altitude of 1,000 feet was 1,200, the spores of a cryptogam (probably *Ustilago segetum*) were so numerous that he could not count them. At a rough estimate they could not be less than thirty to forty thousand to the square inch. A fact like this makes the ubiquity of fungoid organisms a thing easy to comprehend.

Delicate People.

There is a constant sympathy expressed by robust people for those of slight physical constitutions. We think the sympathy ought to turn in the opposite direction. It is the delicate people who escape the most fearful disorders, and in three cases out of four live the longest. Those of gigantic stature are almost always reckless of health.

They say, "Nothing hurts me," and so they stand in drafts, and go into the night air to cool off, and eat crabs at midnight, and doff their flannels in April, and get their feet wet. But delicate people are shy of peril. They know that disease has been fishing for them for twenty years, and they keep away from the hook. No trout can be caught if he sees the shadow of the sportsman on the hook. These people whom everybody expects to die, live on most tenaciously. We know of a young lady who evidently married a wealthy man of eighty-five years on the ground that he was very delicate, and with reference to her one-third. But the aged invalid is so careful of his health, and the young wife so careless of hers, that it is now uncertain whether she will inherit his storehouses, or he will inherit her wedding rings. Health and longevity depend more upon caution and intelligent management of one's self than upon original physical outfit.—*Exchange*.

HYGIENIC BOOT SOLES.—Is there any method of making the bottoms of boots so moisture will not pass through them? This is a practical question—several methods have been tried. One is to have a cork layer between the inner and outer sole; but this thickens the boot bottom too much. Another is to cover the bottom of the boot with rubber; but the rubber soles are apt to come off, as they have to be cemented on. Still another way is to have a rubber sole with a leather margin pegged on, and this we think has proved more or less satisfactory; but it is difficult to introduce it. What is needed is that common leather should be so prepared as to be impervious to water. It can be done—who of our hygienists will do it?

A HEAVY DOSE OF MERCURY.—A few days ago, says the *Gilroy Advocate*, of April 3, Mrs. Anna Babb's little boy drank a pound of quicksilver. The child is less than three years old, and even in California is considered rather young to indulge in so strong a beverage. He found the mercury bottle in some rubbish in an old trunk, while playing, and drank the whole, leaving but a few drops. The physician was sent for, who administered some light remedy. The child gave no other indication of having taken the mercury than drowsiness. The metal did not all leave the stomach for ten days, but he was about all the time, and is now bright as ever.

A DOG WITH THE MEASLES.—A house dog in Upton, Mass., had the measles simultaneously with the children of the family, from whom he caught the disease. He was carefully doctored, and was getting along finely, when one day he slipped out of doors and played in a snow bank. This indiscretion was fatal. He took cold and died.

DOMESTIC ECONOMY.

Cooking For Invalids.

Following are some excellent hints, taken from *Arthur's Magazine*, in reference to cooking for invalids:

Let all the kitchen utensils used in the preparation of invalids' cookery be delicately and scrupulously clean; if this is not the case a disagreeable flavor may be imparted to the preparation, which flavor may disgust and prevent the patient from partaking of the refreshment when brought to him or her.

For invalids, never make a large quantity of one thing, as they seldom require much at a time, and it is desirable that variety be provided them.

Always have something in readiness; a little beef tea, nicely made and nicely skimmed, a few spoonfuls of jelly, etc., that it may be administered as soon almost as the invalid wishes for it. If obliged to wait a long time, the patient loses the desire to eat, and often turns against the food when brought to him or her.

In sending dishes or preparations up to invalids, let everything look as tempting as possible. Have a clean tray cloth laid smoothly over the tray; let the spoons, tumblers, caps and saucers, etc., be very clean and bright. Grael served in a tumbler is more appetizing than when served in a basin or cup and saucer.

If the patient be allowed to eat vegetables, never send them up under-cooked, or half raw; and let a small quantity only be temptingly arranged on a dish. This rule will apply to every preparation, as an invalid is much more likely to enjoy his food if small delicate pieces are served to him.

A mutton chop, nicely cut, trimmed and broiled to a turn, is a dish to be recommended for invalids; but it must not be served with all the fat at the end, nor must it be too thickly cut. Let it be cooked over a fire free from smoke, and sent up with the gravy in it, between two very hot plates. Nothing is more disagreeable to an invalid than smoked food.

To Weave Hair.

A writer in *The Household* gives some very plain directions how to weave hair: Take a smooth board one and a half feet long and six or eight inches wide. Near one end drive three shingle nails in a row, the nails being half an inch apart and the row running parallel with the end of the board. At the other end, opposite the middle nail, drive one nail; wax three pieces of linen thread, tie them together at one end, and about a quarter of an inch from this knot tie another. Now slip it over the nail that stands alone, then tie one to each of the three nails, drawing the thread considerably tight.

Take the board on your lap, with the three nails toward the right hand. Next take a bunch of hair, both the ends evened, the size of a knitting needle, wet that end and put it under the thread nearest you, over the middle thread and under the last, then bring it back on the left side, reversing the order. Now push it close up against the knot. Proceed in this way until the strip is of the required length. After it is dry it can be pushed together more closely. Twist is superior to linen for durability.

GOON PIE CRUST.—Many persons have difficulty in making pie crust, often finding it heavy and dark. A lady writer in the *Vermont Journal* gives directions how to avoid this: To one quart of flour thoroughly mix one small teaspoonful cream tartar, one teaspoon of lard, (less will do,) lightly rubbed in the flour, one teaspoon salt, half teaspoon soda dissolved in very cold water. Mix lightly with a knife, pouring in a little of the water at a time. Do not wet all the flour, and do not knead it. If you want the top crust to resemble puff pie crust, roll out some of your dough and spread on lard, sprinkle on flour, then roll up. Now, do not do as I used to, cut off a piece and turn the edges up and roll out. I have learned a better way. Roll with your rolling pin a piece large enough for your top crust, just as it lies rolled up on your board. Wet the bottom crust around the edge with cold water before putting on the top crust. Do not pinch the edges of the top crust down. Cut or prick, to let the air out while cooking. Bake in a quick oven and you will have a nice looking pie.

DRESSER MUTTON.—To have it as it should be, the dish must be lined with mashed potatoes, the mutton nicely minced and properly seasoned, placed in the dish, a little stock added, and then covered over with mashed potatoes roughed with a fork, and placed before the fire till the little dish assumes the appearance of a nicely-browned baked hedgehog. The hotter served, the better relished, provided it has only been allowed to simmer and not to boil.

DOUGHNUTS.—Boil one quart of new milk and melt in it half a pound of butter. Beat three eggs with two pounds sugar, and add the boiling milk, stirring all the time. When nearly cold stir in a teaspoon of yeast, a teaspoon of salt, and flour to make stiff batter. When quite light knead in flour to make a soft dough. Let it rise again till very light, roll, cut in strips, and fry in hot lard.

The Interruption of Railroad Travel.

If this journal was dependent upon its Eastern exchange list for the matter to fill its columns the editor would be compelled in this issue to apologize for want of "original" matter. The interruption to railroad travel caused by the washing away of many miles of the track of the Union Pacific road not only kept back the mails but detained several thousand passengers and a large quantity of freight. The trouble occurred east of Green river. The road-bed at this point is but an elevation of the loose soil of the alkali desert, which, as it became saturated with the heavy rains and freshets from the mountains, turned to mud, and, as it were, melted away.

The vanguard of the detained travelers arrived here on Sunday, the 25th inst., and they have been pouring in ever since. There are, we understand, over 2,000 westward bound freight cars lying upon the side tracks east of Green river. Those started from Omaha last will be the first to come through, so that our merchants will be put to some inconvenience on account of the detention of expected goods.

The company is making strenuous efforts to get the track in shape again, and it is probable that the late ten days' embargo may be productive of good in causing them to put the road in better and more durable condition.

California Fire Clay.

The constant and increasing rich discoveries that are being made in California are not by any means confined to the richer minerals. Gold and silver seem to be the most sought after, as they are both precious metals and their glitter exerts upon every human mind a powerful attraction. But it should be borne in mind by those engaged in mining, that in prosecuting their researches it is very possible the mine may contain other substances of value. In Cerro Gordo mining district, Inyo county, which is exceedingly rich in argilliferous galea ores, there exist immense beds of fire clay, said to be as good as any ever discovered in this country, the product of which has been used in the Cupola furnaces in that district for several years, proving itself equal to the best English fire clay.

The existence of good fire clay in the immediate neighborhood of rich mines like those of Cerro Gordo district, is of special importance to the miner. It is also of great importance to our iron workers, and manufacturers of all kinds who use furnaces. It is pleasant to know that fire brick and clay can be made of California material and so many dollars kept at home. The prosperity of a State as well as an individual is reckoned by what is saved, and any article of commerce or consumption that can be supplied at home is another leak stopped.

This State has heretofore paid out half a million dollars annually for English fire brick and fire clay. It is to be hoped that the people in Cerro Gordo district will turn their attention to the manufacture of fire brick, and as it exists there in inexhaustible quantities, the clay will be found almost, if not quite as great a source of wealth as their silver. The demand for this article is not at all limited, but as manufactures multiply and mines are developed, the demand increases. Fire brick are worth \$40 per thousand and fire clay \$20 per ton. This important mineral wealth should not be permitted to lie dormant any longer. The Golden Gate plaster mill in this city recently ground up ten tons of this Cerro Gordo clay, and Selby's reduction works have also used about 20 tons of California fire clay.

Short Lectures on Patents.

No. 2.—By JNO. L. BOONE, of Dewey & Co's MINING AND SCIENTIFIC PRESS Patent Agency.

In my former article I pointed out the general rules that govern patents for the protection of both the inventor and the public. I will now consider

What May be Patented.

As a rule, anything that is new and useful can be patented. No matter how small and insignificant the invention may at first appear, so long as it can be shown that it possesses the elements of novelty and utility, it can be made the subject of a patent. Many of our most valuable patents cover inventions which appear at first sight to be too insignificant to patent.

Many small ideas have been given to the public by inventors, because they thought them too simple to warrant the issue of a patent covering them, which afterwards came into such general use that their possession under a patent would have been a fortune. Such an invention was the turning of the stamp and stamp stem in quartz batteries, in order to cause the face of the stamp to wear evenly. This invention can be found in use to-day in almost every quartz mill in existence; yet it was never patented.

If Howe had concluded that the idea of placing the eye of the needle near the point was too simple to patent, he never would have accumulated the vast fortune he did, and perhaps we would not have the sewing machine to-day in its present complete form. As a rule the simplest inventions are the most valuable. It requires less capital to place them before the public, and the returns to the inventor are more speedy, hence they are more profitable than more complicated inventions.

It frequently happens that an imperfect or useless machine can be made of great value by the addition of a simple improvement. To own the patent for the improvement in such a case is equivalent to owning the patent for the entire machine.

When an inventor has discovered that he can do anything in a better manner than it was done before, or produce a better result, or can obviate previous difficulties by means new and not used before for the same or an analogous purpose, he need not stop to ask whether the device is too simple to patent. Such cases can always be patented.

Attaining Perfection.

Few inventions are perfected by one inventor single-handed, but they generally pass through many hands before any degree of perfection is attained. That is, one man invents the principle and gives it form and existence, while many men are required to complete it and give it the best form and adaptation. But a small proportion of the patents issued from our Patent Office cover original principles—they are chiefly improvements, and as such

they are none the less valuable, none the less useful to the world, as the one is necessary to the other in order to benefit mankind.

The First Models

Of all our great inventions, the steam engine, the sewing machine, the electric telegraph, and numerous others—were but the crude embodiments of the ideas which they represent, and the credit of bringing them to their present state of perfection must be awarded to improvers; and many of the points that enter into their construction are extremely simple, but none the less valuable in the working economy of the machines. Without them the machines could not successfully or economically be operated, hence the patents covering them are valuable and profitable.

When a person contemplates

Applying for a Patent,

His first step is to construct a model. The law requires that this model be made inside of twelve inches in size each way. Model making is usually very difficult work. It requires special tools and close workmanship. Few inventors are mechanical enough to construct their own models, especially if their inventions are complicated. They therefore have to entrust their secrets to a model maker, or to persons who are competent to construct models. Some model makers are dishonest and attempt to take advantage of the inventor, but I believe such cases are exceedingly rare. Inventors should be careful to have good witnesses to their invention, or secure a caveat before they entrust them to model makers, so that in case of trouble they can prove priority.

Commissioner Fisher, however, stated in a decision regarding the conflicting claims of an inventor and a model maker, that "the office always looked suspiciously upon the claims of model makers where they conflicted with the claims of another party, especially when the model maker had been engaged to construct a model for the other party." If the inventor has plenty of witnesses to his invention he need have no fears of its being wrongfully taken away from him permanently.

Keeping Inventions Secret.

It is a great error of some inventors to suppose that when they have made an invention it is policy to keep it absolutely secret from all the world for fear that some one will attempt to claim it ahead of them. In European countries where patents are issued to first applicants, and where first applicants are understood to be first inventors, such a course would not only be wise, but necessary, but in the United States where the rights of the actual inventor are so strongly guarded, and where proof of priority will even procure a second patent, it is necessary that an inventor should exhibit his invention to at least a few of his friends in order to be able to establish priority in case of trouble. Where an inventor attempts to keep his invention a secret from every one, the great danger is that some person might by stealth, or by other means, obtain a knowledge of the secret and apply for a patent in advance of him. When this is the case it will be readily seen that there is no hope for the secret keeper: he has no witnesses or witnesses to call upon to establish his priority, he is powerless, and the patent thief is absolutely safe. But if he had taken a number of his friends into his confidence, or if he had publicly and openly exhibited his invention, so that all the world, for that matter, might know who it belonged to and who the inventor was, it would be a bold man indeed who would attempt to claim it in the face of such testimony. I am speaking now of inventions which have been perfected and represented either by a working model or a machine, so that the inventor knows what he desires to claim. It is not so, however, where the inventor has merely conceived an idea which he proposes to work into practical form. In this case the law provides him protection while he is experimenting upon his theory by allowing him to

File a Caveat

In the patent office, and thus prevent a patent from being issued to another person while he is experimenting, without his being duly notified and allowed to file his claim and demand an interference. It would be well in such a case even after the caveat is filed, for the inventor not to explain his idea or theory too freely, as such a course might

Stimulate Competition

And create unnecessary trouble, but when the invention is perfected, the sooner the inventor exhibits it to reliable witnesses the better it is for him, and usually, as above stated, the more witnesses the better.

[These lectures, with additional information for inventors and patentees, will be issued in book form by the publishers of this journal.]

MINING LAWS AND FORMS.—The proprietors of this journal have just published in pamphlet form, the United States Mining Laws and Regulations thereunder, together with the forms required under the Act of May 10th, 1872, in relation to locations, etc. These forms are official, having been adopted by the land office. The necessity has been felt of a compilation in a cheap form of the laws of the United States relating to mining, such as this pamphlet furnishes. All the information most needful to the miner will be found in its pages, and it is placed at a price—50 cents—which makes it accessible to all. Those desiring copies can address Dewey & Co., Publishers MINING AND SCIENTIFIC PRESS, 224 Sansome street, San Francisco.

Information for Miners.

We conclude this week a very long and detailed article on hydraulic mining, which has been running in the PRESS since Nov. 28th, 1874. The article is the most exhaustive one on the subject ever written, and the author, Mr. Waldeyer, has had such an extended practical experience in the matter, that what he has written is interesting not only to the general reader, but to the practical miner. He has described all the operations connected with hydraulic mining in detail, and the article is noticeably free from any theories on any subject, being confined principally to a description of the proper methods and apparatus for working, and succinct statements of facts connected with the subject.

All the engravings with which this article was illustrated were made by our own engravers, and we trust that they have been satisfactory. The subject is such an important one that we have given it considerable space, knowing that it would be appreciated by many of our readers. The value of a single article of this class is worth more to a miner than a year's subscription to the PRESS, and we shall endeavor, as we have done, to obtain matter of a similar character, from practical men, for the benefit of our readers. We will shortly commence the publication of an article of interest to quartz miners, giving hints on the Washoe process, by J. M. Adams, M. E., of Silver City, Idaho. It does not profess to be a complete and systematic description of the Washoe process. It contains no detailed descriptions of machinery, no discussions of chemical reactions, and but few explanations of fundamental principles. It is addressed to those who are supposed to understand these things already, and therefore to be able to appreciate the value of suggestions drawn from practice.

If our mining friends would send us occasionally word of any little improvements or new things they may come across, which are useful to them, they might also be useful to others. We are always glad to publish any practical suggestions that may come before us, and urge our readers to spare an hour or so occasionally for the benefit of fellow-workers. A knowledge of elegant diction is not necessary. Put your ideas down in any shape they come to you, and we will fix them up for publication. Miners and mechanics are too apt to think that they cannot write and keep what they know to themselves. Cicero, in his letter to his son Marcus, in *De Officiis*, says that the person who gives a light from his torch to a traveler in darkness loses none of that light himself, while at the same time he makes glad the heart of him who was before in the dark. This is as true now as it was when Cicero first wrote it, but the principle is too often lost sight of. Information can be imparted without detriment to any one, which will be beneficial to many. We hope our hint will be taken, and that some of our readers will assist us in our endeavor to make the PRESS as interesting and valuable as possible.

Mariposa Estate.

A full force of laborers and miners has been put at work on the new tunnel, near the Fulton mine, on the celebrated Mariposa estate. This tunnel is expected to develop many veins through which it will pass in its course the Pine tree vein. Workmen have already removed the rails and ties from the railroad on Devil's gulch, and graded the bed so as to make a good wagon road to the river, a way long felt. Mariposa county, although it possesses many quartz veins outside of the Mariposa grant, has of late years failed to attract the attention of quartz miners to the extent the merits of its ledges would deserve. Among the prominent mines not within the boundaries of the grant are the Ferguson, (owned in England), the Washington, Maxwell Creek and Hite's Cove. The only prominent mines in the county which have run with regularity of late have been the Hite's Cove and the Washington.

The new company which is operating the Mariposa property is doing little except running the tunnel mentioned above, which enters at the Merced river, near the Cphir mills. It follows the course of the Pine tree vein, but keeps outside of the vein in the date or country rock, which can be more cheaply excavated. Several encouraging discoveries have been made on the surface in various parts of the grant. It is to be hoped that no further interruption of this work will occur until the tunnel reaches the lode, so that cross-cutting can be done as soon as possible.

In the Dayton mine, on the Comstock, the water in the shaft, instead of rising to the drain tunnel as expected, yet lacks over 90 feet of reaching that point, showing that the strength of the great reservoir is virtually exhausted.

It is reported that the grave of Vasquez has been opened, and the head taken from the body and carried off.

(Continued from Page 281.)

discharged, being received in a car, shate, or other conveyor, according to the construction of the mill.

The door in the back of the flue furnishes a ready means for sampling and examining the condition of the ore in its progressive stages, and in some cases the salt is not added to the ore until subsequent to desulphurizing, in which case this flue door is conveniently used.

Other Uses of the Cylinder.
The cylinder has been found to give excellent results in roasting the compound auriferous pyrite ores to be treated by the Plattner process, in which case a small quantity of charcoal is subsequently introduced to the charge, so as to facilitate the decomposition of the resultant sulphate of copper. This form of cylinder is undoubtedly well calculated for the manufacture of soda from cryolite, roasting cement, plaster of Paris, ores of zinc, lead, copper, etc. In a word, it is admirably adapted to most roasting and reverberating furnace operations.

Cost, Weight and Capacity.
The cost of a cylinder, including its supporting and rotating machinery, iron work for fire box, bolts for foundation, and all royalties on patents, is about \$2,000. The total weight of the foregoing parts is 16,000 pounds; the placing of the foundation and erection of brick work, for fire box, cylinder linings and dust chambers, will vary greatly according to local circumstances. The capacity of a cylinder in twenty-four hours is, as reported by Mr. Chas. E. Sherman and endorsed by B. O. Cutter, eight to ten tons, the chloridizing being up to twenty-six per cent. These statements are based upon their experience at the Caribou mill, Colorado. A. D. Breed, Esq., proprietor of the same mill, gives the actual total cost of roasting and chloridizing as \$5.50 per ton. This low cost renders it feasible to work with profit very low grade ores. This furnace has been examined and favorably spoken of by Prof. R. W. Raymond, United States mining commissioner; Clarence King, in charge of Geological Survey of Fortieth parallel; Guido Kustel, Barlingame, Superintendent Tennessee mill, Silver City, N. M.; A. Walters, Superintendent United States mint, Boise City, Idaho; H. Stoetling, Territorial assayer of Colorado; J. M. Locke, C. E.; Prof. Dawley, Chas. E. Sherman; B. O. Cutter and A. D. Breed, all of the Caribou mill, Colorado. The manufacturers claim for the furnace the following advantages: first—a most thorough and uniform accomplishment of its work; second—complete control of its action irrespective of the character of the material acted upon; third—a high per centage of chlorinations, and therefore, of yield, with ores of the precious metals; fourth—low cost; fifth—little wear and tear and ease of repairing; sixth—skilled labor is not a requisite in its management; seventh—the size of the apparatus permits it to be readily adapted to the size of a mill by simple adaptation.

Perfecting Arrangements for the Tenth Industrial Exhibition.

In the Press of April 17th we gave some particulars of the additions now making to the Mechanics' Pavilion and the extra inducements offered by the Society in the way of premiums, etc., for the tenth exhibition, which opens on the 17th of August, next. A meeting of the Board of Managers was held at their room in the Mechanics' Institute building, on Tuesday evening, the 27th ult. Vice-President B. B. Conhall presided, and most of the managers were present. The Executive Committee reported that the painting of the Pavilion has been completed to their satisfaction, and in accordance with the contract. Also that the smoke-stack and all out-door appurtenances of engines and boilers are being painted and put in order. The Horticultural Garden Committee reported that a large number of plants and trees have been purchased and placed in the garden, and are doing finely. The importance of a thorough and practical test of the powers of the different engines and machinery that will be exhibited has been fully considered by the Board, and they have decided to adopt the plan used by the Royal Agricultural Society of England, which is the most perfect and correct of any yet invented. The proper apparatus and machinery will be made here immediately, the estimated expense being \$1,500. Plans and detail drawings, of the same have been received from the office of the Engineer, London, by Mr. Jas. Spiers, Chairman of the Committee. The Secretary, J. H. Culver, reported that large number of applications for space have been received, and an exhibit of almost every product and manufacture of the Pacific coast, as well as the raw materials, is already assured. An invitation was extended to the Photographic Society of the Pacific to use the art gallery of the Pavilion for the National Convention of photographers to be held here in July next. The floor of the old horticultural garden will be relaid, and the main shaft extended two hundred feet. The additional area for machinery will be 50x210 feet, giving 10,500 square feet more than the former Fair did.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Mining and Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

STEAM GENERATOR, WATER HEATER AND STEAM MOTOR COMBINED.—Sebra R. Mathewson, Gilroy, Santa Clara county, Cal. This invention is intended to provide a general utility apparatus for farmers and dairymen. It consists of a steam generator, water heater and motive power combined in one machine, and is provided with conveniences to adapt it to the various uses to which it is to be applied. A case or shell is made of boiler iron or suitable material. In the lower part of the shell is an annular chamber surrounding the furnace or fireplace, and extending as high as the fireplace. The boiler used is annular in shape, and has an outside shell surrounding the outside and top and extending down in the tubular space inside of it almost to the bottom, so as to provide a space between boiler and shell. The heat and products of combustion from the fireplace, in order to pass out through the stack or chimney at one side of the shell, is compelled to pass up through the space between the boiler and its shell, outside of the boiler, then

across the top of the boiler, and down its inside until it enters the tubular space inside of the boiler. Thence it passes around the motor before it reaches the smoke stack. On top of the case is placed a rotary engine surrounded by a case so as to leave a space around it. This space communicates with the space above the boiler upon one side and with the space between

the boiler and outside shell upon the opposite side, so that the heat, after passing around the boiler, will also pass around the engine and thence to the smoke stack. The apparatus is arranged so that the steam may be cut off before it enters the engine and turned through a branch pipe, or the exhaust may be directed through branch pipes and conveyed to any desired point. A draw pipe, with cock, leads from the annular water chamber through the shell, so that hot water can be drawn from the chamber when desired. The inventor claims that the arrangement of the machine is such that he greatly economizes fuel by entirely surrounding the boiler with the flue space so that the heat from the furnace will pass entirely around it and then around the engine before escaping, thus enabling the apparatus to be worked economically. The end of the smoke stack is covered with a double netting, the inner netting being very coarse while the outer one is fine, so that any sparks which pass through the inner or coarse netting will lodge between the two, thus avoiding danger from sparks. This will be a specially useful dairy power apparatus, and is mainly arranged for that purpose.

UNIVERSAL GAUGE QUILTER AND CORDER.—George Vincent, Stockton, California. This is an attachment for sewing machines which the inventor calls a universal gauge quilter and

Hydraulic Mining in California.

No. 23.

Being then forced to acknowledge that a broad and shallow stream facilitates the catching of gold, we must ask why are all our sluice-boxes not constructed on the principle of under-currents, wide and shallow? The answer is that the heavy and large material (boulders and pieces of hard clay or cement), needs a deep current of water to carry it along.

If, therefore, a separation of the finer gravel from these boulders, etc., were effected, no reasonable obstacle would remain to the application of that principle in gold-washing which has been sanctioned by the practice of thousands of years, and which our modern time, with all its advances in science, cannot improve, but only imitate.

The practicability of such an application in gold washing, even for the large hydraulic operations, may be illustrated by the subjoined sketch, which, though not executed with regard to proportions, represents with sufficient clearness a section of main flumes or sluices, running on a grade of six inches per twelve feet, and tapped every 250 feet for its whole length.

The distance between tap I and tap II would, therefore, be 250 feet, and between tap I and tap III 500 feet. The platforms have only a grade of four inches per twelve feet, and the gain in height by this lessened grade would be for a distance of 250 feet about 3 1/2 feet, which gain is spent in a drop at tap II, where a larger platform receives the strained gravels of taps I and II. Where the gravel and water drop off is inserted a deep, strong box, well charged with quicksilver. To the bottom of this box an iron pipe is led, which discharges a stream of water under a regulated hydrostatic pressure and in adjustable quantities.

In this way the quicksilver would be kept always in motion, and the gravel itself would be subjected to an excellent crushing process. (See sketch, pipe .1.) Pipes 2 and 3 inject streams of pure water under the grating to keep the box clear, and to supply also more water to wash the gravel over the widened platforms.

This process may be repeated for the whole length of the sluice-boxes. The size of the gravel may be reduced by repeated straining, as described above.

The undeniable advantages of this mode of working can be stated in a few words:

First. All the fine gravel and sand, in which most of the fine or rusty gold is carried off, will be submitted to a continuous washing over under-current platforms, without ever being returned to the main sluices. The reduced grade on these platforms is equalized by an addition of pure water, which will permit an easier settling of the gold than a swift and muddy stream.

Secondly. Repeated drops, connected with a strong hydraulic jet, will do a great deal for the scouring of rusty gold and the general breaking up of the washed material.

Thirdly. A reduction of the gravel to the smallest size can be easily attained by repeated straining as mentioned before, so that the largest pebble would only equal a pea in size.

To prevent this fine-gravel wash from "baking" requires only a very simple arrangement. A frame-work resembling a common harrow can be placed on the top of the platform, the teeth downward, and touch with their points the riffles of the platform. This arrangement would secure the breaking of the stream at a hundred or more points, and could be removed and replaced at a moment's warning. (See engraving.)

Where motive power can be procured as easily as on large sluice-boxes running a large and rapid stream of water, this barrow might be put in slow motion by an undershot-wheel, the frame of the harrow running on rollers upon the sides of the platform.

This sort of machinery is the simplest in construction, and could be used, perhaps, with great beneficial effect, and without that wear and tear which any more complicated machinery would suffer by the treatment of such an enormous quantity of material as continually passes over the long line of platforms.

The writer submits the foregoing suggestions, trusting not only to gain the favorable judgment, but also to arouse the inventive energy of those to whom we owe already the present advanced condition of the art of hydraulic mining.

Condensed from an article by Charles Waldeyer, in the last Annual Report of the U. S. Commissioner of Mining Statistics.

In the Globe consolidated mine on the Comstock the steady, strong flow of water from the main west drift on the 400-foot level has stopped all work in that portion of the mine at present. When the ledge was cut by the south cross drift the burst of water was so great that it was with difficulty that the workmen escaped with their tools. The water immediately filled the drift and station, and raised twelve feet above the station in the shaft, at which point it still remains.

Sluice-washing of the future. I, II, III, taps; 1, 2, 3, auxiliary jets.

Fig 3. Transverse Section of Bruckner Revolving Furnace.

the boiler and outside shell upon the opposite side, so that the heat, after passing around the boiler, will also pass around the engine and thence to the smoke stack. The apparatus is arranged so that the steam may be cut off before it enters the engine and turned through a branch pipe, or the exhaust may be directed through branch pipes and conveyed to any desired point. A draw pipe, with cock, leads from the annular water chamber through the shell, so that hot water can be drawn from the chamber when desired. The inventor claims that the arrangement of the machine is such that he greatly economizes fuel by entirely surrounding the boiler with the flue space so that the heat from the furnace will pass entirely around it and then around the engine before escaping, thus enabling the apparatus to be worked economically. The end of the smoke stack is covered with a double netting, the inner netting being very coarse while the outer one is fine, so that any sparks which pass through the inner or coarse netting will lodge between the two, thus avoiding danger from sparks. This will be a specially useful dairy power apparatus, and is mainly arranged for that purpose.

metal plate. On the outside of each of the gable ends and just below the tops of the sides is secured a wooden strip which extends entirely across the ends of the case. The case cover is constructed similar to the roof of a building, with two sloping sides and a horizontal top strip secured together by wooden braces or gables. The cover fits down over the truncated gables of the box case and the braces or gables of the cover are placed far enough from the ends of the cover to fit down inside of the box gables and allow the horizontal top strip to rest on the metal plate outside of them. The sloping sides of the cover and these form a roof for the case. A lock can be used, if desired, to secure the cover to the sides of the case. When this cover is removed the entire top of the case is open, so that the bottle or demijohn can be removed without trouble. The outside strips serve as handles or gripping pieces for the hand when moving the case about. By this means Mr. Newman provides a cheap and very convenient case for bottles, which has the advantage of allowing the bottle to be easily removed when desired.

THE President of the French Geographical Society has handed Minister Washburne the gold medal presented by them to the family of the late Captain Hall, in commemoration of his exploration of the Arctic region.

OVER \$3,500 PER MONTH SAVED

BY THE USE OF

Hendy's Improved Amalgamator and Concentrator

Can be seen at the Manufactory, No. 32 Fremont Street, San Francisco.

SAN FRANCISCO, April 27, 1875.

JOSHUA HENDY, Esq.—Dear Sir:—As a practical miner and millman, I take pleasure in recommending the
use of your Concentrators in all mills where gold or silver ores are reduced. No mills should be without them,
for the following reasons:

1st. They are good sizers (no perfect concentration in pulverized ores can be effected without first sizing).
2d. The best Concentrator I have ever known—(the concentrated stuff only containing 5 per cent. of sand).
3d. They are good amalgamators, light (feathery) particles of amalgam and particles of coated gold by at-
trition are brightened, and from their specific gravity and the action of the pan, fall to the bottom and adhere.
4th. They require but little power and attention to run them, and with ordinary care will last for years.
I have been familiar with the workings of your Concentrators for four years past; have run them myself in
the North Star Mine, Grass Valley; am familiar with their practical workings on the Empire Mine, Grass Valley;
St. Patrick, Placer Co.; St. Lawrence, El Dorado Co.; Oaks and Reese, Mariposa Co., and most cheerfully give
you this testimonial. For further information you are at liberty to refer to,

Yours respectfully,
409 California street, or Cosmopolitan Hotel.

JAS. H. CROSSMAN, M. E.

SAN FRANCISCO, February 10, 1874.

OFFICE SUPERINTENDENT OF KEYSTONE CON. M. CO., AMADOR, AMADOR COUNTY.

MR. J. HENDY—Dear Sir:—In answer to your inquiries as to your Concentrators furnished our company
last July, I would say that I am more than pleased with them; and the saving to the company has been over
\$3,500 per month more than with the blankets and buddies formerly in use. O. C. HEWITT, Supt.

OFFICE SUMNER MINE, KERNVILLE, April 27, 1874.

J. HENDY, Esq.—Dear Sir:—Having four of your Concentrators in use at our Mills for four or five months,
which for saving Amalgam and for concentrating Sulphurets, are a success, beyond a doubt, I feel it a duty
due you and those interested in Quartz Mills, to recommend them.
As further evidence of their worth, I now order TWELVE more of your Machines for our new Mill, now in
course of erection. E. R. BURKE, Superintendent.

For description send for Circular.

This is a Sure Cure for Screw Worm, Scab
and Foot Rot in Sheep. It also kills Ticks,
Lice, and all Parasites that infest Sheep.Prevents scratching and greatly improves the quality
of the wool. One gallon of the Dip properly diluted
with water will be sufficient to dip one hundred sheep,
so that the cost of dipping is a mere trifle, and sheep
owners will find that they are amply repaid by the im-
proved health of their flocks.This Dip is guaranteed to cure when used according
to directions, and to be vastly superior to Corrosive
Sublimate, Sulphur, Tobacco, and other remedies which
have heretofore been used by farmers.Circulars sent, post paid, upon application, giving
full directions for its use, also certificates of prominent
sheep growers who have used large quantities of the
Dip, and pronounce it the most effective and reliable
known Cure and Preventive of Scab and other kindred
diseases in Sheep. mrl3-bp

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and recently
introduced for general family use in San Francisco and
neighborhood, is already in great demand. It is now the
intention of the manufacturers to introduce it all over the
Pacific Coast, at prices which will bring it within the reach
of every household.

It is unequalled for cleansing Woolen Fabric, Cutlery,
Carpets or Crockery; for Scrubbing Floors, Washing Paint,
Removing Grease Spots, Shampooing or Bathing.

It renders water soft, and imparts a delightful sense of
coolness after washing.

DIRECTIONS.—For Laundry, use two to four table-
spoonfuls to a wash-bow of water. For bathing, use one
tablespoonful in the bath tub. For removing grease spots,
apply with a brush, undiluted, and wash with water after-
ward. For stimulating the growth of plants, use a few
drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bot-
tle, 40 cents; per Half Gallon, 75 cents.

Also, SULPHATE OF AMMONIA for chemical pur-
poses, fertilizing, and the preparation of artificial manures.
AMMONIACAL PREPARATION, for the prevention and
removal of hoarse voices. CRUDE AMMONIA, for general
manufacturing, and PURE LIQUOR and AQUA AMMO-
NIA for chemical and pharmaceutical purposes.

Manufactured by the
SAN FRANCISCO GAS-LIGHT CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they
have no equal. No effort has been, or will be spared
to have them constructed in the most perfect manner
and of the great number now in operation, not one has
ever required repairs. The constant and increasing de-
mand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly
into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:
The pan being filled, the motion of the muller forces
the pulp to the center, where it is drawn down through
the aperture and between the grinding surfaces.—
Thence it is thrown to the periphery into the quicksilver.
The curved plates again draw it to the center, where it
passes down, and to the circumference as before. Thus
it is constantly passing a regular flow between the grind-
ing surfaces and into the quicksilver, until the ore is
reduced to an impalpable powder, and the metal amal-
gamated.

Settlers made on the same principle excel all others.
They bring the pulp so constantly and perfectly in con-
tact with quicksilver, that the particles are rapidly and
completely absorbed.

Millmen are invited to examine these pans and settlers
for themselves, at the office, 229 Fremont Street,
San Francisco

imore Consolidated for
ican Flat. The Baltim

timore Consolidated for each share of American Flat. The Baltimore Consolidated company has also declared a stock dividend of one share of the Maryland mining company for each share of the Baltimore Consolidated stock. The Idaho stocks seem to be gaining in favor. Poorman and Golden Chariot largely while War Eagle and South Chariot are firm. The reported strikes in Golden Chariot brought it up a little, and the division of the stock also assisted it to some extent. The Idaho mines have been in the background so long that the

favorable reports of the
congratulating Raymond C.

favorable reports of the local papers are encouraging. Raymond & Ely holds its own very well, which is good for Ely district stocks, and that mine leads them all and encourages the owners of the other mines. On the Comstock everything seems to be going on as usual. New hoisting and pumping works are going up in all directions, and legitimate mining seems to be in the ascendant.

LIMESTONE SPRING, S. C.

Golden Medical Discovery, Purgative Pellets and Dr. Sage's Catarrh Remedy, they having cured me of Catarrh of nine years' standing, which was so bad that I disfigured my nose, and, while curing it, your medicine also cured me of both hemorrhoids and piles.

times also cured me of Asthma in its worst and most aggravated form. Before using your medicines I had become reduced in flesh from one hundred and fifty-five to one hundred and fifteen pounds, and I now weigh one hundred and sixty-two pounds, and am in better

health then I have enjoyed for twenty years.

The above is but a fair sample of hundreds of letters which are received by Dr. Pierce, and in the face of

such evidence who can longer doubt that the Doctor's medicines cure the worst cases of Chronic Catarrh.

Wm. Forsyth Bynum & Son, druggists, of Live Oak
Fla., write, Sept. 16th. 1874, as follows: "Dr. B. V.
France, Buffalo, N. Y. Has Golden Medical Pills

PIERCE, Buffalo, N. Y.—Your Golden Medical Discovery and Purgative Pellets sell very largely and give complete satisfaction, as numbers of our customers

end friends testify with pleasure. Your Favorite Prescription is indeed the great Favorite with the ladies and numbers can say with joy that it has saved them

from eking out a miserable life or meeting with premature death, and restored them to health and happiness."

Thousands of women bless the day on which Dr
Pierce's Favorite Prescription was first made known

to them. A single hottle often gives delictets and suffering women more relief than mouths of treatment from their family physician. In all those derange-

ments causing back-ache, dragging down sensations, nervous and general debility, it is a sovereign remedy. Its soothing and healing properties are well known.

its soothing and healing properties render it of the utmost value to ladies suffering from internal fever, congestion, inflammation or ulceration, and its strength

ening effects tend to correct displacements of internal parts, the result of weakness of natural supports. It is sold by all druggists.

Dr. PIEROE's pamphlet on Diseases peculiar to Women will be sent to any address on receipt of two stamps.

Address as a boys.

descriptive Circular
and Prices.

COOK, RYMER & CO.'S Celebrated Hoisting Engines have been too long in use on the Pacific Coast to require any special recommendation from us. We refer with confidence to any one of the hundreds now in use. We simply state that they still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship for the sake of competing with cheaper engines. For details of sizes and price list. We desire to call particular attention to our new

MINING HOISTING ENGINES.

(Manufactured by the same parties.)

Which have just been introduced on this Coast. The plans and specifications are the combined efforts of our most successful MINING ENGINEERS, and the result is the most complete

DOUBLE-DRUM HOISTING ENGINE

Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. One of these engines may be seen at work in the Belcher mine, and one in the Ophir, on the Comstock lode, to both of which we refer. We have all sizes of these engines constantly on hand. For sale only at

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 25TH, 1874.]

Price Reduced to 18 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally.

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburgh Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 18 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chipping, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to
1729-3m
CAST STEEL SHOE & DIE CO., Room 1, Academy Building, S. F.

IMPORTANT TO LUMBERMEN.

LITTON SPRINGS
SELTZER WATER,
FROM LITTON PARK.

Near Healdsburg, SONOMA CO., CAL.

QUANTITATIVE ANALYSIS.

One wine gallon of water contains of solid constitu-
ents 228.69 grains, in the following proportions:

Carbonic Acid (combined).....	42.96
Chlorine.....	73.38
Sulphuric Acid.....	2.36
Silicic Acid.....	2.02
Oxide of Iron.....	2.85
Lime.....	4.41
Magnesia.....	5.24
Soda.....	62.19
Alumina.....	
Ammonia.....	
Potash.....	27.38
Lithia.....	
Boric Acid.....	
Organic Matter.....	
Total grains.....	228.69

The amount of free carbonic acid in the water which
escapes on standing and is not calculated in the above
analysis, is equal to 383.75 grains per gallon.

Nature's Specific for the Cure of Indigestion,
Costiveness, Piles, Irrregularities of the
Action of the Kidneys and Liver,
Inflammation of the Eyes,
Gout, Rheumatism, Etc.

Sold in Pint and Half-pint Bottles, and
also by the Gallon.

Delivered in any part of the City, and forwarded to
any part of the Country, by application to the Office.

Ayer's Cherry Pectoral,

For Diseases of the Throat and Lungs, such
as Coughs, Colds, Whooping Cough, Bron-
chitis, Asthma and Consumption.

The few compositions,
which have won the con-
fidence of mankind and be-
come household words,
among not only one, but
many nations, must have
extraordinary virtues. Per-
haps no one ever secured a
wide reputation, or main-
tained it so long, as AYER'S
CHERRY PECTORAL. It has
been known to the public
about forty years, by a long
continued series of marvel-
lous cures, that have won
for it a confidence in its vir-
tues, never equalled by any other medicine. It still
makes the most effectual cures of Coughs, Colds, Con-
sumption, that can be made by medical skill. Indeed
the CHERRY PECTORAL has really robbed these danger-
ous diseases of their terrors, to a great extent, and given
a feeling of immunity from their fatal effects, that is
well founded, if the remedy be taken in season. Every
family should have it in their closet for the remedy and
prompt relief of its members. Sickness, suffering and
even life is saved by this timely protection. The
prudent should not neglect it, and the wise will not. Keep
it by you for the protection it affords by its timely use
in sudden attacks.

An Improved Cut-off Valve.

The importance and necessity of a release of the steam pressure on the back of the common slide valve; the unreliability of cut-off at different points of the stroke, as well as its defect in distributing the steam equally in the backward motion of the piston compared with the forward motion of the same; the failure of a constant lead opening for forward, backward and mid-gear of the link motion, have been a subject of constant consideration among engineers. For many years numerous inventions have been brought before the public to overcome these imperfections, amongst which were the link motions of Stevenson, Gooch, Allan and Meyer, some of which have one and some have two slide valves, the upper one serving to control the expansion of steam. Mr. John C. H. Stut, of this city, has recently patented through the agency connected with this office an improvement on rotary reversing and cut-off valves, which he claims overcomes all the imperfections of the old link motion with very few moving parts and no complicated machinery, it being possible to turn all out with the lathe.

In the accompanying engravings, showing this valve, Fig. 1 is a horizontal section taken through *xx* Fig. 2. Fig. 3 is a vertical section taken through *yy* Fig. 1. Fig. 4 is a side view of the valve. Fig. 5 shows the operation of the valve. *A* is the steam cylinder, in which the piston is moved alternately from end to end. *BB* are ports which lead from the end of the cylinder to the cylindrical valve-chamber, *C*. In this case the cylinder is placed vertically, while the valve-chamber lies horizontally and the ports open into the chamber, one on the upper side and the other just opposite upon the lower side, in the form of elongated slots, which stand at a small angle transversely with the axis of the chamber, so that, if continued directly around, they would form spirals. This angle of the ports is plainly shown at Fig. 5, which represents the inside of the valve-chamber, unrolled, as it were, upon a flat surface.

This valve is also cylindrical, and is fitted so as to be steam tight within the chamber, as is fully described further on. The valve has two sets of openings, one exhaust, *D*, and one steam-port, *E*, lying in the same plane and opposite sides of the valves, while the other set of ports, *FG*, for reversing the engine, lie in a plane parallel with the first, the exhaust port, *F*, for the reverse motion, lying beside steam port *E*, of the forward motion, and steam port *G* of the reverse by the side of the exhaust port, *D*, of the forward motion, so that, by moving the valve endwise in its chamber, either set of ports can be made to open into the ports, *B*, and their width of opening can also be regulated. One end of the valve, *H*, is considerably smaller than the other part, as shown at *I*, and serves as an inlet pipe for steam. This pipe connects with the steam ports, the one not in use being at times closed, because it is always in contact with the inner face of the valve chamber, while the other alternately comes opposite the upper and lower steam port, *B*. The exhaust ports act in the same manner, and are connected with a passage through the interior of the portion, *J*, of the valve, which is hollow and open at its outer end, to allow steam to escape in that direction.

In order to allow of this end movement of the valve and still maintain the pipe, *I*, steam tight, it is accurately fitted to slide outside or within the conducting steam pipe, the joint being stuffed, so that the end motion can be effected without leakage.

The operation of this valve will be as follows:

The valve being set by means of any suitable lever-connection, so that one set of ports are in a line with the ports *BB*, of the chamber, steam is admitted and the engine moves. Any positive connections, as gearing, may be made between the engine-shaft and valve so that the latter shall move accurately and in conjunction with the piston. The steam ports, *E* and *G*, of the valve are in the present case two inches in length, while the ports, *B*, of the chamber are two and thirteen-sixteenths inches long.

By this construction this valve remains fully open while it is passing over this thirteenth-sixteenths difference in the length of the ports, which is of great advantage, as it gives the steam an opportunity to exert its full pressure,

the valve in its chamber so that when rotated it will uncover only a portion of the steam port, although the exhaust port is made enough wider to present sufficient clearance not to choke.

The ports, *B*, being, as before described, placed spirally around the chamber and one side, *c*, of the steam port, *E* or *G*, in the valve being also made to stand at an angle, as shown, it will be seen that where the variable cut-off is to be used the opening will be the largest when the ports, *E* and *B*, first meet, and the inclination of each will be such that, as the port *E*, passes over the port *B*, the opening will be gradually narrowed down, and may be entirely closed at any point in the stroke, the point of closing depending upon the distance which the

Operation of Valves.

STUT'S ROTARY REVERSING AND OUT-OFF VALVE.

and the size of the port is not so quickly reduced after its full opening.

The exhaust ports are equal in length to the bridge between the ports *BB*, of the chamber, (one-eighth less than the length of the ports, *B*), so that, as soon as it is entirely closed to one of the ports, it will be instantly opened to the other, and there will be no back pressure.

To reverse the engine, it will be necessary to slide the valve along in its chamber until the two ports, *F* and *G*, are brought to rotate in a line with the ports, *B*.

It will be seen from the length of the ports, *E* and *G*, that they will cut off the steam from the ports, *B*, some time before the piston reaches the end of its stroke, and this constitutes a constant cut-off, which is determined by the length of these ports. The distance between the outlet ports is equal to the length of the bridge, measured on the circumference of the valve.

The variable cut-off is regulated by moving

the valve has been moved endwise in the chamber. By this construction the inventor is enabled to adjust the amount of cut-off to the greatest nicety.

In order to keep this valve perfectly tight, the moving face is constructed in two semi-cylindrical segments, which form each half of the circumference of the valve. Their meeting edges are packed by means of a longitudinal strip, *h*, and two transverse strips, *i*, at the end of this longitudinal strip. The segments lie upon the interior portion of the cylindrical valve, and the ports correspond with the opening to the interior of the part, *I*. Suitable devices are employed to pack the meeting edges of these openings. Those desiring further information concerning this valve may address the inventor, John C. H. Stut, No. 182 Stevenson street, San Francisco.

THE NEW Belcher air shaft, which is completed to the 1000-foot level, is greatly benefiting the entire mine, by drawing off the hot air and cooling the lower levels.

Making Casks by Machinery.

At the California wine cooperage and mill company, 30 and 36 Spenser street, they are engaged on a contract for seventy-five or eighty large oval wine casks, capable of containing 3,000 gallons each, for S. Lachman & Co., Market street. These casks are all made of well seasoned Eastern oak and are very heavily hooped. At this cooperage a large portion of the work usually done by hand is done by machinery, making a saving of time and labor, and turning out truer work. In getting out their staves, the proprietors of these works, M. Fulda & Sons, first dress the staves into the required thickness. They are then steamed and bent to the proper curve or bilge; afterwards being placed on a saw and "listed" or edged up to the level desired. They are then jointed to different curves for different sized casks. After being jointed they are set up and heated over a fire to get them in proper shape. They are then ended off, concaved and grooved ready for the head. The heading is also steamed and bent to give extra strength to large casks.

The holes for the dowel pins in the heads are bored by machinery. After the different pieces of the head are driven together in the dowels, the heads are sawed into the proper size suitable to the groove or 'croze' of the cask. The heads are then put in the casks, planed off, and the hoops placed in proper position. All this except the finishing work is done by machinery. In tank building the work is almost entirely done by machinery, such as planing, jointing, crozing, sawing, boring heads, etc., leaving nothing

to be done but set the tank up.

At these works twenty-two men are employed in a general cooperage and mill business. In the mill department they do general jobbing, planing, sawing, etc. They are putting in more machinery, so as to carry on a more extensive mill business. The establishment occupies two full water lots. In making redwood water tanks they have apparatus and conveniences for taking out the color and taste of the redwood, where only cold liquids are to be used. Hot liquids will continue to draw out the color from this wood. They are about to commence work on a very large oak wine cask capable of holding 15,000 gallons. It will be oval, thirteen feet by sixteen, with staves twelve feet long. This is for S. Lachman's cellar on Market street, now the largest on this coast if not the largest in the United States. When the seventy-five new 3,000 gallon casks with the big 15,000 gallon one are put in with the great number already there, this wine cellar will be one of the sights for tourists to inspect.

IN THE Ophir mine the prospecting on the 1700-foot level now being done is principally for the purpose of determining the exact location of the foot-wall of the ledge. The erection of the foundations for the new incline machinery is making steady progress.

IN THE Hale and Norcross mine the north drift on the 2100-foot level has connected with the south drift on the same level from the Savage, affording a fine circulation of pure air, and greatly facilitating operations on the lower levels.

IN THE Yellow Jacket mine the water has been drained from the 1840-foot level, and work resumed at all points in that portion of the mine. The prospecting operations on the 1740-foot level are still pressed vigorously ahead.

PANAMINT is to have a Stetefeldt furnace.

CORRESPONDENCE.

Tunnel Work at French Corral.

ENTRERS PRESS.—In a recent tour through Nevada county your correspondent had occasion to stop for a few days at the mining town of French Corral. In strolling around through the cavernous openings and over the precipitous banks in the hills—that tell so plainly of the work of the "Little Giant"—his attention was attracted by a column of blue smoke passing up into the atmosphere from behind the abrupt bluffs of the Yuba. Turning his steps thither he soon stood upon the verge of the narrow canon through which the gold-burdened waters of the Yuba go rumbling onward toward the plains below. Peering downward through the tops of oak and fir trees, a glimpse is had of a low roofed building, by the side of which is an immense heap of newly emboweled granites with car track running from the dump toward the base of the hill, and then quickly disappearing. Reasoning in his mind what these things might indicate, and reflecting on the direction he had come, your correspondent was led to believe that he was standing directly over a heavy charge of giant powder that was being used in the excavation of a tunnel; and, although the towering hill seemed planted firmly on its base, a look of serious melancholy flitted on his countenance as if he had thoughts of home and friends. However, these thoughts were vain, for, upon following down the winding trail he was met at the foot of the hill by the genial face of the foreman of the works, Mr. C. S. Davis, who soon dissuaded his mind. After partaking of a bountiful repast, and when an hour had been pleasantly whiled away in social chat, we donned the miner's garb, and with a taper each marched slowly into the hill-side.

At the entrance we remarked the exceeding hardness of the rock, and in the whole length of the tunnel (some 1300 feet) saw scarce a seam or crevice. The dimensions of the excavation are 8x8 feet, and when we consider the solidity and flinty hardness of the walls, and its powerful adhesiveness, it was almost a source of wonderment to behold what was being accomplished in so short a time. But when we had reached the terminus of the tunnel, and stood facing the solid stone wall, apparently impenetrable, we would certainly have desponded of their making further progress, had we not noticed, standing quietly though defiantly beside us, what appeared to be a little mountain howitzer—harmless except when mounted upon a mule's back. This implement of warfare, however, proved to be not an enemy, but a friend to man—a rock drill. Having at other times seen various drills of similar construction, we were not disposed to give this any particular attention; but, learning from Mr. Davis that this was the only machine of its kind in operation on this coast, we were glad to give it more than a casual notice, and learn wherein it differed from other excellent machines that have been successfully used in California and Nevada.

It is called the Ingersoll rock drill, and is manufactured by the Ingersoll rock drill company, in New York city. The essential difference between this and other well known drills, as observed by your correspondent, was that this machine is self-feeding, while others require an extra attendant for this purpose. This is claimed as a decided advantage, for the reason that there can be no irregularity in feeding, and, as a natural sequence, no cramping of the drill occurs, besides the economy of dispensing with one attendant. Other points of superiority claimed by the company and attested by Mr. Davis (who knows by actual test what the machine is) are: its simplicity, portability, and power to do a great per cent. of work. When in operation it is almost free from the jar or vibration that is so destructive to machinery of like character.

In this tunnel—which, as I have said, penetrates a solid body of the hardest granite—the progress made is worth of remark, when we consider the size of the drill points used, and the fragile appearance of the little monster that does the work—the average progress made with two three-quarter inch drills being four feet to each eight hour shift, the pressure gauge of the compressor indicating a pressure not exceeding sixty pounds, and ranging the greater part of the time from forty-five to fifty-five pounds.

A word concerning the purpose of this tunnel might be of interest to your readers. As most Californians are aware French Corral was in early days an exceedingly lively mining camp, having a population numbering up into the thousands. The mining claims being chiefly placer or gravel were operated mostly by individual owners of small capital. This being before the days of wealthy mining corporations and extensive water ditches, mining was conducted in so primitive a mode that the bed rock (upon which the richness of the claim lies) was seldom reached on account of the absence of a natural outlet with sufficient fall to carry the

washings through the sluices. Hence, when the hill-tops had been washed down to the general level of the surrounding country, the claims were in some instances abandoned, while those that were still held remained for the most part unworked.

The greater part of this mining ground is now owned by the Milton mining and water company, this company also controlling a water privilege with extensive ditches, supplying all the mining claims at this and various other points with water for mining purposes. The work of tunneling the hill is projected and carried on by them, for the purpose of getting sufficient fall to work their claims to the bed-rock. It will, when completed, be some 3,000 feet in length, having a grade of eight inches to fourteen feet running measure.

This will give the mining interest of French Corral a new impetus, as there is abundance of good pay dirt to keep the hydraulic pipes at work for several years to come.

The company are now washing quite extensively, giving employment to quite a number of men in this, as well as keeping a full force at work at both ends of their tunnel. Mr. V. G. Bell is superintendent and N. C. Miller, secretary, both of whom are residents of the place and have their office there. I will endeavor to give you notes of progress, etc., from other places in the county that I visited. L.

Irrigation.

How our Plains may be Irrigated without the Aid of State Credit.

Of all the works demanded from the hands of men who will live hereafter in the State of California, there are none more important than the irrigation of the great valleys of the Sacramento and San Joaquin.

With a soil and climate suitable to the support of millions, and a productive capacity, under favorable circumstances, equal to all other portions of the State, a few thousand inhabitants now are scarcely able to obtain a livelihood, although a very large part of these valleys are under cultivation.

If the withholding of sufficient rain and the coursing of rivers every ten or fifteen miles means anything, it means that the energy of men shall cause these rivers to flow as rivulets over these plains.

It is assumed that all men know of the beauty, fertility and constancy of an irrigated country, and it is not necessary to state that orchards, forests, and an abundance of all kinds of vegetation will follow the spreading of water over the plains. This abundant vegetation, by the well known laws of nature, will cause a more plentiful rainfall, and thus benefit the neighboring land, which cannot be irrigated.

The Control of the Water Sources to rest with the Land-Owners.

There is nothing in political economy more wise, clear and unquestionable than that the State, or the owners of the land using the water, should own and control the water supply.

No body of people should ever be placed in a position subject to the will and caprice of a corporation in connection with anything so essential to their well-being as water. To subject them to this condition is only to entail a system of bondage or serfdom on them and their posterity. Unfortunately for California, many have occupied the legislative halls who could not see the importance of conserving the waters of the State to fertilize the lands. Others, of a worse character, have been bribed to legislate these lands into speculators' hands.

Perhaps there are no duties belonging to the Granger organization greater than the wresting of the waters of the State from the control of men who desire that farmers should pay them tribute forever. Even and exact justice will be done these men by condemning and confiscating their claims, and the paying to them the actual amount they have paid out and the value of their property at this time; no prospective value to be considered. This amount to be paid by the State, county or irrigating district.

Corporations not Needed to Supply Water.

Many persons believe that these plains will not be irrigated unless the work be done through a corporation or association of capitalists, and that it is therefore a necessity to surrender to them the control of the water supply. This alternative should not be accepted, because of public policy and the greater benefit which will ensue to land-holders by the owning and controlling of the water.

It is true that a large part of the land of these valleys is owned by speculators who bought with a view to selling at a profit, and they will therefore favor the project which gives them the most profit with the least expenditure. This condition of things we cannot alter, and must accept; nevertheless, the future demands that works of irrigation be established, even though large land-holders become enriched, for we must have comfortable homes for the millions who seek to live in California.

The question how to frame a law of association so that the ownership of the water and the land may go together, should be considered by every politician in the State, and no candidate for legislative office should be considered competent until he presents to his

constituents the draft of a law covering land and water ownership.

How District Association Reclaims Overflowed Land.

We have found that by association lands may be reclaimed from overflow, why, by the application of similar laws, may not lands be irrigated?

To the question, why has not reclamation been more successful, the answer is, California engineers have tried to exclude water from lands by building levees of turf and spongy soil upon land which floats on a bed of mud and water. The most insane engineer in existence will still retain sense enough to tell you that the first rule of leveeing is to ditch through the turf, and then get solid earth from the bottom of the river by dredging machines, or earth containing no vegetation from the nearest practicable place, and to base the levee upon the hard pan or solid earth beneath; for levees, as buildings, require unyielding foundations.

The law of 1868 sets forth that the owners of a majority of the land in any district may associate and then elect trustees. These trustees may employ engineers to make plans and estimate the cost of the work necessary to reclamation. Upon these plans and estimates the Board of Supervisors, if they approve them, direct three commissioners to jointly view the land, and assess upon each and every acre to be reclaimed or benefited thereby, a tax proportionate to the whole expense, and to the benefits which will result from such work; said tax to be collected and paid into the county treasury, and shall be paid out for works of reclamation, upon the order of the Board of Trustees, when approved by the Board of Supervisors. This tax is enforced by the District Attorney of the county in a manner similar to the enforcement of the collection of State and county taxes. With a few amendments the reclamation laws are sufficient to reclaim the lands and keep the control and ownership of the levees within the hands of the owners of the land.

Some of the Legislation Necessary to the Formation of Irrigating Districts.

Two incomplete and inefficient acts were passed upon irrigation at the last session of the Legislature. These acts may be so altered and amended as to render irrigation by association entirely practicable. The legislation needed should cover the following points:

1st. The Surveyor-General of the State should lay off the land of the State with reference to irrigation, and set forth the proper water supply to each district and the place and manner of taking it.

2d. The owners of a majority of land susceptible of irrigation should be enabled to form a district.

3d. Trustees should be elected by the owners of the majority of the land in the district.

4th. Trustees shall apply to the Surveyor-General of the State to designate the water supply proper to the district, and the land outside of the district necessary for canals or other work. As soon as the land and water is thus designated, the trustees shall immediately take possession of the same and hold them as property of the district.

The trustees shall employ an engineer to make plans, surveys and estimates of the works necessary to irrigation.

5th. The Attorney General of the State shall immediately seize, condemn, and appropriate such water and land as the Surveyor General shall designate as necessary to the district, when the owners of such water sources or land shall establish in court the amount they have actually expended in works connected with such water supply or land, and the actual value at the time of seizure, without reference to any future or prospective value. Then the trustees of the district, approved by the Board of Supervisors, may order the amount paid out of funds belonging to the district. But no prospective damages to the owners of water or land shall be allowed by the courts or paid by order of the trustees. The appropriation of the water and land should be immediate and irrevocable; the litigation for damages may take place afterwards.

6th. To furnish the money necessary to works of irrigation, there should be commissioners appointed by the Board of Supervisors, or, when in two or more counties, by the joint action of the Supervisors of the counties; these commissioners to assess upon each and every acre a tax proportionate to the whole expense as estimated by the engineers employed by the trustees, and to the benefits, either directly or indirectly, which will result from such works.

7th. These assessments to be collected by the District Attorney of the county in which the land lies, or by some State officer appointed for the purpose, and the amount collected to be immediately paid into the county treasury and there subject to the order of the trustees when appointed by the Supervisors. But no order to be paid except for work actually done or in compliance with the judgment and orders of a court. Warrants drawn by the trustees to draw interest at 10 per cent. per annum until paid.

8th. Assessment to the full amount necessary should be made by the commissioners upon the estimates formed by the engineers employed by the trustees of the district; but the trustees shall call in only installments of this tax large enough to cover the works which must be completed within six months from date of call. All assessments to be a lien upon the land and work its forfeiture unless paid.

9th. All contracts to be let to the lowest

bidder for cash, and all contracts to be let in small sections, after due advertisement. Thus giving the poor man an opportunity of paying his assessment by his own labor.

10th. The district thus formed shall own the water forever, and no land not included in the district, and which has not paid for the works of irrigation at the time the works are constructed, shall have the use of this water, except on such terms as the officers of the district may dictate; for the land owner who will not assist in the enterprise should have none of its privileges.

State Credit as an Assistant.

As the irrigation of these plains is of great importance to the State, it would be well to consider whether the loan of the credit of the State would be proper. If it is proper, then the owners of the land should pay interest in advance, so that the State shall lose nothing by delay; and the failure to pay interest should work an immediate forfeiture of the land in every case. No loan of State credit unless based upon the certain and absolute forfeiture of the land, upon the failure to pay the interest or any part of the principal on the day designated; and for this purpose the owners of each tract should obligate themselves by land when forming the district, or before availing themselves of State credit.

In order to avoid hasty or improper disposition of State bonds, they should be sold by the officers of the State and not be sold for less price than the market value of other State securities. This and the letting of all work to the lowest bids for cash may tend to insure an honest action on the part of trustees.

State Ownership of Canals.

If the State should actually own and build canals for irrigation, canal rings, as in New York, may be formed. And if it is proper to construct them in one place, why not in fifty places? The owners of gravel and placer claims will not understand why the land speculator should have State bonds to assist him, when other great interests of the State require assistance. The title land owner will equally demand assistance, and thus, when the State begins to issue bonds, who can tell the stopping place?

State Aid Not Necessary.

Few farmers on these plains count their acres by less than hundreds, and speculators count by thousands. If they form districts and prove to the world that they intend to irrigate, their lands will rapidly advance in value, and thus before they have to pay their first assessment they can sell one-half their land for enough to pay for irrigating the other half. Now, as one acre irrigated is worth ten not irrigated, it seems a fair proposition that they should, if necessary, sell a portion to improve the other. State aid, except to assist in the formation of districts and the condemning to their use the waters of the rivers, should not be extended to the owners of the land.

The entangling alliance of State with land sharks will be fruitful of no public good. As almost all have more land than they can properly work after irrigation, let them sell a part to enhance the value of the remainder.

An Appeal to the Legal Fraternity.

Let it be understood by all who read this article that it is written for the purpose of urging men of legislative capacity to frame an effective law upon a most difficult subject, as the above is but a crude and unfinished sketch.

How to wrest from the water grabbers the waters of the State will puzzle many able men and the legislator who can frame an act to do so should be well appreciated by his fellow men. It may save much trouble in the Legislature, and enable our law makers to approach the subject with more intelligence if some of the legal minds of the State would publish in the journals of the day the outline or draft of a law applicable to the case, for no hasty legislation can properly encompass the great questions involved.

DR. M. W. RYAN.

CHEERY CREEK.—A correspondent of the White Pine News writes: The Star mine still remains a luminary of the first magnitude. We understand that the Superintendent, M. Keeney, has contracted with the San Jose company at Egan for the use of ten stamps for the ensuing month to run on Star ore; this is in consequence of the five-stamp mill, which has constantly been at work on ore from the mine, not being able to keep the dumps clear. With the milling facilities thus employed the will be able to reduce 15 or 20 tons of ore daily producing in billion over \$100 per ton, aggregating \$1,500 to \$2,000 per day. This ore produced from a mine only partially opened and which will eventually quadruple the amount. In the last four months this camp has shipped about \$85,000 in bullion, produced from 900 tons of ore. The Exchange will commence milling ore next month. The appearance of the mine warrants the prediction that, once started, this company will run its mill indefinitely and profitably, adding largely to our bullion products. The Chan is bonded to parties who own other valuable property here. It is thought that work will soon be resumed under the new management and that it will prove to be what it once promised—the convey of the district.

The new Belcher air shaft is about timber and finished down to the 1000-foot level, is greatly benefiting the circulation of air the lower levels. The mills are kept steadily running on ore from the mine, and everything looks prosperous for the future.

MECHANICAL PROGRESS.

Testing Iron and Steel.

With the exception of these experiments made some two years ago by Col. Eads in connection with the construction of the St. Louis bridge—such experiments were noted in these columns at the time—very little has been done in the direction of testing the tensile strength of large masses of iron or steel. The method of testing heretofore employed has been the adoption, as a standard of unit, the results given by the extreme proofs of specimens having a section of about one square inch, from which the strength of large masses is obtained by theoretical formulae—qualified by the introduction, as a factor of safety, of four-fifths of the result, which is thrown away for possible errors, lack of homogeneity, poor workmanship, etc. Practice has found it necessary that this great margin should be allowed when dealing with large masses. Col. Eads' experiments so fully verified the necessity for such allowance. That so great a discrepancy between the calculated and actual results as four-fifths could be found necessary, has led many engineers to the conclusion that a new theory is necessary for the estimation of the strength of iron. It is held by such that a series of careful testing experiments with large masses of various diameters should be instituted, in order to detect the unknown cause of the remarkable variations noticed between the theoretical estimates and actual results.

The experiments of Col. Eads have led to a new discussion of this matter, and have developed some unexpected results with regard to this comparative tensile strength of iron and steel, when presented in large masses. A universal was the confidence in steel over iron, that in the inception of his great bridge enterprise it was decided that only the minor parts of the bridge should be constructed of iron, while steel should be the material for the more important parts. Being one of those who had contracted a strong doubt with regard to the reliability of experiments with small masses, resolved, in order to insure undoubted success in his great life monument, to subject every portion of the structure to practical tests. This ended an enormous hydraulic testing apparatus was constructed.

The first heavy pieces subjected to this test were a large number of massive iron shafts, which stood up well to the theoretical test. But most unexpected failure was experienced in testing the steel shafts, from which so much better results were expected. Some of them gave way under strains which iron shafts of similar dimensions had endured. A much larger discrepancy was found to exist between the large and small masses of steel than between similar masses of iron. So great was this discrepancy that the steel shafts were at once condemned and iron substituted wherever heavy masses were required.

This showing may well call in question the propriety of using steel in large masses where ultimate strength is brought into play, notwithstanding its acknowledged superiority for such uses in small masses.

We believe these are the first and only testing experiments which have been made with steel under such conditions. A practical comparison was made with the two metals some years ago on board the steamer *Red Jacket*, in which two shafts of equal size were placed, one of iron and the other steel. The steel shaft lasted off within a week, while the iron was in service up to the present time.

What the nature of this difficulty with steel in large masses may be, is quite unknown, but the facts are notorious. Krupp has for this reason abandoned his solid forged steel cannon. The matter is very naturally exciting much enquiry and speculation, and cannot fail to add materially to the interest which will be taken by engineers everywhere in the result of the Government experiments which are about to be undertaken in accordance with an act of Congress passed just at the close of the last session, full reference to which will be found elsewhere on this page under the head of "Test of American Iron and Steel."

PRESERVING CAST-IRON FROM RUST.—Girders, angle irons, and other similar large masses of iron are often placed in exposed positions, where damp, air, steam, and acid vapors have access. If the iron be put up in a rough, it very speedily rusts, and under working conditions the corrosion soon reaches a dangerous point. Contractors generally care to supply such irons painted in three coats of minium, which, if honestly done, would to a certain extent protect the metal; but, as a rule, only one thin coat is applied, and the slightest abrasion exposes the iron. A new and peculiar mode of treating iron is the following: the metal is heated until, if touched with oil or fat, it fizzes, and then is plunged into a vat of mixed oil and grease. This mode of treating cast iron is therefore far superior to any "painting," as the oleaginous matter actually penetrates the pores, and prevents oxidation for a very long time, while it does prevent painting, if desirable, afterward.

Test of American Iron and Steel.

The Sandy Civil Appropriation bill, passed among the last acts of the late Congress, contained an appropriation of \$75,000 for tests of iron and steel, to be made by a Board of Engineers, who are to serve without pay, with the exception of the Secretary. The members of this Board have recently been appointed by the Secretary of War, as follows: Colonel T. T. S. Laidley, Ordnance Department, U. S. A., resident; Professor R. H. Thurston, Secretary; Commander L. A. Beardslee, U. S. N.; General Q. A. Gilmors, Engineer Department, U. S. A.; Chief Engineer David Smith, U. S. N.; W. L. L. Smith, C. E.; A. L. Holley, C. E. A testing machine is to be built, and set up at the Watertown arsenal, where the experiments are to be conducted. The Board will receive instructions from, and report to the Chief of the Ordnance Department of the Army.

The members of this Board are all well known engineers, several of whom have already distinguished themselves by their investigations of the properties of materials used in construction. It would be difficult to over-estimate the value of their future experiments, if carefully conducted. To mention a single instance, it may be stated that the English formula deduced from Gordon's experiments is almost the only authority available to our engineers for computing the resistance of materials to compressive strains. Very few of our engineers could afford to make such experiments as they desired; and when such investigations were conducted by companies, the results were not usually available for general use. It seems probable, therefore, that the appropriation, made by Congress for these experiments, will be productive of more good than many other items for which ten times the amount was allotted.

ABSENCE OF OXYGEN FROM ARTESIAN WATER.—M. Gerardin, in a paper read to the Paris Academy of Sciences descriptive of the artesian wells of Grenelle, finds there is no oxygen present in the water from the lower sandstone of this locality, nor from the Rilly gravel beneath the clay and at contact with the chalk (the water was obtained out of contact with air from various depths by means of a syphon invented by the author), nor from the Soissonais gravel. Neither was this gas discovered in the water from the artesian well at Gonesse. M. Gerardin concludes that water obtained from subterranean depths does not contain oxygen if kept from contact with the atmosphere. This precaution is essential, for in contact with the air it dissolves several cubic centimetres of oxygen. The author has often found in the interior of the ascension tubes long whitish opaline filamentary algae. These algae present the curious property that they remain whitish in solar light as long as the water is deprived of oxygen, but they become green the instant the water is the least aerated. Their sensibility to the action of oxygen is most delicate. The action of the algae serves to confirm the chemical test with hyposulphite of soda.

It might be interesting to have these experiments repeated on the water from California artesian wells. It is well known that aerated water readily parts with its oxygen when thrown into the atmosphere in the form of a fine spray, as has been evinced in recent experiments of renewing the oxygen of the atmosphere in diving bells by this means alone—direct connection between the atmosphere and the bells being entirely cut off for hours without any inconvenience to the occupants. Probably the filtering of the water of artesian wells through the large extents of earth and gravel through which it generally passes before reaching its subterranean reservoirs produces the same results as the spray.

A NEW HEATING FURNACE.—A new invention has recently been made by Messrs. C. Reese, master mason, and Thomas Johns, superintendent of the mill of the iron and steel company, at Ironton, Ohio. The improvement is practically a double furnace, having a grate at both ends, with the fire in the center, passing down between the two doors under the body of the furnace into the chimney on the other side. The inventors claim that this furnace will do one-half more work, for the reason that the heater can be charging at one door whilst drawing at the other; and that it will save largely in iron from the fact that the cold air passes directly to the fire before reaching the iron; that it will save greatly in coal, there not being so large a surface to be heated as in the ordinary furnaces; and further, that it costs less to build and less labor to work it, doing away with the labor of pulling the fine piles to the bridge for sufficient heat, the last pile charged being the first ready to draw out. The furnace is said to be well suited to rail, bar, plate, guide and hoop mills. It is believed by practical iron workers that this furnace will prove to be an important addition to the productive capacity of rolling mills. There will be one of them put in the mill of the above mentioned company as soon as possible.

IRON IN THE CENTENNIAL BUILDINGS.—The quantity of iron to be used in the construction of the Centennial buildings will aggregate about six thousand tons, of which more than five-sixths will be wrought.

The Pullman palace car company are making, at their shops in Detroit, eleven palace cars to go to England and nine to go to Italy.

NEW MODE OF TREATING BELTS.—A correspondent of the *Scientific American* writes as follows: I have for the last 25 years, on every Saturday evening, turned the inner side of my engine belt outside, let the engine run slow, and washed the belt well with warm water and soda, applied with cotton waste. Next, I take a piece of sheet metal and scrape well the belt, next wash with clean warm water, and dry off. I collect the waste oil from this shafting and apply to the belt as much of it as possible. This washing must be done as quickly as possible so as not to dissolve the glued parts. I let the belt stand on the pulleys till Monday, then give another scraping and turn the belt as before. I keep the pulleys very clean. I have long been surprised at this economy I have effected with very little trouble. I have not bought a new belt for the last ten years. There is an engine next me, 14x36 inches (mine is 12x36). I have nearly double the shafting and belts, and my neighbor cannot run with less than 38 lbs. of steam when all the belts are on the loose pulleys. Mine will run at full speed with 5 lbs.

These suggestions, adds our correspondent, will be appreciated by our readers. One must begin with a first class belt, made in the best manner, and use considerable judgment, in following the practice of our correspondent.

SCIENTIFIC PROGRESS.

Effect of Temperature upon the St. Louis Bridge.

The effect of changes of temperature upon iron structures is most palpably demonstrated in the case of the bridge recently constructed over the Mississippi, at St. Louis. The arches of this bridge have spans of about 500 feet, and careful observations of the changes in the height of these arches have been made daily during the months which have elapsed since the bridge was completed up to January. These observations show a variation between the figures of July 20th and January 9th last—which two days were the warmest and coldest of the year—of 8.5 inches. The difference in temperature between the two days was 107 degrees. This is an effect less than was anticipated, the small effect being due to the fact that the iron work is painted white for the very purpose of lessening the same.

It has also been noticed that this change is not always coincident with the showing of the thermometer, the result being varied at the same temperature, by reason of the greater or less amount of moisture in the atmosphere.

The effects of change of temperature are, at the present day, says the *Railway World*, taken into account in all engineering calculations. They determine the distance between the ends of the metals on a railroad track; necessitate the use of rollers at the end of bridge trusses when the variation in their length, produced by rise or fall of temperature, is perceptible; require the use of expansion joints in long iron gutters and the hot air pipes of a blast furnace, and have driven civil engineers at times almost to their wit's end for "compensating" contrivances.

During the erection of Southwark bridge across the Thames, at London, the structure was almost ruined for want of observing this natural law, the expansion of the cast iron of the arches under the sun's rays producing a strain upon the piers which had not entered into the engineer's calculations.

Since that time bridges have been more carefully framed with respect to thermal influences. The engineer's endeavor is to have the expansion or contraction of one part counteract the corresponding change in another part, so as to increase the stability of the whole.

PARASITES ON FLIES.—A correspondent of the *Scientific American* says that while recently examining the tongues of the house fly with a microscope he discovered upon several species of worm. On some he found two worms, on others none at all. The worms were found about the spiral glands; they were transparent in appearance—head and tail being exactly alike. They were very active in their motions. The correspondent is desirous to know from other microscopists if these worms have been noticed before, and would be pleased to receive any information concerning them.

Have any of our San Francisco microscopists noticed them? If they have we should be pleased to hear from them. If they have not they might perhaps find the house fly an interesting subject for observation, who will verify, or otherwise, both the above and the observations minutely detailed in the issue of the *Scientific Press* of April 27th with regard to this insect.

THE ANDES GRADUALLY SINKING.—The highest points of the Andes are thought to be sinking. In 1745, when measured by La Condamine, Quito was found to be 9596 feet above the sea. In 1803 Humboldt made it 9570 feet, in 1831 Boussingault 9567 feet, in 1867 Orton 9520, and in 1870 Reiss and Stübel 9356 feet. If the earliest and latest measurements were exact Quito has sunk 240 feet in 125 years.

SINGULAR FACT IN REGARD TO DRIFTING ICE.—Lieut. Weyprecht, of the late Austrian polar expedition, made this remarkable discovery that the ice never drifted straight in the direction of the wind, but that it always deviated to the right, when looking from the center of the compass. With N. E. wind it drifts due W. instead of S. W.; with S. W. wind it drifts due E. instead of N. E.; in the same manner it drifts to the north with S. E. wind, and to the south with N. W. wind. There was no exception to this rule, which cannot be explained by currents, nor by the influence of the coasts, as with these causes there would be opposite results with opposite winds. Another interesting phenomenon was the struggle between the cold northern winds and the warmer southern ones in January, just before the beginning of the lasting and severe cold; the warm S. and S. W. winds always brought great masses of snow and produced a rise in the temperatures amounting to 76-95 degrees Fah. within a few hours.

The influence of extremely low temperatures upon the human body has often been exaggerated. There are tales of difficulty in breathing, etc., that are caused by them. Lieutenant Weyprecht and his party did not notice anything of the kind; and although many of them had been born in southern climes, they all bore the cold very easily indeed; there were sailors among them who never wore fur. The cold only gets unbearable when wind is united to it.

RELATIONS BETWEEN MAGNETISM AND THE AURORA.—It appears from the scientific report of the Austro-Hungarian North Polar expedition of 1872-4 that magnetic disturbances are closely connected with the aurora. While in temperate zones they are the exception, they form the rule in arctic regions; at least the instruments are almost in constant action. This is the case for the inclination, declination, and intensity needles. The magnetic disturbances in the district visited were of extraordinary frequency and magnitude. They were closely connected with the aurora borealis, the disturbances being the greater, the quicker and the more convulsive the motion of the rays of the aurora, and the more intense the prismatic colors. Quiet and regular arcs, without motion of light or radiation, exercised almost no influence upon the needles. With all disturbances the declination needle moved toward the east, and the horizontal intensity decreased, while the inclination increased. Movements in an opposite sense, which were very rare, can only be looked upon as movements of reaction. The ways and manner of the magnetic disturbances are highly interesting. While all other natural phenomena become apparent to our senses, be it to the eye, ear, or touch, this colossal natural force only shows itself by these scientific observations, and has something mysterious and fascinating on account of its effects and phenomena being generally quite hidden from our direct perception.

ORIGIN AND PHILOSOPHY OF LIMESTONE CAVES.—Caves in limestone have usually had their origin in fissures, through which water flows, or at one time flowed, at first slowly percolating through them, and then, as they gradually became larger and larger the volume of water likewise increased, until the fissure became converted into a true underground river or water course; even in cases where no water flows through them at the present day it can plainly be seen that such was the case once.

They are eaten out of the limestone by the solvent power which water charged with carbonic acid possesses. Ordinary water free from carbonic acid would be quite incapable of dissolving out the limestone, but all natural waters contain more or less of that gas, derived by the rain from the atmosphere and from the decaying vegetable matter which it meets with in its passage through the soil. All limestone caves usually retain more or less completely their original form of fissures, expanded, perhaps, in parts, into vast caves and chambers of immense proportions, but again contracting a little further on into a mere crack or tunnel. Comparatively large rivers are received by such caves, which then continue their course underground, in some cases suddenly appearing to the light of day again, but in others making their way beneath the surface right out to sea. Certain of the South Australian creeks are thus discharged.

PHOSPHOROUS AND PUTREFACTION.—The presence of phosphorus or some one of its compounds has been observed to be one necessary condition for the development of putrefaction. The more phosphorous the more rapid the putrefaction. The bad odor is supposed to be owing to the escape of phosphoretted hydrogen, and to the same compound is attributed the luminosity of putrescent matter under some circumstances. On passing the gases evolved from putrefying matter through argentic nitrate, no phosphorous compound of silver was found, although the gases were completely deodorized by passage through the silver solution.

SCIENCE AND INDUSTRY.—An interesting example of the industries and important results which have sprung recently from the scientific treatment of substances long overlooked or unnoticed, is that afforded by the silky vegetable down which clothe the seeds of many trees. These are now largely employed in some parts of the country for stuffing beds, quilts—in the place of eider down—also ladies' skirts, and for other purposes.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

GOVER MINE.—Amador Ledger, May 1: This mine is fast being developed into a valuable mining property. A 10-stamp mill, driven by water from the Purinton ditch, is now in active operation, and crushing good grade ore. The ledge in the 700-ft level averages from eight to ten ft in thickness, and the ore of high grade, bearing free gold, and well charged with gold bearing sulphurets. Drifts have been run north and south from the main shaft, and the ore found to increase in quantity and quality in all the levels. Between 1000 and 2000 pounds of sulphurets are saved from each day's crushing, and which yields at the rate of \$200 per ton. The Gover is not only looking remarkably well, but may be classed with the valuable mines of the county, and this result has been brought about under the excellent management of Mr. John Treglaon, a careful and experienced miner. The mill is under the supervision of J. R. Treglaon, a practical millman. Hendy's concentrators are used and give entire satisfaction. Hooper's steam pump is attached for freeing the mine of water. The Gover company are likewise owners of the Fremont mine in the same neighborhood, and we learn will in a short time commence sinking a shaft thereon, with the intent of proving the mine as rapidly as possible.

BUTTE.

LAVA BED MINING.—Oroville Mercury, April 30: Mining at the Lava Beds has started up with more than increased alacrity. The long dry winter has left the claims free from water, so that they can be worked without much trouble. George Dyer is at work for the Hilton company, with every prospect of success, though it will take some time yet to get ready to take out pay dirt. On Monday last we saw Mr. Bigelow at work putting up a steam engine on the claim of Ah Hap & Co. It was what is known as a Hooker water lifter. There is little doubt that all land now vacant will soon be settled for. A great call will be made for poles, wood and building lumber during the coming summer. With the increase in the work carried on there will be a corresponding increase in trade in town. Money, even now, is plenty.

CHROME.—M. Robinson, of Nimeshew, in this county, came to town a few days ago, having some very black rock which he wished to have tested. Mr. Oallow, our county clerk, sent it to San Francisco to an eminent assayer. It turns out to be chrome iron and runs as high as 60 per cent. pure metal. There is an abundance of the ore in sight, and it is very easily gotten out. The mine is twelve miles from Chico, on a down-hill road all the way. Two claims have been taken up. The ledge is from 10 to 20 feet wide.

THE NEW MILL.—At last the new quartz mill at Forbestown is finished, and has been running just five days on trial, and turned out \$500, or just \$100 per day, with blanket washings and sulphurets to hear from yet. The machinery is all new and works, as all new machinery does, with some considerable friction; still, we think this a pretty good showing for a beginning. The ledge is twenty feet in width and prospects \$30 to the ton. The rock is easily got out, and is only 200 feet from the mill and all the way down hill. The shaft is only down some 30 feet. The mill is now running night and day and is working as well as the owners could wish. The cost of taking out the rock and crushing it, of quicksilver and every expense, does not reach one-fourth the receipts.

CALAVERAS.

GWIN MINE.—Calaveras Chronicle, May 1: News from the Gwin mine continues wholly favorable. The 1000-ft level is run a distance of two hundred feet from the shaft, all the way in fair milling ore. Stopping is going briskly forward in both the 900 and 1000-ft levels. The batteries—forty-four stamps—are kept at work without cessation, and the yield of the mine is increasing from month to month.

RICH QUARTZ.—Rock of extraordinary richness is being taken from the well known Haskins and Hadley mine at West Point. The last crushing of quartz taken from the mine paid nearly \$200 per ton, and we are informed that the rock now being taken out will yield considerably in excess of that amount. The work of taking out rock is going steadily forward, and another crushing will be in readiness for the mill in a short time. The shaft on the ledge has reached a depth of about one hundred and forty ft.

FAVORABLE PROSPECTS.—Charles Rickman, proprietor of one of the quartz lead lately discovered at Mosquito gulch, is confident of developing a good mine. He has sunk a shaft about twenty-five ft deep on the ledge, taking out first-class ore from the top down. The lead is from fourteen inches to two ft wide and all the rock will pay well for crushing. Rickman is pushing work along as fast as his limited appliances will permit.

ASBESTOS.—A man named Hipkins has lately discovered a vein of asbestos in this county near Gibson's ranch, on the road from Angels to Milton. We have not learned the extent of the deposit, nor whether any considerable amount of work has yet been done upon it.

WEST POINT DISTRICT.—Last Monday the

new hoisting works of the Josephins were completed, and sinking the main shaft some thirty ft in depth was resumed. The new working shaft on the "Chesuo" is going down rapidly. A too heavy flow of water has interrupted sinking at the Modoc. Nothing new at the Anderson Flat mine. Stopping good ore at the Lone Star. The old Doyle mine is being re-opened by M. Carey, who is erecting steam hoisting works. The mine ranks No. 1 for high grade ore and uniform net results. Rich galeua ore has been struck in the north level of the Ramcat. A shaft is being sunk on the new discovery by Henry & Son. The ore will average one ft in width and mill about \$45 per ton. Champion, stopping. Ore richer than previous. This rich body of ore has lengthened from ten or twelve ft to thirty-five ft at a depth of 140 ft.

INYO.

PANAMINT ITEMS.—THE STETEFELDT FURNACE. Panamint News, April 27: Seator Stewart and party arrived in San Francisco on Sunday evening, and early on Monday morning they sent for Prof. Stetefeldt. He soon arrived at the company's office, and within two hours the contract for the furnace for the twenty-stamp mill was closed. Capt. Bell went immediately to work shipping the machinery, and the greater part of it is now on the way via the Allen's Camp route. The probabilities are strong that a furnace will also be put in the lower mill and its capacity increased.

JESSIE MAX.—Are progressing rapidly, owing to the softness of the ground. The shaft is down sixty feet and is in ore of a high grade. The width of the lead at the bottom of the shaft is not known, as no cross-cut has been run as yet to ascertain its extent. The tunnel is in eighty feet, and the last few feet is entirely in quartz carrying considerable chlorides, worth probably \$40 or \$50 per ton. This, however, is an unexpected find, as the ledge for which the tunnel is being run is yet some seventy or eighty feet distant.

DON JUAN.—They are timbering and stopping out ore for shipment to San Francisco. The first shipment of twenty-five sacks of ore by this company was made on the 23d inst., and they have ten or twelve tons more ready to ship as soon as out-going trains can be had.

EMMA.—The Emma joins the Sunrise on the northeast, being east of the Twilight. The ledge has been stripped for about eighty feet. The mine is looking extremely well, some two hundred tons of ore being in sight, which is of the free milling character.

WYOMING.—In the lower tunnel, which was being run to tap the main ledge, the vein was struck in running one hundred and fifty feet, striking it at a depth of about three hundred feet. They are now in a fine body of high grade ore, but the extent of the vein has not yet been determined.

LEE DISTRICT.—Captain J. B. Frink gives us further information concerning Lee district, which was organized a few weeks ago. This district is twenty-five miles from Panamint and fifteen from Cerro Gordo, on a direct line between the two places. There are about twenty locations made in all, in a space of about half a mile square, all by San Bernardino men, comprising two companies. The first company is composed of J. R. Frank, B. L. Lee and Henry Clark, men who have been prospecting between this point and the Colorado river for a number of years, and are the discoverers of this district. The other company consists of fourteen persons, among whom are General Dodge of San Francisco, Rose, of Los Angeles, and Watson and Walsh. These mines are exceedingly rich and crop out from 2500 to 4000 feet in length. They are situated upon a high mesa, about 5000 feet above the level of the sea, wood and water are abundant and about six miles from the mines, a good level road leading thereto.

KERN.

ANTIMONY.—Bakersfield Southern Californian, April 29: The Temple antimony mine, in San Emidio canon, is being opened, and furnaces are soon to be erected to reduce the ore to a condition for shipment to England for further refinement. Mr. Quinn, an old prospector, who has spent several years in the San Emidio mountains, hunting for mines, has consolidated his interests with the Temple company, and is still looking for more ground. An advantage to this mine of antimony—which is represented to be the purest discovered in this country—is the finding of a well defined lead of borax in the vicinity. This bed of borax is located high up in the mountains, and presents a fine bank, the extent of which is yet unknown. It is of the fine, velvety, snowball character of borax.

MARIPOSA.

THE TUNNEL AT BENTON MILLS.—Mariposa Gazette, May 1: The "high ore," commenced about two years ago, and upon which operations were for several months suspended, has been recommenced, with some improvements in the machinery. The tunnel is now in about 700 ft, and everything works smoothly. Mr. Horn, the former superintendent of the job, still runs the machine. The Burleigh drill walks into the solid ledge at a rate astonishing to an old miner, or any other man whose practical knowledge of drilling is confined to the old sledge and hand drill process. The question of striking good pay ore is only one of time. Everybody familiar with the Josephine and Pine Tree mines knows that the gold is there.

NEVADA.

OMAHA MINE.—Grass Valley Union, April 30:

Very fine rock continues to come out of the lower level of the Omaha mine. The ledge is 2½ ft in thickness, and scarcely any of the quartz taken out but shows free gold and fine sulphurets. Some fifty loads of rock have been put upon the dump within the past week, and experienced judges of quartz say it is the best looking pile of rock, taking it all through, that they have ever seen. Yesterday we saw a handsome piece of rock from the lower level, (240 feet), which showed free gold in the hard quartz, gold in the sulphurets, and had plenty of galeua. The Omaha company have it in consideration, owing to their excellent prospects, to erect steam hoisting works as well as a mill upon the mine.

BUCKHAM MINE.—This mine is located southwest of Grass Valley, near Bear river. The location was made years ago and the ledge has been worked with good success. The rock had to be hauled to Grass Valley in order to have it tested, and it has been worked through two or three different mills, in different lots. The ore has paid all the way from \$15 to \$29 per ton by mill process, and without estimating the sulphurets. The average of all the ore worked has been something over \$20 a ton. The ledge averages over 2 ft in thickness, and has been tested to a depth of 97 ft. A letter from J. G. Worthington, received yesterday from the Buckham mine, states that the rock is improving rapidly in the shaft, showing free gold (a thing that has seldom been seen in the rock which has been worked) and plenty of sulphurets. The mine only needs a mill on it to prove a success. This thing of hauling quartz from ten to fifteen miles is not economy. The owners are men without capital, and they would like to arrange for a mill. They can show the certified figures for the yield of the rock, and from the best and most careful millmen in this district.

New York Hill keeps sending out those rich specimens and piling up good pay rock on the dump. People here are beginning to talk about its being the richest mine in Grass Valley district, and when the works now near completion get to running, it will be apt to turn out net results which will substantiate this claim. New York Hill is "petering out" well.

MEADOW LAKE MINES.—Truckee Republican, April 28: We are able to state on authority that operations in this once well known mining district will be commenced on an extensive scale, just as soon as the snow is melted off so as to enable the parties who expect to operate them to get in their machinery and supplies. There exists no doubt of the richness of the ore found here, and the difficulty of working it at the former excitement, which was the only obstacle to making this district one of the richest in the State, has been removed. Two processes have been discovered which render the reduction of these rebellious ores no longer doubtful, and both of them are cheap and readily adapted to the work. One of them works the rocks up to the fire assay. Since the first of January upwards of fifty locations have been made, and many other parties are anxiously awaiting an opportunity to go in and make others.

The Culverson mining company has levied an assessment in order to prosecute the work of developing the mines immediately. The U. S. Grant company is now ready to begin work. Others that are not as yet incorporated are making active preparations to open their claims. A party of men left Truckee last night for this district, to look after some very rich claims. The party consisted of Frank Paulson, G. W. George Smith, Lee Butt, Wm. Hsler, David Hart, Robert Swin and others. They are all very sanguine of success. Some will remain to look after their interests and commence operations. There seems to be but little doubt that the past fame of this district will be eclipsed by the new fame it will soon gain, and we confidently hope to see this district one of the most important tributaries of this place, as supplies will probably be taken from here.

PLACER.

CLEAN-UP.—Placer Argus, May 1: The Indiana Hill canal, mill and mining company, located at Gold Run, cleaned up \$6,300 a few days ago from a three weeks' run. In the last three clean-ups, of six weeks running altogether, \$9,500 has been paid in dividends to the stockholders of the company.

CHROME.—Placer Herald, May 1: An extensive deposit of chrome iron has been discovered about five miles north of Auburn, on the old Grass Valley road, and is now being opened by a Mr. Martin. The ore, so far as tested, is said to be of a good quality, and is worth, say at San Francisco, in its crude state, about \$15 per ton.

PLUMAS.

THE NORTH FORK COUNTRY.—Plumas National, May 1: From Surveyor Keddie, who arrived in town from the North Fork on Friday, we learn that times are lively and that the season promises to be a brisk one. The Carriho hydraulic company have recently purchased the Fug & Ohl claims, which are located about one and a half miles above Carriho. The price paid was \$7,000, in coin. The ground prospects splendidly—in many places from fifteen to fifty cents to the pan. This will be the first claim opened by the new company. The operations of the Carriho company will commence as soon as the necessary supplies arrive from below. The Ditch hill pipe is working splendidly, and a good head of water has been running for about five weeks without a burst. There is every reason to think that

it will now stand the pressure. The mine at Barker hill is paying richly. After five days' run with one pipe they took up two lengths of poles at the head of the flums and got \$800 in fine gold—not a piece weighing over fifty cents. The ground-slice is from fifty to two hundred and fifty ft in length, and as many coarse pieces have been picked up in it, one weighing \$26.50, the probability is that the ground is very rich. The company propose to pump water by steam power to the top of Oummiag's hill, catch it in a reservoir, and use it for piping that ground. The water has to be raised from the ditch line 206 ft, and the pump at Ohio Valley will be used for the purpose. This ground is known to be immensely rich. They will commence work on this operation immediately, as Mr. Keddie has already made the necessary surveys. Messrs. Reed, Merwin, Bonte and Jacobs have recently been inspecting the Ditch hill operations, and were highly pleased with the prospects.

GREENVILLE NOTES.—Our dispatches from Greenville are up to April 30: The work on the Indian Valley mine, under the superintendence of Mr. O. Drake, is progressing rapidly and well. The fine rock struck just before the big cave took place is looking even better as developments continue. Everything promises well and the mill will be started next week. Mr. Purdy, the Superintendent of the Crescent mill's property, has arrived. He talks of starting up work again. The Hudson mine, with ample funds, will soon be started up by Mr. E. Leets. He proposes also to rebuild the Dixie mill. The Baker mine is looking splendidly. They are now getting good pay rock in the Union company's mine.

SANTA CRUZ.

BI-CARBONATE OF LIME.—Santa Cruz Sentinel, May 1: It has been known for some time that a valuable deposit of bi-carbonate of lime existed within Santa Cruz, on the western boundary of the town. Recently, Calvin Brown, engineer of the navy yard at Vallejo, visited this county in search of material to manufacture Roman cement, and found that abundance existed in our midst, in the vicinity of the grind-mill now leased by Messrs. Bennett & Hinds. He had once secured four acres of the land, quite sufficient for his present demands. The deposit is almost inexhaustible, underlying the lands of Mrs. Majors, Messrs. Pray, Towne, Doderer, Boston, Heath, Hitzelberger, Wright, Heacock, Kirby and others along the plateau from Kirby's tannery to the rocky cliffs adjacent to Mrs. Majors' residence, with a width nearly the same distance. The deposit crops out near the tannery, and at places is probably from twenty to fifty ft deep. Its value is beyond present computation, as no other similar deposit has yet been discovered in the United States. The manufacture of Roman or Portland cement will at once be commenced, and it is said that the old mill (Majors') will be used to grind the material after baking and mixing the ingredients. To make a good cement, a blue clay from the salt marshes near Benitoia will have to be procured and added to the carbonates of lime, and baked at a white heat in the proper kilns, and then to flour fineness, and put in close paper-lined barrels for market. The Croton aqueduct, the Delaware breakwater, and many other important public works throughout the country, were built with similar cement. The Sheppey stone of England from which Parker's cement is obtained, is more nearly like the stone discovered in Santa Cruz. It is not properly a stone, but an artificial (seemingly) hydraulic lime, composed of a mixture of clay and chalk which abounds along the coast, but only in this particular place has it the necessary amount in equal parts for the purposes of cement.

SIERRA.

PILING.—Mountain Messenger, May 1: The Green Mountain is still piling, nights.

A mining excitement prevails at Howland Flat, and claims are being rapidly taken up.

The Bald Mountain claim gets richer as the go into the mountain.

The Woodchuck ravine boys have all gone out to commence their spring's work.

The Swallow company, at Monte Cristo, is troubled with bad air.

"HOMESTAKE."—The Homestake quartz company, situated above Rock creek, has some thirty or forty ft of tunnel yet to run through hard bedrock before reaching their ledge. This is the ledge from which Johnson took \$3,000 with a hand mortar. If everything is satisfactory when the ledge is reached, the company will immediately erect a mill. The ledge is large, but is very rich.

The Oro company have put two shifts' work in their mine, to put it in better order for taking out quartz.

DISCOVERY.—"Slug Canon George" has discovered a quartz ledge in Slug canon that prospects well.

The trouble about water between the Bald Mountain and the South Fork companies has been settled.

STARTED.—The Keystone mill, which has been lying idle for several months, has again been started.

We are informed that work is to be commenced soon in the deep gravel mines and the ridge below Gibsonsville.

The Union company have found quite an extensive bed of pay gravel in the back of their claim at Gibsonsville.

NEW MILL.—The Independence quicksilver mining company are considering the propriety of putting in 20 new stamps. The mine said to be paying finely.

The Oak Ranch company will run their

ahead. Where they raised their shaft the rock was pitching and the gravel of the me quality as at Monte Cristo.

ONOMA.

Coal.—Petaluma *Argus*, April 30: Discovers indicating the existence of valuable deposits of coal have recently been made by E. Rathburn and L. E. Brooke, of this city, on a ledge of Thomas Hopper, about two miles west of his residence. The work of prospecting a mine will be commenced soon. Two or three other parties are prospecting for coal in Onoma mountain.

MINING.—Russian River *Flag*, April 1: The Sotoyome mine has two shifts working in one tunnel, and on last Friday struck large matter containing cinnabar, 96 feet from mouth of tunnel.

Just now the quicksilver business is very all in this county. The Excelsior has extended work; the Geyser furnace has stopped work, in order to increase its condensing capacity, and many claim-owners in the various mining districts have discharged their hands. Quicksilver at 60 cents a pound is not very inspiring.

Tax. Mt. Jackson has struck another fine vein of ore. The quality is the best we have ever seen from that mine.

Capt. C. A. Eastman informs us that the Anderson Jew mine (Sansal canon) is looking better than ever before. He has made arrangements for crushing six tons of ore at the Calistoga mill. The ore is to be shipped this week. Besides, he is bagging some more rock, to be shipped to San Francisco.

Tak Calistoga silver mine cleaned up \$9,540, a day's run, week before last.

COLUMBIA.

COLUMBIA.—*Union Democrat*, May 1: Last week at a depth of eight hundred feet in the south end of this mine, a fine vein of rich quartz was found. It is reported to be as rich as the ore which gave prominence to the mine the day of its great prosperity. The south end has never been worked, and should this result find proof to be as represented, it may be asked for the "Sonsby" to take rank again with the large paying mines of the State.

MAKES & DABROW QUARTZ MINING COMPANY.—*Union Independent*, May 1: The Fisher No. 6, which is the new hoisting shaft, is now at some sixty feet, which is equal to 130 ft below Nos. 3 and 4. A small shipment of ore was made on Monday last, which yielded, mill process, nearly \$300 per ton. This new shaft has cut in its vertical course the very rich feeders, all tending to the main vein, which dips into the hill at an angle of 27 degrees. When the depth of 100 feet shall have been obtained, a drift to the ledge will be made and a level connecting with Nos. 2, 3 and 4, and an upraise made to the two latter, of only 200 feet, and which will be the first drift or level ever run in the mine. The ore (some 480 tons on the dumps) having all been taken from the several prospecting shafts north and south in merely sinking an incline—following the ledge. Having prospected the mine fairly, the more expensive work of a full hoisting or working shaft has recently commenced, with an increased force, and improving the continuity of the ledge to the extreme north.

Nevada.

ASHOE DISTRICT.

CONS. VIRGINIA.—*Gold Hill News*, April 29: Daily yield, 500 tons of ore, keeping the mills running up to their full working capacity. The ore breasts and stopes on the 1500, 1400 and 1300-ft levels are all looking well and yielding the usual amount of rich ore. The joint cross-cut on the 1400-ft level is still driven vigorously ahead in the ore vein, the quartz ore being of fine favorable character. The east cross-cut on the 1200-ft level, at the edge of the ore vein, and is showing some streaks and spots of excellent ore.

CALIFORNIA.—The enlargement of the main drift on the 1500-ft level for a large air shaft to connect with the Ophir mine and to secure the thorough ventilation of the level, is making steady and favorable progress. Cross-cut No. 3 on the 1500-ft level is still driven forward through the ore vein, the face in low ledge ore. The face of cross-cut Nos. 4 and 5 on this level are still in good ore, as is also that the north and south drift running in the ore vein to connect cross-cuts Nos. 3 and 4. The joint cross-cut on both the 1300 and 1400-ft levels are energetically carried forward, that on the 1400-ft level being in the ore vein, and the other being just on the point of entering it. Making the winze from the 1400 to connect with the 1500-ft level is making good progress. The bottom still in ore.

OPHIR.—The ore stopes on the 1465-ft level continue to look well. The face of both the east and west cross-drifts from the northeast drift, at the bottom of the north winze, on the 10-ft level, are still in a fine character of ore. **BULLION.**—The east cross-cut from the north drift, on the 1700-ft level of the Imperial mine, the ledge day before yesterday, which shows the fine ore prospects, and although nothing can be fully determined in a mine until the developments are completed, there seems hardly doubt any more but that the Bullion is going to develop into a paying mine.

SAVANNAH POINT.—Daily yield, 500 tons of ore. The ore breasts are all looking well and promise a good yield for a long time yet to come. Prospecting the ledge at the 1600-ft level has developed nothing new during the week. Driving main east drift on the 1700-ft level is making good progress.

CALEDONIA.—The new shaft is now down and thoroughly timbered to the depth of 115 feet. The erection of the new air compressor is about completed. As soon as the compressor is ready to run, a six inch pump will be attached for the purpose of extracting and keeping down the water in the shaft.

BEZUCHKA.—The water is being rapidly extracted from the main incline, although nearly 100 ft in depth yet remains in the shaft to hoist to the surface. Nothing can be done in the drifts on the 1500-ft level until this water is drained. The bottoms of both the middle and north winzes are still in ore. The ore breasts are all looking well on the 1400-ft level, and are yielding fully as good if not a little better quality of ore than for some time past. Daily yield, 500 tons.

SIERRA NEVADA.—The main east drift at the 700-ft level, now being run for the purpose of prospecting the ore vein at that point, is making rapid headway, the face still in a mixture of clay, quartz and porphyry.

NORTH SAN FRANCISCO.—This is a new mine, located on the north end of the Comstock lode, a short distance north of the Geiger Grade toll house, and nearly on a north and south line with the Utah, Sierra Nevada and Ophir claims. The location is a fine one, the ledge cropping out at two different points on the surface. A fine three-compartment working shaft has been commenced, which is now down 30 ft, finely timbered throughout.

ROCK ISLAND.—The main west drift at the 450-ft station is in 40 ft in fine working ground. It is expected that this drift will reach the ore vein in a distance of 130 ft from the shaft, as the ledge has a strong eastward inclination toward the shaft. The prospects for finding ore when once the ledge is reached are certainly very favorable.

SENATORS.—During the past week the south-east drift on the 400-ft level on the hanging well of the ledge, proving the ore vein to be 20 ft in width, and the quartz of a fine quality, spots of which give assays of gold and silver.

CROSSLAND POTTER.—Daily yield, 40 tons of ore, from the old upper workings. The average assay value of this ore is about \$30 per ton.

SOUTH CALIFORNIA.—During the week a couple of fine looking feeders of quartz have put in an appearance at the bottom of the shaft, one of which widens rapidly, and may develop into something valuable. Water does not interfere.

UTAH.—Putting in the heavy stone foundations for the new and powerful hoisting and pumping machinery is making steady and rapid progress. The new machinery is arriving by the car-load almost daily.

NIAGARA.—Sinking the new shaft is making rapid progress. The ore vein has every appearance of widening out, and the ore at the bottom of the shaft is of a fine character.

LANSY BAYAN.—The recent damage to the pumping machinery has been fully repaired and the water lowered 60 ft. The air connection between the up-raise from the 180-ft level and the winze from the level above is completed. Sinking the winze below the 180-ft level is making steady headway, the bottom still in ore.

BALTIMORE AND AMERICAN FLAT.—The new pumping and hoisting machinery is all working with the utmost smoothness and perfection; the shaft is being drained of water and work resumed at all points on the 850 and 750-ft levels. Cross-cuts have been started too on both the levels to cut the ledge, and the prospects for good ore developments in these mines are growing more favorable every day.

PHIL. SHERIDAN.—More seams of quartz and black clay are coming in, and the indications are very promising for a good ore development before long. There is evidently a valuable ledge ahead.

NORTH CONSOLIDATED VIRGINIA.—The shaft is down 180 ft, the bottom still in ledge material of a fine, favorable character. Assays, ranging from \$5 to \$13 per ton, are frequently obtained, giving great confidence in the future developments, when a greater depth is reached.

MOORE & MOGAN.—The cross-outs in the surface workings continue to show ore which experts pronounce to be of the same character and texture as that found in the great bonanza itself.

TAOY CONSOLIDATED.—The new steam hoisting machinery is now in full and successful operation, and sinking the shaft deeper is being actively prosecuted.

WELLS-FAROO.—Three shifts of hands, working night and day, are putting the shaft down lively. The drift at the 150-ft level is in 40 ft.

SUTRO TUNNEL.—The cave mentioned in last week's report is about 100 ft west of shaft No. 2. Being loose and sliding in from above, it is found to be a very difficult job to drift through the caved debris. But it is being done, however.

PIONEER CONSOLIDATED.—Shaft down over 100 ft, and the work being pushed lively night and day, with three shifts of hands. Sinking in ledge matter. Steam hoisting works will soon be needed.

DANDANELLIS.—The machinery of the old hoisting works of the mine is being fixed up and made ready for action as fast as possible.

DANEY.—Cross-cutting the ledge on the 400-ft level will be resumed in a very few days.

NEVADA.—The cross-cut of the lower level is now passing into a softer and more favorable character of matter, and shows indications of approaching the main ore vein or chimney.

GLOVE CONSOLIDATED.—The pumping machinery has been put in the most perfect condition, and the extraction of the water from

the 400-ft level was commenced this morning.

JUSTICE.—The developments of the south mine and at the 400-ft level go on as usual with excellent prospects in sight, but no new and important feature to make note of.

JULIA.—Sinking the main shaft is making splendid headway, the new "Burleigh" drills working with the utmost perfection. Much better progress can now be made than at any time in the past, everything in and about the mine being in the most perfect working condition.

ORIGINAL GOLD HILL.—Air pipes have been run through to the extreme end of the north drift, allowing of good ventilation and working to better advantage. The ore body developed in the south drift shows splendidly, and the new ore dump will be completed to-morrow or next day, ready for ore extraction and milling whenever the company shall desire.

SOUTH COMSTOCK.—Shaft down 165 ft to-day. The bottom of the shaft is in ledge matter, quartz and clay predominating.

WHITE PINE DISTRICT.

ELKO MINE.—*White Pine News*, May 1: This has always been considered a good mine, and has encouraged the owners by its yield of good ore, but recent developments places it among the best mines of the district. At a depth of 136 feet they have struck the ledge, which is six feet in width, and yielding carbonate ores which assay way up into the hundreds. It is the intention of the owners to take out a large quantity of ore and ship to Eureka for reduction. This is one of the hundreds of similar mines in White Pine district lying idle for the want of a furnace to work the ores. A few more strikes like this will be sufficient comment on the prejudice that exists against the mines of this district. That this prejudice will be swept away, and that soon, hardly admits of a doubt, for no such fortunes as are here for some one to reap, are going to be passed by for any great length of time.

Montana.

THE BLACK LEADS.—*Correspondence New Northwest*, April 16: The big strike before reported caused a great excitement here, and the days of 1864-5 are being lived over again. Old time prejudices, though grown firm and strong, melted in the crucible of excitement like wax before the flame and left the man so divested a willing victim to—quartz. Men were visible in every direction with stakes in arms looking for croppings to pounce upon, and it is now immaterial whether they are green, black, or blue, for one is as likely to be good as another. But this result of all this re-locating will be very beneficial to this district and to all directly or indirectly interested in the prosperity of the camp, as all the fragmentary property heretofore mostly owned by outside "boiled shirt" non-residents has reverted back to men who will develop for a legitimate claim of 1500 linear feet in a body. A new era is now dawning on Summit valley mining district and its vast resources will be more surely and speedily developed and the way thus prepared for ever timed capital to invest. The Travona shaft is now 28 feet deep and the vein has been steadily widened. About 1½ tons of ore have been sacked daily for shipment. On the Parrott lead the different parties still continue stoping out good ore. Messrs. John Downs & Co. are now down 90 feet and are preparing to erect a whim to dispose of the considerable body of water coming into the mine, which is difficult to hoist by manual labor.

THE PIONEER COMPANY. Pioneer, expect to start up in a few days now. Having had a 600-inch ditch for several years, and last year purchased the 400-inch Keystone ditch, they will have plenty of water this season.

Oregon.

RESOURCES OF EASTERN OREGON.—*Oregonian*, April 20: Our readers have become familiar with the Virtue mine near Baker City, which has been sending out its golden bricks for a long time. The Virtue mill had a small beginning, and can make no pretensions to equality with the great mills of Nevada, owned by San Francisco capitalists; but it has successfully opened one or more valuable mines, and is extending its operations constantly.

Then, there is the Rye valley mines, which have already been demonstrated rich in both gold and silver. There is a mill at Rye valley.

At Conner creek, also, is another splendid mine of gold quartz, the richness of which is already established by milling the rock.

At Ronen gulch near Baker City, the McClelland brothers are working a gold bearing "pocket ledge" in which the "pockets" are numerous and very rich. The specimens shown us from this ledge has \$24 in gold in it, by specific gravity test, and in aggregate weight equivalent to \$32.

Over in Grant county, Mr. Cabell is working a ledge of gold and silver, which in California would be the basis of more "big bonanza" excitement than a little. This rock assays \$592 gold and \$1,987.50 silver to the ton. The machinery with which this truly magnificent mine is worked is a little mill of inferior capacity.

Several other ledges known to be rich in the precious metals and partially opened, are waiting for some one to take hold of them.

And besides the precious metals, rich mines of copper and cinnabar were discovered years ago in Grant county, which would prove sources of immense wealth if they were well opened. There is no reason why Eastern Oregon may not in time become as famous as any other mining region in the world.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening last, Dr. H. W. Harkness in the chair. The time of the meeting was principally occupied with the reading of a carefully prepared paper by Charles W. Brooks on "The Origin of the Chinese Races," the object of the writer being to prove that the first Mongolians came from some part of this continent, probably Peru. This paper was one which showed unusual research and study, and is of great general interest. Mr. Brooks has had an opportunity for following up this question, superior to most people. In his extensive travels with the Japanese Embassy, he had with him some of the ablest Japanese historians, men of profound learning, who had made the history of Eastern nations the study of a lifetime. He availed himself of their knowledge on the ancient languages while he was at the Vatican library and that of the British museum, to obtain translations of the old papyrus and hieroglyphs which had any bearing on the question, and has really developed some interesting facts.

The argument may be succinctly stated as follows: Central Asia has hitherto had the credit of being the cradle of mankind. Scientists say that America is older, geographically, than any part of the earth's surface. Therefore in natural process of evolution, the aboriginal man must have appeared on this hemisphere, in the vicinity of the first rocky elevation. The Chinese people are unlike any other people on the continent of Asia. They are hemmed in by mountains and the great wall along their northern and western frontier. They have had no communication with other Asiatic peoples from time immemorial. According to this tradition, their first progenitors landed on the southern coast of China. In looking for the place where they might naturally have been brought by favoring winds and currents, our attention is turned to Peru. The records of that country show an immense antiquity. Their civilization was extremely ancient, and the remnants of an almond-eyed race resembling the Mongolian are found in the Peruvian mountains and also about the headwaters of the Amazon. An armed vessel or an invader might have gone in sixty days from Peru to the southern coast of China. Chinese records show that 3,588 years before Christ, Fo Ki, a stranger king, introduced the recondite knowledge possessed by the Peruvians to the Chinese. The lower roots of the Peruvian idiom are connected with the 216 radicals of the Chinese language. These writings occur all through Asia, and as far west as the Pyramids.

The suggestions of these facts and the many inferences to be drawn from them were elaborated with much detail. It was shown that while Peru had at one time 11,000,000 of inhabitants, her industries had died out and her population disappeared, China had gone on increasing her population indefinitely, and achieved a high degree of civilization. The paper was listened to with interest and applauded at the close.

It was announced that a class in archaeology was being formed at the Academy, so that all who wish to join can do so. It will be under the charge of Mr. W. N. Lockington.

The President stated that at the next meeting of the Academy Prof. Guerin would read a paper on the "Sewerage System of San Francisco."

The meetings, hereafter, will be held at eight o'clock, P. M., as announced by the Secretary.

General News Items.

AMONG the late ventures in California journalism is the Santa Cruz *Local Item*, published by H. Coffin, late of the *Gilroy Advertiser*. Mr. Coffin seems determined to give his patrons a live paper, and from the initial number, which has come under our notice, he bids fair to succeed.

A MAN named John Reynolds, who, until quite recently, was employed as waiter at the Cosmopolitan Hotel, committed suicide last Saturday at the West End House, by asphyxiating himself with gas.

DISPATCHES from various points in the Pennsylvania coal regions report that the strike is still in force, with disturbances at several places.

ANOTHER letter in the Beecher business. This time it is one from Mrs. Tilton to Judge Neilson. What its contents are is just now roasting the brains of the reporters to ascertain.

It has been ordered that a postoffice be established at Allen's Camp, Kern county, California, Henry Clay Coley, Postmaster.

A TRAIN of twenty-three cars loaded with oysters reached San Francisco from the East Tuesday. They will be transplanted in the bay.

The original aspect of the Civil Rights bill has been declared unconstitutional by a North Carolina judge.

The new Palace Hotel at Napa was formally opened last Friday evening.

A WHALE was seen in San Diego bay the other day.

The Pope is ill again.

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Thirteenth Lecture delivered before the University of California College of Agriculture, on Friday, February 5th, by PROF. C. E. BESSEY.

Our Timber Trees.

To the student, as well as to the practical man, the timber producing trees of this Pacific slope furnish a topic of great interest. A well grown tree is a grand object, interesting to every one, from the dreamer who only asks of it that it throw its shade over him, to the lumberman who asks it to yield him the boards, planks, joists and shingles so snugly packed away within its shaggy bark; doubly interesting to the lover of nature, who studies its forms and dwells upon its beauty as if it were an animate thing, who loves it as a fellow creature, and who mourns as for a friend when some ruthless hand fells it. Wonderful machines trees are, pumping up day after day tons of water, which they allow to steam through the millions of breathing pores in their leaves; sending their roots down into the darkness of the earth among the rocks and roots, and bringing up from thence the materials with which they build tall shafts which out-top all other living things. They are nature's masterpieces. Go and stand beside the gigantic *Sequoias* of the Calaveras or Mariposa groves, the *Araucarias* of Norfolk island, or the monstrous gum trees of Australia, and you are with the largest living things on earth.

What thing of life can claim even half the antiquity of some of the trees now growing? Our largest redwoods were seedlings one thousand years ago. Run back if you can over all the changes our English speaking race has seen during the time these redwoods were growing.

Thirty one centuries ago the Big Trees of California burst their seed coats and began their long reaching toward the skies, began adding cell to cell for the construction of spires which should withstand the storms of more than three thousand years. Thirty-one hundred years ago,

Twelve Centuries Before Christ,

When the names of which old Homer sung were still fresh in the memories of men. Our people, our civilization, and our religion have risen since these giant trees began existence.

But what shall we say for the great dragon tree which until within a few years was standing upon the island of Tenerife? Careful estimates placed its age at considerably more than five thousand years. When Moses wrote his account of the world, this dragon tree had been for more than a thousand years braving the storms which swept down upon it from the ocean; when our *Sequoias* were tiny sprouting plants, it had already seen more than twenty centuries; when Rome was in her glory, this ancient tree had passed the meridian of its life. This one living thing spanned with its life the known world; its youth was in the pre-historic past, its old age extended to our present.

Interesting as these inquiries are, I wish, to-night, to call your attention to another view of the matter. Trees, if usable, represent dollars and cents, but if unfit for use, their commercial value is nothing. Now the uses which give value are many; without attempting to enumerate all, they are such as the following: they may furnish food, medicines, timber, gums, balsams, perfumes, spices, dyes, ornaments, etc. But few trees are so poor as not to furnish one or more of these. With us the great demand is that our trees furnish timber. The question of the lecture then, shall be,

What Trees Furnish us with Timber?

A convenient division of timber trees is into "soft wood" and "hard wood" varieties; and under these names timber men and lumber dealers buy and sell the woods found in the market. To the soft wood division belong all the pines, redwoods, firs, spruces, cedars, arched and other cone-bearing trees, as well as the poplars, cottonwoods, lindens, white-wood and a few others. In the hard wood divisions are found the oaks, beeches, chestnuts, hickories, walnuts, elms, ashes, laurels, cherries, maples, locusts and many others.

Among the soft wooded trees the pines stand as of the greatest importance. There are many species which are abundantly distributed throughout the northern half of the globe, and in every country one or more species seem especially adapted to meet the wants of civilized man.

The Scotch pine, *Pinus sylvestris*, called also the Scotch fir, is a tree found in Europe and Northern Asia. It is a fine tree, growing best in the mountainous districts, where it attains the height of upwards of eighty feet, with a diameter of from four to five feet. Its lumber is known in England under the names of red and yellow deal, and is largely used for many purposes.

The white pine, *Pinus strobus*, called also Weymouth pine, is a native of the Northern

United States. In Maine, Vermont, New Hampshire, New York, Michigan, Wisconsin and Minnesota, vast acres were formerly covered by this pine. It is a tall, slender tree, often in this dense forests attaining a height of two hundred feet, with a diameter of but four to five feet. Its wood is for the Northern States what the Scotch pine is for the countries of Europe. It is white, easily worked, reasonably strong and durable, not given to warping or checking, and besides, it takes paint well, all of which qualities at once commend it to the builder and manufacturer.

Its Uses are Almost Numberless.

Yellow pine, *Pinus australis*, is found growing in the Southern Atlantic States, especially in Georgia and Florida, where it forms extensive forests. This is the pine of the South, replacing the white pine of the North. It is not as large a tree as its Northern relative, attaining an average height of less than one hundred feet. Its wood is yellowish in color, dense, heavy and gummy. When dry it becomes very hard, and is then quite difficult to work. Although used in the South for almost all kinds of work, it is especially fitted for use as flooring, and for this purpose it is largely brought to the Northern markets. It is even used somewhat in California for this purpose; a large cargo was landed a short time ago for the Palace Hotel, in the city.

The sugar pine, *Pinus Lambertiana*, of California, may be said to be the Western representative of the foregoing trees. It is botanically a very near relative of the white pine of the East, which it resembles very closely in everything excepting size, being a giant as compared with its Eastern congener. Place two boards side by side, the one from the white pine, the other from the sugar pine, and it would be a most difficult thing to tell which was which. If California had no other conifers, sugar pine would be used for as many purposes as the white pine, but you are so fortunate as to have three or four others having different qualities, so that the use of sugar pine is somewhat restricted. On account of its lightness, firmness, strength, ease of working, freedom from warping, and readiness to take paint, it is largely used for doors, sashes and blinds.

The redwood tree, *Sequoia sempervirens*, is the great lumber producing tree of California. It is not a pine, but is more nearly a cypress, having canes and leaves much more nearly resembling the latter than the former. It is peculiar to this coast, and even here it appears restricted to certain favorable localities. Dr. Gray considers the redwoods (including the giant trees, which are near relatives), as the remnants, so to speak, of

A Former Gigantic Race of Trees,

Which extended throughout the northern hemisphere, climatic and other changes having destroyed them long ago in all countries but California. Beyond the Sierras here and there we find the fossil remains of gigantic trees; and we can trace them away Eastward, even into Northern Asia. Here alone in favored California has the climate remained stable enough to permit their continuance to the present. But even here there has been some change; for now the redwoods are somewhat restricted to certain districts, while we know from fossil and other remains that they once covered portions of the State where now none are to be found. On the tops of the Coast Range mountains are roots and pieces of stumps of ancient redwood forests. They represent a dying race, which specially favoring conditions have given a little longer lease on life.

The Douglas spruce, *Abies Douglasii*, is a native of the Rocky Mountains, Sierra and California regions. A beautiful tree, it was long ago taken to Europe as an ornamental tree for the parks and gardens. Here it is chiefly interesting on account of its timber, which is much sought after by railroad men. Its durability when in the ground makes it very valuable for ties and posts, for which it is much used. It is also brought into the market as boards and planks under the name of spruce lumber.

Oregon pine and Oregon fir are names applied to a very valuable timber brought to our market from Oregon and Northern California. The name pine is not properly applicable to this tree, as it belongs to the botanical genus, *Abies*, the spruces and firs. The wood is firm, light, very strong, elastic and durable. It is used for many purposes, the most important of which is ship building. Ships have been made of this timber throughout, and upon trial have been found as strong as if made from the oaks and other hard woods.

"Soft Wood Ships."

As they are called on account of the lightness of their materials, sink less into the water under a given weight of cargo, than do those made of the heavier woods.

Masts and spars of this timber after bending under heavy winds for days or weeks, as soon as released from the strain straighten up again as before.

There are many other soft wood trees of this region which are now somewhat used, and which no doubt could be utilized if we knew more as to their strength, durability and other qualities. Among these are several pines, yellow pine, *P. ponderosa*; nut pine, *P. sabiniana*; Monterey pine, *P. insignis*. Several additional ones belong to the genus *Abies*—the spruces and firs might be added to the list—as also the giant arbutus of Oregon, *Thuja*; the western larch, *Larix*; western red cedar, *Juniperus*; California white cedar, *Libocedrus*; and some others. Of other soft wood trees than the cou-

isfers, California has none worth mentioning, and with the exception of the tulip tree, *Liriodendron*, of the Eastern United States, none of them are greatly to be desired. With so many valuable soft woods at her command, California has but little need of more, and yet it cannot be denied that

No Tree on this Coast

Furnishes a timber which can exactly replace the wood of the tulip tree, the whitewood or yellow poplar of the Atlantic States.

Among the hard wood trees the oaks occupy the same relative position as do the pines among the soft wooded ones.

British oak, *Quercus sessiliflora* and *Q. pedunculata*, is known wherever British ships have gone. This tough, heavy, durable wood has always been a favorite with British ship builders, and the superiority of the British navy, no doubt, is largely due to the fact that these oaks have always been easily obtained. So important have they been considered, that long ago great plantations of them were made and carefully guarded. Hundreds of the British vessels now floating were made from the oaks which grew from the acorns which

Careful, Thoughtful Hands Planted,

Perhaps two centuries ago.

The live oak, *Quercus vivens*, of the Southern Atlantic States, is for American shipping what British oak is for England. Unfortunately for us, as a native it grows somewhat south of the points where the most of our ships are built, and so it has never been used as much as it might have been, had it been a native of the whole country. California cannot as yet boast of an oak equal to either of the foregoing, possibly because we hardly yet know anything about the native species.

Our common evergreen oak, *Quercus agrifolia*, so common in and about Oakland, thus far has been considered useless as a timber tree. Possibly by proper preparation it may yet be turned to some use.

Tan-bark oak, *Quercus densiflora*, growing in Central California, is now coming into use for the manufacture of wagon and agricultural implements. Under proper preparation it becomes hard, tough and durable.

Canon oak, *Quercus chrysolepis*, found in the ravines and canons of the mountain ranges, is tough and durable, and is said to be of value in ship building. It has, however, been but little used.

The walnut of Europe, *Juglans regia*, is a tree of considerable value in the countries where it grows. In the United States, westward to the Missouri river, it is replaced by the black walnut, *Juglans nigra*, a tree of a thick, heavy growth, producing a valuable dark colored wood, much used for furniture and inside work in houses. Its near relation, the butternut or white walnut, *J. cinerea*, is a smaller tree, producing a lighter colored wood, valuable for the same purposes as the former.

In California a species nearly allied to the black walnut is found rather sparingly. Its wood is valuable, and is used to some extent as a substitute for the former species. It would be well to

Plant Freely,

Not only of the native species, but also of the European, which makes a rapid growth here, and of the black walnut, which, though not a rapid grower, can be made to do well.

The hickory is one of the finest of the trees of the Northern United States. In its bearing it is not very unlike the pines; its straight stem is surmounted by a more or less conical top, often at a very great height from the ground. Its wood is white, hard, heavy and tough, and when properly protected quite durable. As it is subject to the attacks of certain

Wood Eating Insects,

It is not much used in large or heavy pieces, its greatest value being found when employed in sticks or pieces but little more than an inch in diameter. For axles and spokes of wagons and carriages, for handles for tools, and for the smaller parts of agricultural implements it is valuable. California has no native hickory, hence it is found to be quite difficult to grow it here. Possibly in the foot hills it might be grown. It is an experiment worth trying, to make a plantation of hickories in some of the eastern counties, for the State has no wood whatever which can exactly replace it.

The elms are found in great abundance throughout most of the States east of the great plains. Some of the species are quite valuable, though the liability to warp is a serious objection. Europe has a fine elm, the Eastern States have two valuable ones, but California has none. Some of the elms are found to grow quite well in some localities in this State, and no doubt could be grown in sufficient quantities to meet all the demands for elm lumber.

The Ash.

Here again we find, first a species in Europe, which is replaced in the Eastern States by the American white ash, a tall, majestic tree, producing a white, light, tough and durable timber. On account of these desirable qualities it is largely used in the manufacture of agricultural implements. For very many purposes it is preferable to hickory; as it is not so heavy while it is very nearly as strong, and possesses, besides, the additional advantage that it is made free from the work of the powdering insects. In Western California and in Oregon a small sized ash occurs in sufficient abundance to be used in manufacturing somewhat.

The Maples, of which there are many species, are divided into two groups—the hard maples, and the soft maples, referring to the character of the wood. The hard maple, or as it is also

known as the sugar maple, of the Eastern States, occurs as far west as the Missouri river. In favorable localities it becomes a large tree, one hundred feet in height, with a diameter of from two to three or more feet. When dry its wood is hard, and capable of receiving a high polish. The soft maples, of which there are several Eastern species, have a much softer and less durable wood. It is, when kept dry, valuable for furniture, and is largely used for that purpose. In Northern California and Oregon a maple occurs which may be considered as the western representative of the soft maple of the East. It is used considerably.

There are three timber trees peculiar to California which are well worth mentioning; they are the

California Laurel, the Madrona and the Manzanita.

The California laurel (*Oreodaphne Californica*) is peculiar to this slope of the continent. Its wood is valuable, and no doubt when we have learned more fully how to use it, it will be of more value still. The Madrona furnishes a hard, heavy, light colored wood, which is, or can be made to be quite valuable. The Manzanita grows usually as a shrub from which it is difficult to get large pieces of timber. Occasionally, however, it is of sufficient size so that good blocks several feet long and from four to six inches thick may be secured. This wood is very beautiful, much resembling mahogany, but being much heavier and harder. It can be made into many small articles of use and ornament and no doubt by proper care and culture it might be grown into a much larger tree.

Among the important woods of this coast not belonging to California, are those recently brought into use from Mexico. The most important one is what is known as *Prima vera* or white mahogany, a white wood resembling in many of its characters the hickory of the East. It is used extensively in the manufacture of fine furniture, and also for street cars, as well as for many other purposes. Summing up the whole matter we find that California is better supplied with coniferous soft woods than perhaps any other country on the globe, having no less than twelve which are more or less valuable. It has, however, but few soft woods aside from the conifers which are of any value. It is decidedly wanting in valuable hard wood trees.

In order that the native woods of this coast may be of greatest use there is great need of

Thorough and Exhaustive Tests,

As to their strength, their durability and their working qualities. There is no doubt in my mind but that when they are known we shall find that many of the trees which we now pass by as valueless are in reality very useful. I am glad to be able to announce that such tests as those of which I have spoken will be made this year at the university. Only a few days ago the arrangements were completed for beginning the work. In this work I trust you are all interested, and I further trust that you will give it a hearty support as a worthy work of a great and growing university.

I have thus thrown hastily together a few of the facts connected with this subject in order to call your attention to the sources of our timber supply—the kinds of woods we have, those we lack, and the need of a further development, so to speak, of our own woods.

Trusting that the matter presented has not been altogether devoid of interest, that it may receive further thought from you, that you may help to develop this portion of California's resources, thereby adding to its wealth and its material prosperity, thanking you for your attention and patience, I bid you good night.

COAL IN NEVADA.—Learned experts declared that there was no coal in Nevada, but they are now shown to be wrong, for coal is found at various points in the State, and in due time good producing mines of it will be developed, and made available as the cheap fuel of the future. It is found at Crystal Peak, near the western border of the State, also away out in the eastern section. Nearer home, we have the Virginia and the Black Diamond companies actively developing their mines the other side of Carson river, in El Dorado canon and a little beyond. Both produce a very respectable article of coal, which burns well and is made practical use of both in stoves and in the production of steam. We noticed a few days since, in Virginia, a huge lump of the coal from the Virginia coal company's mine, in El Dorado canon. It was brought in a few days ago as a specimen by a gentleman who picked it from the dump while passing, and put it in his buggy. This coal is of the laminated brown lignite variety, strongly bituminous, and burning to clean white ashes. There appears to be plenty of it and each underlying stratum shows improvement. Where it can be cheaply transported by means of a railroad, and furnished in quantity, that coal will be found to be a valuable commodity in the way of cheap fuel. Thus, however, the opinions of experts are set at naught, and coal is found to exist in Nevada as well as California.—Gold Hill News.

In the Julia mine on the Comstock, Burleigh drills of the latest improved pattern are being placed in the shaft, and a six inch air pipe connected with the new powerful compressor with which to drive them. Everything will be in readiness to give these drills a trial to-morrow. It is confidently expected that the progress of sinking will be doubled when the drills are once in good running order.

USEFUL INFORMATION.

Recipes for the Shop.

PAINT FOR BURIED WOOD.—The simplest, and perhaps best, paint to prevent buried wood from decaying is made of boiled linseed oil, into which charcoal is stirred until the whole is of proper consistence. Apply with an ordinary paint brush.

COPPER ALLOY THAT WILL ADHERE TO GLASS.—The following alloy of copper will attach itself firmly to surfaces of metal, glass or porcelain: 20 to 30 parts finely blended copper (made by reduction of oxide of copper with hydrogen or precipitation from solution of its sulphate with zinc) are made into a paste with oil of vitriol. To this add 70 parts mercury and triturate well; then wash out the acid with boiling water and allow the compound to cool. In ten or twelve hours it becomes sufficiently hard to receive a brilliant polish and to scratch the surface of tin or gold. When heated it becomes plastic, but does not contract on cooling.

POLISHING COPPER OR BRASS.—Owing to the irregularities of surface, it often happens that considerable difficulty is encountered in putting a polish on articles of brass or copper. If, however, they be immersed in a bath composed of aqua fortis 1 part, spirits of salt 6 parts, and water 2 parts, for a few minutes if small, or 20 or 30 if large, they will become covered with a kind of black mud, which, on removal by rinsing, displays a beautiful lustrous under surface. Should the luster be deemed insufficient, the immersion may be repeated, care always being taken to rinse thoroughly. All articles cleaned in this way should be dried in a hot dry sawdust.

Filing.

This seems an easy matter to the uninitiated. A simple thing to run a file over a piece of metal. This is far from being the case; for a skillful workman will, in a given time, cut away a far greater quantity of metal with a file than one who is unskillful, for he makes every tooth cut into the work, instead of rubbing over it. To do this, he must adapt the pressure and velocity of motion of the file to the coarseness of the teeth, and the hardness, brittleness, and toughness of the material he is working upon.

To file flat requires much practice; that is, to avoid rounding the edges of a narrow piece of work. Many apprentices find this a most difficult thing to do; in fact there are some who never succeed in filing, smoothing, and polishing without rounding the edges of their work.

The power of filing squarely and well is one of the merits of a good watchmaker.

In filing flat surfaces, it is quite an advantage to use a cork to rest the work upon when the form of it will admit of so doing—place the cork in the vise—use the file with one hand, the pressure on the file being communicated by the forefinger. It is mainly to aid the workman in filing flat that the rounded or bellied form is given to files.

The Art of Drawing.

The art of drawing, by which we imitate everything that is beautiful, and transfer to paper or canvas the creations of our imagination, is not only pleasing as an accomplishment, but is also of practical utility in every branch of study. All cannot expect to attain to equal excellence; there is no one who does not possess some little taste, which, with proper cultivation, will develop itself in some degree of artistic beauty. As in music, so in drawing, to become a master of the art requires long labor and constant application; and still it is within the reach of all to acquire such a knowledge, and such an experience, as to produce pleasing effects and cultivate our tastes for the beautiful in art and nature. If we put our mind and hand to the work we may feel sure of the most gratifying results; and each successive difficulty overcome, and every new idea gained, will add knowledge, experience and encouragement.

The proper materials for drawing are either black lead pencils, or black lead fixed in a port-crayon, charcoal, red, black or white chalk, pastels or crayons, pens or hair pencils, and Indian ink. Black is as proper in the beginning to practice after the plainer lines, etc., as any other material, and the stroke it makes, being smooth, will please the young beginner better than what is effected by crayons.

PERFORMANCE OF SMALL ENGINES.—A correspondent of the *Scientific American* has been trying to arrive at a practical test of the value of the nominal horse power of small steam engines. He communicates the result as follows: "Some time ago I tried an experiment with a two horse power engine, in order to ascertain how it compared with the power of a horse. The latter, working in a treadmill attached to a 22 inch circular saw, was two hours in sawing a cord of pine wood, making four cuts and five sticks. The engine attached to the same saw performed the same amount of work in just forty-five minutes; the cylinder was 3½ inches in diameter by 6 inches stroke. Steam pressure was 35 to 40 lbs., and the revolutions of the engine about 300 a minute. The power was transmitted through a 4 inch belt running from a 19 inch balance wheel on the engine, directly to the pulley on the saw. The horse could stand the work only part of the day at a time; but the engine was good for every hour in the day and every day in the week.

Shrinking of Seasoned Timber.

The shrinking of timber works a greater detriment to the wheelwright than to the work of any other artisan, hence no one should be more thoroughly informed with regard to the character of the timber he is called upon to manipulate than the wheelwright. A late number of the *American Builder* contains some hints in this direction, which we give below:

The various kinds of oak, and some other kinds of valuable timber, will shrink more or less every time the surface is dressed off even a small fraction of an inch. Wheelwrights, accustomed to work in oak, are well aware of this fact, and a correct appreciation of it often enables them to turn out work of a superior character, even of ordinary materials, by first blocking out the piece roughly, then allowing the timber to season, and afterwards working the various parts by degrees, as the seasoning process becomes more and more complete. White oak spoke timber, for example, may be allowed to remain in rough state half a score of years, under shelter, without becoming seasoned so thoroughly that the timber will not shrink after the spokes have been dressed out.

Carriage wheels have often been made of the choicest of oak timber after every spoke had been seasoned for several years, and to the great surprise of the wheelwright, every spoke would work in the joints before the vehicle had run three months. The defect in such instances could not be attributed to inferior timber nor to perfunctory workmanship; but simply to this one circumstance—that the parts of the wheels were put together before the timber had ceased to shrink.

To prove that the best quality of oak will shrink after a spoke has been dressed out, let a tenon be made on one end and driven immediately into a mortise; after a few days' exposure in a warm workshop the spoke may be easily withdrawn. The same fact will hold good in the manufacture of woodwork of any kind where oak is employed for tenons. In order to make joints that will never start, the piece on which the tenons are to be made should be dressed over several times, until the shrinking has ceased. Then let the tenons be made. After these have shrunk, while exposed to the drying influence of a warm workshop, the spokes, or other parts, may be driven into their respective places, with the assurance (especially if they are dipped in oil paint previous to driving,) that the timber will shrink no more.

Many kinds of farming implements, in the manufacture of which oak and ash are used, render very unsatisfactory service, simply because the seasoned timber was not allowed to shrink before the tenons were driven into the mortises. In like manner, oak chairs, and other oak furniture, will frequently shrink to such an extent that the pomels, rungs, dowel-pins and banisters will all work loose, if the precaution was have described is not observed.

Rotary Engines.

The rotary engine is a favorite subject of experiment with inventors, which they do not suffer to lapse into obscurity for want of perseverance. At the fair of the American Institute, last fall, there were four or five of these machines, varying in design and detail, but uniform in the theory upon which steam was applied. The simplicity of the rotary engine is an argument advanced in its favor by persons who imagine that it will one day come into general use; yet some of the most complicated engines we have seen are upon this principle. There has long been more than a suspicion in the minds of manufacturers that there must be a good reason for the want of confidence shown toward this form of steam engine, and engineers know that, for a given amount of power, a rotary engine requires a much larger boiler than a reciprocating engine. A careful and systematic trial was made last fall at the fair of all the rotary engines present, and sets at rest the question of economy. The results show that to produce one horse power per hour the best rotary engine required twelve pounds of coal; while the commonest reciprocating engine, with a properly constructed side valve, does not take more than four to six pounds of coal per horse power per hour. Instances are on record where a horse power has been produced with less than two pounds. One test at the fair showed that one engine present took forty-five pounds of coal per horse power per hour.

Despite the unfavorable showing, as above, it should by no means be considered decisive against all possible rotary engine devices. The problem of a practical rotary engine may be a difficult one to solve, but it should not yet be considered an impossible one. The advantages of a direct over a reciprocal motion in the steam engine are enough to serve as a powerful stimulus to invention in this direction. A large recompense is sure to come to the inventor of a thoroughly practical rotary steam engine.

A TUNNEL UNDER THE STRAITS OF GIBRALTAR. A company has recently been formed in Spain, the object of which is to unite Europe and Africa by a tunnel under the Straits of Gibraltar, between Tarifa and Algeiras on the Spanish coast to Ceuta and Tangier on the Morocco shore. The submarine portion will be nine miles in length. The enterprise offers more difficulties than the similar work under the English channel, although the latter will have more than twice the length as the maximum depth of the channel at the point to be traversed is but 163 feet, while that of the straits is 2,621 feet.

GOOD HEALTH.

Using the Same Towel.

Health follows neatness and disease the departure from it. The use of the same towel by many, common in a public place, though more allowable than the use of the same tooth brush, is nevertheless a not much healthier practice. A prominent oculist says that the contagious Egyptian or granular inflammation of the eyes is spreading rapidly throughout this country, and adds, "I have in many, and I may say in the majority of cases been able to trace this disease to the use of the so-called rolling towels. Such towels are generally found in our country hotels and the sleeping apartments of the working classes, and being thus used by nearly every one, are made carriers of one of the most dangerous, and as regards its symptoms, most troublesome diseases of the eye. I therefore would strongly recommend that the use of the rolling towel be abolished, for thereby we will discard one of the great instruments for the spread of such a dangerous disease of the eye, by which thousands of workmen are annually deprived of their means of support."

APoplexy—WHAT PRODUCES IT.—A middle-aged physician once said to the writer: "As I was walking down the street after dinner I felt a shock in the back of my neck, as if some one had struck me; I have not felt well since. I fear I shall die, just as all my ancestors have, of paralysis. What shall I do?" The answer was: "Diminish the tension on the blood vessels, and there need be no fear of tearing them in weak places." Now this expresses in plain terms the exact cause of apoplexy in the majority of instances; and it is one, too, which every one has it in his power to prevent.

A blood vessel of the brain, from causes which will presently be mentioned, has lost some of its elastic strength; food is abundant; digestion is good; blood is made in abundance, but little is worked off by exercise; the tension on every artery and vein is at a maximum rate; the even circuitous flow is temporarily impeded at some point, throwing a dangerous pressure on another; the vessel which has lost its elastic strength gives way, blood is poured out, a clot is formed, which, by its pressure on the brain, produces complete unconsciousness. This is the apoplectic stroke. It will be perceived that there are two leading conditions upon which the production of the stroke depends: a lessened strength in the vessel, and an increased tension on it.—*Popular Science Monthly*.

SIMPLE DYSPPEPSIA REMEDIES.—Dyspepsia arises from a great variety of causes, and different persons are relieved by different remedies, according to the nature of the disease, the constitution of the patient and condition of the stomach. We know of a lady who has derived great benefit from drinking a tumbler of sweet milk—the richer and freer the better—whenver a burning sensation is experienced in the stomach. An elderly gentleman of our acquaintance, who was afflicted for many years with great distress after eating, effected a cure by mixing a tablespoonful of wheat bran in half a tumbler of water, and drinking it half an hour after meals. It is necessary to stir quickly and drink immediately, or the bran will adhere to the glass and become pasty. Coffee and tobacco are often very detrimental to persons troubled with dyspepsia. As a general thing they should be avoided by persons afflicted with dyspepsia; although they may not be especially injurious to some constitutions, when used moderately. Regular eating of nourishing plain food, and the use of some simple remedies like the above, will effect in most cases quicker cures than medicines obtained from the druggist.

MIND AND HEALTH.—The mental condition has far more influence upon the bodily health than is generally supposed. It is no doubt true that ailments of the body cause depressing and morbid conditions of the mind; but it is no less true that sorrowful and disagreeable emotions produce disease in persons who, uninfluenced by them, would be in sound health; or if disease is not produced, the functions are disordered. Not even physicians always consider the importance of this fact. Agreeable emotions set in motion nervous currents, which stimulate blood, brain, and every part of the system into healthful activity; while grief, disappointment of feeling, and brooding over present sorrows or past mistakes, depress all the vital forces. To be physically well one must, in general, be happy. The reverse is not always true; one may be happy and cheerful, and yet be a constant sufferer in body.—*Brooklyn Journal of Education*.

REMEDY FOR NEURALGIA.—A friend of ours who suffered severe pains from neuralgia, hearing of a noted physician in Germany who invariably cured the disease, crossed the ocean and visited Germany for treatment. He was permanently cured after a short sojourn, and the doctor freely gave him the simple remedy used, which was nothing but a poultice and tea made from our common field thistle. The leaves are macerated and used on the part affected as a poultice, while a small quantity of the leaves are boiled down to the proportion of a quart to a pint and a small wine glass of the decoction drunk before each meal. Our friend says he has never known it to fail of relief, while in almost every case it has effected a cure.

DOMESTIC ECONOMY.

Is Alcohol Food?

This is one of the questions of the present day to which the voice of scientific men returns various answers. The prevailing idea seems to be that it is food in a very small degree. The latest authoritative announcements on this subject have been made in a very interesting series of lectures by Dr. Richardson. He comes to the conclusion that alcohol cannot by any ingenuity of excuse for it be classified among the foods of man. It neither supplies matter for construction nor heat. On the contrary, it injures construction and reduces temperature. This conclusion is the result of a long series of experiments, extending over three years, on warm-blooded animals of various kinds, including birds; on the human subject in health and on the same subject under alcoholic disease.

Foods, as supplied to the human system, are of two kinds, tissue-building foods and heat-applying foods. Nitrogenous bodies perform labor of the first kind, tissue-building, and probably are, to a small extent, heat-producers too. Alcohol, however, contains no nitrogen and cannot therefore rank as a tissue-building food. This conclusion will surprise many who have noticed how ale fattens people, but this fattening is the result not of the alcohol but of the sugar or starchy matter which is taken along with it, and it would appear that drinkers of pure spirit, i. e., spirit unmixed with sugar do not fatten upon it.

There is no doubt but that alcohol is used up in the body, that it is assimilated in some manner. Careful and long continued experiments have been made by many scientific men on this subject. The late Dr. Anstie, especially, made some exhaustive experiments in the matter, and came to the conclusion that of the alcohol administered but a very small fraction was yielded by all the secretions combined. He proved that an animal, a terrier dog, weighing 10 lbs., could take with comparative impunity nearly 2,000 grains of absolute alcohol in ten days, and that on the last day of his regimen, he only eliminated by all the channels of elimination 1.13 grains of alcohol. This fact was of itself sufficiently remarkable, but another still more important remains to be told. In completion of his research after an animal had been treated with alcohol, as above described, Anstie killed it, instantly and painlessly, two hours after it had received the last quantity—95 grains—of spirit. Then the whole body, including every fragment of tissue with all the fluid and solid contents, was subjected to analysis, with the result of discovering only 23.66 grains of spirit.

Alcohol, it thus appears, is decomposed in the animal body. By its decomposition in air, heat and power may be obtained, and why may it not then in the other case? The answer to this, that it is not. As a result of his researches Dr. Richardson recognizes four progressive stages of change of animal function from alcohol, which are shortly described as follows:

The first is a stage of excitement when there exists that relaxation and injection of the blood vessels of the minute circulation with which we have become conversant. The second is the stage of excitement with some muscular inability and deficient automatic control. The third is a stage of rambling, incoherent, emotional excitement, with loss of voluntary muscular power, and ending in helpless unconsciousness. The fourth and final stage is that in which the heart itself begins to fail, and in which death in extreme instances of intoxication closes the scene. These stages are developed in all the warm-blooded animals, and the changes of temperature throughout the whole are relatively the same.

In the first stage the external temperature of the body is raised. In birds—pigeons—the rise may amount to a fall degree on Fahrenheit's scale; in mammals it rarely exceeds half a degree. In man it may rise to half a degree, and in the confirmed inebriate I have seen it run up to a degree and a half. The heat felt in this stage might be considered as due to the combustion of the alcohol; it is not so, it is in truth a process of cooling.

In the second stage, the temperature first comes down to its natural standard, and then declines below what is natural. In birds it reaches from one and a half to two degrees; in other animals, dogs and guinea pigs, it rarely exceeds one degree; in man it is confined to three-fourths of a degree.

During the third degree the fall of temperature rapidly increases, and as the fourth stage is approached it reaches a decline that becomes actually dangerous. In birds the reduction may be five degrees and a half, and in other animals three. In man it is often from two and a half to three degrees. There is always during this stage a profound sleep or coma, and while this lasts the temperature continues reduced.

Thus it would appear that alcohol fails also as a heat-producing food; that it is, in fact, a lowering of the temperature. These facts are of great interest to those living in cold climates where spirits are so frequently taken to "keep one warm." It is well known that men exposed to long continued cold cannot venture to use spirits.—*Ex.*

in Nevada, 302.

Charles Burleigh and His Drill.

The inventor of the celebrated Burleigh drill
arrived in San Francisco last week, on his first
visit here since 1845, at which time, judging
from his present appearance, he must have
been a very youthful voyager.

We last saw Mr. B. in the Patnam machine
works (of which he was part proprietor), in
Fitchburg, Mass., in 1867. He was then the
owner of more than a dozen patents on his
pneumatic drill, which seemed at that date to
be a complete device. He has added many im-
provements since, and doubtless a number of
patents, in simplifying its operation.

Our prediction in 1867, accompanying the
first newspaper illustration of the device, has
been slowly but positively verified, viz.: that
it would prove to be a great desideratum for
large mining and other tunneling operations
on this coast. And now it is safe to say that
fairly started on its errand here, it will, in con-
junction with cheaper and more powerful
blasting agencies, create much of its own field
for future operations. It will render feasible
and profitable many large mining enterprises
formerly impossible to carry through without the
aid of such improved machinery.

If properly supported in his enterprise, Mr.
Burleigh proposes to build up a special man-
ufacture of his drills and air compressors in San
Francisco. In this he has struck a key note which
must certainly resound to his credit. It will
tend to the perfection of his inventions, to the
benefit of our manufacturing interests, and to
the profits of the manufacturers. He should
not be allowed to waste time in finding cap-
ital or proper encouragement to start such an
enterprise in what is already becoming the lead-
ing mining mart of the world.

Nearly all of the best mining inventions of the
past twenty years have been made on this coast.
Mr. Burleigh's drill was born on the wrong
side of the mountain. It would have grown
into use twice as fast on this side, where it
naturally belongs—with its inventor.

Coal and Asphaltum.

A Few Hints to Prospectors.

Within the past year the attention of many
of our prospectors has been turned to coal and
quicksilver, instead of silver and gold. At
present prices of quicksilver, mines of that
character, unless very good, are of little value
to the common miner. Indications of coal, or
what is supposed to be coal, have been found
in many places in this State, and at present
considerable prospecting is being done for it.
Some brief items of information concerning the
distinctive qualities of coal may therefore be of
interest to some of our readers. The best
classification of coals, satisfying both the re-
quirements of science and commerce, is that
which does not take into consideration the
geological age, but only the quality of the com-
bustible. By means of such an arrangement
coals may be divided into two classes. First,
non-bituminous, comprising anthracite or stone
coal; and second, bituminous, common or pit
coal, included under four heads, 1st, caking
coal; 2d, splint or hard coal; 3d, cherry or soft
coal; and 4th, cannel or perrot coal.

From anthracite the passage is into graphite
and even diamond, which is pure crystallized
carbon, while cannel coal passes into brown
coal, imperfectly earthy lignite, into fossil
wood with its fibrous tissue preserved and
finally into peat and turf, so that the complete
series would be diamond, graphite (which is
nearly pure carbon), anthracite, common coal,
lignite, fossil wood, peat and turf. There is
some dispute at present among geologists as to
the nature of the California coals, whether true
coals or lignite, but the public, who do not
understand such discussions, only want to
know in new discoveries whether there is really
any coal, and whether it burns well.

The most important kinds of coal or fossil
carbon are the anthracite, the black or stone
coal proper, and the brown coals (lignite);
the latter two may also be termed bituminous
coal, both furnishing tar when distilled. As-
phaltum resembles bituminous coal consider-
ably, but contains much more oily matter.
As there is considerable of this material in Cal-
ifornia, and it is not so easy to distinguish it
from coal as may be imagined, we give their
distinctive chemical properties briefly as
follows:

Anthracite cannot be kindled by the flame of a
candle. When heated in a retort or flask it
yields, with the exception of a little water, very
little or no embitimate of bitumen (tar), and
which placed before the blow-pipe it is slowly
consumed, leaving a small residuum of ashes.
Boiled in a solution of potassa, it gives no
color to the liquid.

The bituminous or brown coal, as well as the
asphaltum, inflame by the light of a candle and
burn with elimination of a bituminous odor.
When heated in a flask they yield brown and
brownish yellow tar drops.

Asphaltum and bituminous stone coal impart
to potassa, when boiled therein, only a very
slight yellowish color or none at all. If their
powder is boiled in ether (which is best done
in a flask or on a tube closed on one side and
this placed in boiling water), the asphaltum
colors the ether some, a brownish red. Bit-
uminous stone coal colors the ether slightly yellow.
Asphaltum, however, melts much earlier than
most of the lighter coals, and flows like seal-
ing wax.

Brown coal is distinguished from the former
by giving a brown color to the liquid when
boiled in a solution of potassa. These tests
are simple, cheap and easily applied, and
should be remembered by prospectors for coal
in this country.

Heavy Hoisting Machinery for the Comstock Mines.

The mining machinery now being made and
shipped to the Comstock mines is probably the
heaviest ever made anywhere. The machinery
is of a kind which will not need replacing for
years. Many of the mines are preparing to
sink from 2,000 to 4,000 feet and even deeper,
so that very heavy machinery is required. All
this machinery is being very solidly anchored
in place, and foundations are in many places
laid in solid granite, in beds prepared by ex-
cavating to the bed rock.

As an instance of this class of work, we may
mention the new hoisting works being built in
this city, at the Pacific Iron works, which we
examined this week. This machinery is to go
on the "C & C" shaft—the joint shaft of the
California and Consolidated Virginia mines, on
the Comstock. These hoisting works are being
made on the same principle of those at the Mt.
Diablo coal mines, also manufactured at the
Pacific Iron works, in which the hoisting is
done from the engine shaft, there being no
spur wheels. This will be the first one of the
kind on the Comstock and is of a capacity to
hoist 4,000 feet. There are two engines 26 inch
bore and six feet stroke, fitted with balance
poppet valves and cross-cut off. The cylinders
are very ponderous, weighing 16,000 pounds
each. The weight of the pillow blocks is about
12,000 pounds each, and the bed plates will
weigh between 16,000 and 17,000 pounds each.
There will be one engine on each end of the
shaft, the distance between them being twenty-
four feet from center to center. The main

shaft is sixteen inches in diameter in the main
journals and eighteen inches where the reels
are to be placed. Double reels for flat wire
rope are to be used. The reels commence at
six feet and wind up to fourteen feet in
diameter.

The engines are fitted up with two steam
brakes, one for each reel, and also an independ-
ent hand brake for each reel. The steam
brake is so arranged that the brakeman or
engineer can put it on at will, and if the cege
should rise higher than it ought to a connection
is automatically made so that steam is shut off
from the main engines, and the steam brake
applies itself, barring any possibility of an
accident.

There are six tubular boilers to go with the
machinery, fifty-four inches in diameter and
sixteen feet long. Each pair of boilers is set
independently, the intention being to use only
four at a time, and keep the others for emer-
gencies or for relief boilers. Globe valves are
used to disconnect any pair at any time. The
clutches to throw the engines into gear weigh
4,500 pounds each and have wrought iron
bends shrunk around them for additional
strength. There are no gear wheels at all, and
the two fly wheels act as brake wheels.

The overhead sheave wheels are eleven feet
in diameter. The specifications called for these
twelve feet, but they could not be taken over
the railroad, so the size was reduced. There
are two of them weighing 6,000 pounds each.
These are the largest hoisting works ever sent
to the Comstock, and are well worth seeing.
The machinery will all be fitted up at the
shop before being shipped. Everything is
being handsomely fitted, and the whole will be
a model of strength. The excavations for the
reception of this new and powerful machinery
at the mine are about completed and the
anchor bolts and plates are being placed in
position ready to commence the heavy mason
work.

It is stated that a duplicate of this machinery
has been contracted for by the Lady Washing-
ton mining company, on the Comstock, and
grading is going on at the surface of the shaft
of that mine for its reception.

An Improved Arrastra.

David Trumbull, Jr., of Conlterville, Mari-
posa county, has patented through the MINING
AND SCIENTIFIC PRESS Patent Agency, a ma-
chine of interest to the mining community, for
crushing and grinding quartz, which is, essen-
tially, an improved arrastra, or stone pan. It
consists first in a peculiar construction and ar-
rangement of the grinding surface; secondly,
in a novel construction of the driving shaft that
drives the miller. A pan or tub, similar to the
ordinary grinding pan, which may be made of
wood or metal, is used. On the bottom and sides
of this pan is placed a layer of stones, so as to
provide a surface as possible, and make, in
effect, a stone pan. The miller and standard
are arranged in the usual way. The miller
consists of a skeleton frame in which stones of
various sizes are firmly bolted, so as to provide
a solid stone grinding surface. This makes a
solid stone miller, which can be operated the
same as the ordinary iron miller. The verti-
cal driving shaft steps at its lower end in the
upper end of the standard. A collar fits
around the lower end of the shaft, resting upon
the top of the standard, and is held in place
by chains, which connect it with the upper end
of the standard. The lower half of the driving
shaft is provided with screw threads and a key
seat cut on one side. A nut, which has an
arm depending from opposite sides, moves on
this threaded portion of the shaft, and can be
fixed at any point desired by means of a key
which fits in the key seat. The arms of the
nut extend downward a short distance, and are
then bent outward so that their extremities will
strike two of the opposite standards, where the
nut has been fixed near the lower end of the
crew or driving shaft, and thus drive the mul-
ler when the shaft is rotated. The ob-
ject of thus constructing the shaft and driving
mechanism is to permit the miller to be re-
moved. The inventor of this machine is of
course aware that loose stones have been used
to form a grinding miller in combination with
a lower stone grinding surface, and he claims
only the pan with its stone bottom and sides
in combination with a skeleton miller having
stones bolted firmly thereto, and also the pecu-
liar arrangement of the upright driving shaft.

Society of Engineers.

The regular monthly meeting of the Society
of Engineers of California was held on Tues-
day evening last. President Allard in the
chair. Mr. Dickie acted as secretary. Mr.
Irving M. Scott read a brief paper "On Heavy
Grade Locomotives," which gave details of ex-
periments made at the railroads at the Black
Diamond coal mines. The paper elicited some
little discussion in which several of the mem-
bers took part. The promised discussion on Mr.
Hanscom's paper, read at the previous meet-
ing, "On Screw Propellers," was postponed
on account of the absence of Mr. Hanscom.
The next meeting of the Society will be held on
the first Monday in June, when we believe Mr.
Hyde will give details of experiments with road
engines and some account of the progress of
steam plowing in California. Mr. Hyde has
had great experience in this direction, and as
he has kept an accurate record of his work for
several years, the paper will be a valuable and
instructive one.

Work at the Foundries.

The city foundries are all very busy just now,
as they have been for some time. The prin-
cipal work being done is mining machinery and
house fronts. Mining machinery, especially, is
plentiful and all of our foundries are busy with
it. Few people have any idea how much of
this class of work is being done, unless they
take a walk around among the foundries and
see for themselves. At the

Pacific Iron Works,

The principle work being done is on the heavy
hoisting works for the C & C shaft, described
in detail in another column of this issue. They
are also making an engine 14x30, for the Snr-
rise mining company at Panamint. They are
making for the same company, to go with this
order, a complete 10-stamp mill, pans, settlers,
and all complete. This is all being fitted up at
the shop with timbers and everything, and will
be shipped all ready to set up and go to work.
These works are also making a 10x20 engine to
go to Cerro Gordo district, Inyo county, to be
used at a smelting works there. They are also
making two quicksilver furnaces, one for the
Great Western and the other for the Edith
quicksilver mine. These are of the pattern
known as the "Green Furnace." A 16-horse
power engine and boilers is being made for
each of these furnaces. At the

Occidental Foundry,

Steiger & Kerr, proprietors, they are building
a Janin furnace for Oceanic quicksilver mine,
San Luis Obispo county. This furnace is the
invention of Mr. Louis Janin, M. E., of this
city, and will have a capacity of from 20 to 24
tons per day. In this furnace there will be
about nine feet of ore above the fire bridge,
and as the sectional area of the shaft is about
24 square feet, each foot of height should give
about one ton of ore of 2,000 pounds; though
the weight will vary with the compactness of
the mass and the specific quality of the ore.
If the furnace charge weighs nine tons, then
every hour one ton of ore is drawn out and
the charge in the furnace is lowered by one
foot, then a fresh charge is added. Therefore,
every ton of ore remains nine hours above the
fire bridge and an additional time of three or
four hours below the fire bridge. This, as a
rule, will give ample time for burning the ore
thoroughly. This furnace is not yet completed,
and will be, we believe, the first one of its kind
in this State. At this foundry they are also
engaged in making the well known Hepburn
pans.

The Pneumatic Thermometer.

Mr. Theodore Gidley, of this city, has re-
cently invented a pneumatic thermometer which
is intended for use on board vessels. The ma-
chine consists of a copper cylinder capped by
a diaphragm of stout India rubber hermetically
sealed, the whole being covered with a metal
dome having an opening in its summit to admit
an iron pipe connecting with the deck. A
slight metal rod rests on the diaphragm and
passes up through the pipe to a stand on deck
on which is placed a dial plate. The action of
heat in the cargo is instantly communicated to
the cylinder, expanding the air in it, thus rais-
ing the diaphragm and with it the rod connect-
ing with the hand on the dial, marking the
amount of heat generating, as would an ordi-
nary Fahrenheit thermometer.

Mr. Gidley's invention has received the
unanimous endorsement of the Board of Marine
Surveyors, and considering the number of vessels
which have been lost lately from spontaneous
combustion it certainly appears to have been
invented at a most opportune period. A para-
graph in the London Standard states that her
majesty Queen Victoria has appointed a royal
commission composed of prominent scientific
men of the United Kingdom to examine into
the cause of spontaneous combustion of coal on
board vessels, "and the remedies which it may
be possible to adopt for preventing and guard-
ing against the same." Mr. Gidley's invention
seems to meet the case exactly. The working
model of the machine which we examined may
be seen at Viester & Co.'s, 17 New Montgomery
street, under the Grand Hotel. The intention
is to place three or four of these machines in
different parts of the cargo of a coal ship so that
if the cargo commences to heat means may be
immediately taken to extinguish it. By having
several, the location of the fire can easily be de-
termined. As the machines are simple and
cheap they can be very generally applied to all
vessels.

HOOSAC TUNNEL.—Massachusetts is complet-
ing her big hole by dressing it into shape,
arching places where water drips from over-
head, and preparing for the double track
through its entire length. The central shaft,
which was 15x27 feet in dimension and 1,050
feet deep, has to be closed up on account of
the tremendous draft it created from both
ends of the tunnel. In the winter season the
draft had a tendency to freeze the dripping
water so as to block up the passage of train.
The high range of mountains pierced by the
tunnel runs north and south. In the morning,
the warming up of the atmosphere on the
Eastern slope creates sufficient vacuum to
draw a strong current of air from the western
side of the mountain. In the afternoon, when
the sun strikes hotly on the western side,
the current is reversed.

Short Lectures on Patents.

No. 2.—By JNO. L. BOONE, of Dewey & Co's MINING AND SCIENTIFIC PRESS Patent Agency.

The Model.

A large number of the inventions for which patents are applied for, could be fully and sufficiently represented by proper drawings and specifications without models, and in many cases it seems preposterous to compel inventors to go to the expense of furnishing models, when their inventions could be just as well understood without them. On the other hand, there are some cases in which models are absolutely requisite to enable the examiners to act intelligently upon the applications. With an eye to remedy this difficulty, the new patent law of 1870 left the question as to whether a model should be furnished in any particular case entirely with the Commissioner of Patents, intending thereby to relieve those inventors whose inventions were simple and easily understood; but before the inventor could know what the decision of the Commissioner would be, he was required to present his case without a model, and await the Commissioner's decision. The cure was worse than the disease. In the first place, if the Commissioner should decide that a model must be provided, a long delay was created before the case could be acted upon, and as the models of simple inventions are inexpensive and easily made, this class of inventors preferred to make and forward them at once rather than suffer the delay. In the second place, those whose inventions were complicated and whose models would necessarily be expensive and troublesome to make, were the most eager and persistent in their efforts to have their models dispensed with, and as this class of cases could not be acted upon intelligently without models, the Commissioner had no other course than to use the discretion which the law gave him to compel every applicant to furnish a model whether the invention was simple or complex, and this is now the case. None are allowed to escape this requirement if their inventions can be represented by a model. The object of requiring a model in each case is two-fold; first it assists the examiner in understanding the construction and operation of the device sought to be patented, so that he may act intelligently upon it; and secondly it is a tangible evidence which corresponds with the specifications and drawings of the patent, and serves as an index by which the actual intention of the patentee is interpreted as long as his patent is in force, and to more fully illustrate the invention so that it can be better understood by the public after the patent expires.

In constructing a model much is left to the discretion of the inventor. He can make it of wood, iron, leather, lead or any other durable material, so long as he makes it substantial and shows the devices or particular parts he wishes to cover by a patent. If he chooses he can make it plain and unostentatious, or he can construct and finish it in the highest style of mechanism and art. A frail model is always objectionable and will even be refused by the Patent Office. Where the invention consists of a machine which embodies entirely new ideas or principles or is intended to produce a new result, a complete model showing its construction and arrangement must be furnished; but where the invention is an improvement on some already existing and well known machine, only the invented or improved portion combined with sufficient of the old machine or device to show its relation and arrangement need be represented by the model. In the latter case the old machine can be represented by a dummy or imitation; for instance, if the invention is an improvement upon an ordinary steam boiler, a simple block of wood turned out and painted to represent the boiler can be used, and the improvement can be applied to it, and in this way much trouble and expense can be avoided, while the model is in every respect as sufficient as if the real parts were shown. Model makers generally understand and take advantage of this fact. It is a point greatly in the favor of an applicant to furnish a neat model. It not only creates a better impression upon the examiner who passes upon the case, but also indicates that the inventor has a pride in his invention, and understands how to combine and arrange the parts with a view to practical operations.

As the drawing which accompanies each application for a patent must be an exact representation of the model, and as the drawing accompanies and forms a part of the patent when it is issued, it is of great advantage to the inventor to have the model as complete as possible, so that persons who are not entirely familiar with the machine can more readily understand the drawing when the patent is exhibited to the public.

Again, the model is placed on file in the Patent Office, where it remains as a permanent and tangible representation of the invention. It forms a part of our National Museum, and in fact, is placed on exhibition where it can be examined by all who have the curiosity to inspect it. I will venture that hundreds of in-

ventors have felt ashamed of the models which they have placed on file in the Patent Office to represent their inventions, when they came to examine them where they are placed on exhibition beside other models of more pretensions workmanship. Still I do not advise expensive models. Neatness can almost always be obtained without additional expense.

Many an otherwise good model is spoiled by a thick coat of red, green or blue paint artistically daubed over it, and often the working parts of a model are so completely gummed and glued with varnish that it is impossible to move them. Such jobs are inexcusable.

Hard wood is the best and usually the cheapest material to use in making models, and when finished a simple coat of shellac varnish is all the covering they require. Heavy varnishes should be avoided. If a portion of the model is to represent metal, that portion can be painted black to distinguish it from the remainder. Paint should always be sparingly used, as it gives a model a coarse look. The name of the inventor and title of the invention must be permanently marked upon the model. The cheapest and best method is to paint them on, or engrave them upon a metal plate and attach the plate to the model. Writing the name and title on the wood with ink or scratching them on with a knife makes a good model look common and poor, while the extra expense of having it done neatly and correctly is but a trifle when compared with the difference in appearance.

Brass models always look well when they are first made and polished, but they soon lose

their polish and become tarnished unless great care be taken of them, so that a brass model which is brilliant and showy when it is first filed in the office soon becomes green with verdigris and unattractive. If they are plated with silver or nickel or are varnished, they will always look well.

For the construction and preparation of models for the Patent Office the following rules and requirements should be observed:

Every model must be inside of one foot in each dimension.

The invented portion must be represented in complete order, whether the old parts of the machine are represented by real or dummy mechanism.

Never use glue alone in putting together wooden models. Nails must also be used.

If models are not put together with strength and substantially made they will be rejected.

Never use paint on a wooden model unless it is to indicate a part which is to represent metal.

Never use heavy body varnishes.

Use shellac varnish.

Paint or engrave the name and address of the inventor, and of the invention, on the model.

COPPER is ruling in Liverpool at £79 10s to £80 for good ordinary brands. Ore is selling at 15s 9d to 16s 3d per unit. The arrivals during March amounted to 4,004 tons fine and the quantity of copper float from Chili is now much reduced. There is very little speculation in the copper market, the transactions being mainly done by local and Swansea smelters.

THE NEW incline at the old works of the Caldonia mine is now down 180 feet below the 1000-foot level. It is timbered throughout in the most substantial manner, and the Gold Hill News thinks it is one of the truest and finest pieces of work of the kind on the Comstock lode.

An Improved Fruit Jar.

As the season for canning and putting up fruit approaches, those who intend to put up their winter's supply begin to look around for the best jar for this purpose. We herewith illustrate an improvement in fruit jars which was recently patented by Pierre Darbce, of this city, through the MINING AND SCIENTIFIC PRESS Patent Agency. This improvement relates more especially to the manner of constructing the cover and sealing the jar. The jar *A*, it will be noticed, is provided with a gutter, *C*, around its upper rim, of which the inside wall, *h*, is the highest. The jar may be made of glass, earthenware or other suitable material. The cover, *B*, is made of glass and has a central portion, *E*, which extends downward into the mouth of the jar when the cover is in place. It also has an annular downward projecting rim, *b*, around it, which fits into the gutter, *C*, around the top of the jar. The projection *E*, can be made round or square as desired; around it Mr. Darbce secures a cork, *D*, which will fit down inside of the mouth of the jar; when this cover is forced down upon the jar the cork will fit in the mouth of the bottle inside of the wall, *h*, the annular rim *b* will enter the gutter, *C*. In the bottom of the gutter, *C*, Mr. Darbce places, a piece of wire so that it will pass entirely around the top of the jar; he then fills the gutter with wax so as to seal the joint. He

DARBCE'S IMPROVED FRUIT JAR.

thus provides two joints, an inside cork joint, that prevents the wax from entering the jar, and an outside sealed joint which hermetically seals the jar. He thus prevents the disagreeable consequences of getting sealing wax in the fruit and provides an easy and cleanly method of unsealing and opening the jar, as by taking hold of the end of the wire which lies in the bottom of the gutter and pulling upon it the wax will be lifted out without trouble.

CERRO GORDO DISTRICT.—We see by the Inyo Independent that about the 8th of April, Beaudry's furnace, at Cerro Gordo district, shut down, it was generally supposed, for the usual repairs. It remains shut down and is likely to be for an indefinite term. The reason is the big chimney of ore in the Union is exhausted, and the mine has yielded no ore for two months past. Pending the law-suit it is not deemed advisable to spend money in hunting for more ore, so every man in the mine has been discharged and all work is suspended. Belshaw has ore enough on his dump to keep his furnace running about four months longer. The outlook for Cerro Gordo is not pleasant just for the time being. The Union has been the main stay of this portion of the county, but should it yield no more there are plenty of other mines on that hill quite as promising as it ever was at the same stage of development. Besides that, the Potosi tunnel goes ahead, and is bound to make big strikes.

AT THE Savage mine, on the Comstock, all work on the lower levels is stopped for the present, pending the tearing down of the old gallow of the hoisting frame and the putting in of a new frame adapted to the use of new incline hoisting machinery. This work will occupy from seven to ten days' time, during which interval nothing can be done in the mine. The new incline hoisting machinery is all ready for use as soon as the new gallow frame is completed.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Foreign and American Patent Agency, the following are worthy of mention:

STATIONARY CUTTING AND PLANING TOOL.—Charles Cummings, Virginia City, Nevada. This invention is an improvement in the construction of such stationary tools for cutting and planing metal as are used on lathes, planes, shapers, slotting machines and other like machines. This tool, which is fixed to the ordinary tool holder, consists of a circular metal plate, the rim of which can be made into any desired shape, according to the style of groove or cut it is desired to make. Across the rim of this circular plate is cut a notch or recess, so that one edge of this notch or recess will form a cutting bit. This tool has a hole through its center and a conical boss or hub upon one side, through which the central hole passes while the opposite side of the plate is countersunk around the hole. When the cutting bit of this tool becomes dull it will only be necessary to grind it off until a sharp edge is again presented, and as the tool is circular in form its center rim can be thus utilized and always present a bit of the same size and shape, thus saving greatly in the time and labor involved in grinding ordinary cutting bits. As the rim is filed off in sharpening the bit, the tool is turned in its bearing or socket so as to keep the bit at the proper working point. This tool will be especially useful for cutting screw threads on metal rods, as the rim of the plate or tool can be made wide enough to have a number of threads cut around it, when by filing out a transverse section a number of bits will be provided equal to the number of threads formed around the plate; and by slightly beveling the edge of the plate before cutting the grooves in it, the threads will be graduated in height so that cutting bits or teeth of different heights will be provided. By this arrangement, one tooth will follow in the track of another and cut out a thin shaving, so as to gradually deepen the grooves and thus complete the screw at one operation. Any desired form of bit can thus be provided so as to cut mouldings or grooves of particular shapes. This tool can be used for cutting inside screw threads where the opening is large enough to admit it.

COMBINED SCOURING BRUSH AND WRINGER.—Richard C. May, Sacramento, California. This invention relates to an improved mop head and brush holder, and an improved wringer for the mop cloth, which may be used in connection with the brush. The head consists of a socket, into which the end of the handle is received, and an angular cross bar, into the angle of which one edge of the back of the brush is secured. A spring arm extends out from the socket and is bent so that its extremity will bear against the opposite edge of the brush. The mop cloth is secured to the T shaped end in a peculiar manner. When the mop cloth is to be wrung the handle is pushed and turned so as to twist the cloth between an arm and head of the mop, permitting it to be completely wrung out by the ordinary twisting method. The movable arm on the handle can be moved up or down so as to accommodate the wringer, and when the cloth is used for mopping the arm is moved down close to the head so as to allow the cloth to double over the brush. When the brush is being used this arm is drawn up the handle until the cloth is stretched between it and the head and a pin or other fastening to secure it in place.

IMPROVED WATER ELEVATOR.—This is an improvement in that class of water elevators in which an endless chain or series of buckets are employed for raising the water, and it consists in an improved manner of constructing the buckets and the pulleys over which they pass, so that the chain will be properly supported upon the pulleys and prevented from slipping on account of the weight of water on one side. The chain consists of a number of buckets, each of which is secured to a curved shield or plate, so that the shield forms the front side of the bucket, while its upper end extends back of the opposite side of the upper end of the bucket. The curved plate or shield is wide enough to extend out on each side and form a bearing as the bucket passes the pulleys. The pulleys each consist of two disks, the inner edges of which are turned down a little smaller than the outer edges, so that as the buckets pass between the disks their wings or projecting sides will bear upon the reduced edge. The chain is formed by connecting the extremities of the shields together by rings or links. As the curve of the plates corresponds with the circumference of the pulleys, each bucket will be firmly seated on the upper pulley while it is being emptied.

SADDLE-TREE.—P. B. Horton, San Francisco, Cal. This invention consists in making saddle-trees out of wood pulp, formed in proper shape by compression in moulds. The side bars and cantels of this tree are made of wood pulp, while the pommel is made of metal and secured to the forward end of the side pieces by means of bolts, rivets or screws; or, if desired, the entire tree can be made of wood pulp. This saddle-tree can be made cheaply, and the inventor says it will be strong and light. It is covered with rawhide or other suitable covering in the ordinary way.

Tenth Industrial Exhibition of the Mechanics' Institute, S. F., 1875.

PRELIMINARY ANNOUNCEMENT.

The Board of Managers of the Tenth Industrial Exhibition have the pleasure of announcing that an Industrial Exhibition will be held, under the auspices of the Mechanics' Institute, in the city of San Francisco, to be opened on Tuesday, the 17th of August, 1875, at 11 A. M., and to continue open at least one month thereafter.

In making this public announcement, the Managers desire that those who intend to exhibit should send in their applications for space as early as possible, so as to avoid the necessity of excluding, as has been the case heretofore, the many desirable exhibitors who are unusually tardy in making applications.

The forthcoming Industrial Exhibition will be the tenth held under the auspices of the Mechanics' Institute, and the Managers are justified in saying that it will undoubtedly surpass in completeness of detail and general arrangement any heretofore held.

The last Exhibition was attended by 700,000 visitors, attracted hither by the fame of these Industrial Fairs, and for the purpose of investigation, business and pleasure.

All the available exhibiting space was applied for several weeks before the day of opening, and the Managers were compelled to deny admission to many desirable exhibitors.

The Board of Managers desire particularly that the arts, the industries and natural products of the country should be well represented at the forthcoming exhibition, and no pains will be spared to make these classes of exhibits a special feature there.

The Exhibition will be held in the building constructed for that purpose in 1874, but it will be materially enlarged and improved in many details for the Exhibition of 1875.

The space under roof will exceed 180,000 square feet, or about four and a half acres, exclusive of the Horticultural Garden, which will occupy 24,500 square feet additional.

The location of the Exhibition Building, on Eighth street, between Market and Mission streets, cannot be surpassed for convenience and accessibility, and can be approached from every part of the city by means of the various lines of street railroads, any of which bring visitors within two blocks of the entrance gate.

The utmost care has been exercised in providing for ample ventilation and light, and during the evening the building is brilliantly illuminated by over 5,000 gas lights.

The promenade avenues are broad, and 3,000 seats are provided for the comfort of visitors, for whose convenience there is also an excellent restaurant, under the management of a first-class restaurateur.

Every afternoon and evening the best orchestra the city can supply will disengage excellent music under the direction of an accomplished leader.

The building is always well attended by visitors, and during the last Exhibition over 29,000 were daily admitted for a number of days, and under no similar circumstances can the manufacturer, the mechanic, the inventor, producer or business man so advantageously place himself before the people of the Pacific Coast.

Persons desiring to obtain information, or to make application for space, should address "Managers of Tenth Industrial Exhibition, San Francisco, California," or make personal application as below.

It is expected that the various transportation companies will convey goods intended in good faith for exhibition, at half the usual rates.

Exhibitors from abroad, if they have no agent or consignee in San Francisco, can consign goods and mark the same to the "Manager of the Tenth Industrial Exhibition, 17 Post street, San Francisco," and they will be stored, if they arrive before the day of opening, free of expense; but no charges or expenses for freight or forwarding, etc., will be paid by the Managers.

In order to secure space, application should be made on or before July 20th, 1875.

Blankets will be furnished on application.

Premiums will be awarded as follows, viz: 16 gold medals, 50 silver medals, Society Diplomes, Certificates of Merit and Special Premiums, as the Board may determine.

Blankets for space can be obtained at the Mechanics' Institute on application by letter or otherwise; and any information will be given, by applying to any member of the Board of Managers, as below:

A. S. HALLIDIE.....113 Plus street.
JAMES O. PATRICK.....122 Battery street.
HENRY L. DAVIS.....421 California street.
D. E. HAYES.....213 Fremont street.
ASA R. WELLS.....Mechanics' Mill.
J. B. CONWAY.....Cor. Spear & Harrison streets.
CHAR. ELLIOT.....516 California street.
GEORGE SPALDING.....414 Clay street.
RICHARD SAVAGE.....139 Fremont street.
W. P. STOUT.....604 Merchant street.
J. H. MACDONALD.....217 8th street.
J. P. CURTIS.....320 Jackson street.
R. B. WOODWARD.....Woodward's Gardens.
JAMES SPIERS.....311 Howard street.

To the Librarian of the Mechanics' Institute, or to J. H. CULVER, Secretary, 27 Post street, San Francisco.

Rules and Regulations of the Tenth Industrial Exhibition, Mechanics' Institute, S. F., 1875.

1. The Pavilion will be open for the reception of goods on Monday, August 2d. The exhibition will be open to the public on Tuesday, August 17th, at 11 o'clock A. M.

2. Applications for space must be made on or before July 20th, stating character of exhibit, amount and kind of space required—well, table or floor. And, if cases, state length, width and height of cases. Blankets will be furnished for this purpose, and a class will be in attendance at the Library of the Mechanics' Institute, every day from 12 to 1, and 7 to 10 P. M.

3. All persons presenting articles for exhibition must have them registered by the Receiving Clerk, who will give a receipt for the same, which receipt must be presented when the articles are withdrawn, at the close of the Exhibition.

4. Judges will be appointed by the Board of Managers immediately upon the opening of the Exhibition, to examine all articles presented, in accordance with Article III, and the Managers will award premiums on such articles as the judges shall declare are worthy, which will be delivered as soon as they can be prepared. Due notice will be given of the announcement of premiums.

5. The mornings of each day, until 10 o'clock, will be appropriated to the Judges, and no visitors will be admitted during the time thus appropriated, except at the special request of the Judges, or by permission of the Managers.

6. Articles intended for sale may be labeled accordingly, but cannot be removed until the close of the Exhibition, except by written permission of the Managers.

7. Steam power will be provided, so that machinery of all kinds may be seen in actual operation, and every facility possible will be given to exhibit working machinery to the best advantage.

8. The name of every article must be attached by the exhibitor to it.

9. Articles intended for exhibition must be entered and placed on exhibition on or before Saturday, August 21st.

10. Perishable articles will be received, or may be removed at any time during the exhibition, with the consent of the Managers.

11. The most effectual means will be taken, through the agency of the Police and otherwise, to guard and protect the property on exhibition; and it will be the purpose of the managers that all articles shall be returned to the owners without loss or injury. Still, all articles deposited will be at the risk of the OWNERS.

12. In case of any misunderstanding, application may be made to the Managers, who will at all times be in attendance.

13. The Managers are desirous that articles should be presented early. Those from abroad, intended for exhibition, should be properly packed, and if not consigned to exhibitor's agent, must be marked, "MANAGERS OF TENTH INDUSTRIAL EXHIBITION, SAN FRANCISCO, CAL." All articles thus received, arriving too early, will be stored free of cost to the exhibitor, and the Managers will have them duly placed in proper position for exhibition. No freight charges will be paid by the Managers; but exhibitors are notified that arrangements are being made with various transportation companies to repay freight charges on evidence of goods exhibited.

Information will be furnished by addressing MANAGERS OF TENTH INDUSTRIAL EXHIBITION, SAN FRANCISCO, CAL.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labor of canvassing, by lending their influence to encouraging favors. We intend to send none but worthy men.

Mining and Other Companies.

Benjamin Mill and Mining Company—Location of principal place of business, San Francisco, California. Location of works, Devil's Gate District, Lyon County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 14th day of April, 1875, an assessment of \$2.00 per share was levied upon the capital stock of the corporation, payable on the 21st day of April, 1875, in United States gold coin, to the Secretary, at the office of the company, Room 7, 401 California street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 21st day of May, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 14th day of June, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

LEANDER LEAVITT, Secretary.
Office, Room 7, 401 California street, San Francisco, Cal.

California Consolidated Mill and Mining Company. Location of principal place of business, San Francisco, Cal.

Notice.—There are delinquent upon the following described stock, on account of assessment levied on the 1st day of April, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Burke, T.....	33	100	\$ 50 00
Burke, T.....	34	50	25 00
Burke, T.....	35	50	25 00
Hendy, Joshua.....	34	70	35 00
Hendy, Joshua, Trustee.....	73	24,550	12,275 00
Hendy, Joshua, Trustee.....	78	2,116	1,058 00
Beard, John.....	39	50	25 00

And in accordance with law, and an order of the Board of Directors, made on the 1st day of April, 1875, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of the company, 408 California street, room 16, on the 18th day of May, 1875, at the hour of 1 o'clock P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

Office, Room 16, No. 408 California street, San Francisco, Cal.

Carbon Coal Company—Principal place of business, San Francisco, California. Location of works, Contra Costa County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 1st day of May, 1875, an assessment of \$1.25 per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, N. O. Fassett, No. 220 Clay street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 1st day of June, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the 14th day of June, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

Office, No. 220 Clay street, San Francisco, California.

Cincinnati Gold and Silver Mining Company—Location of principal place of business, San Francisco, California.

Notice.—There are delinquent upon the following described stock, on account of assessment levied on the 17th day of March, 1875, the several amounts set opposite the names of the respective shareholders as follows:

- The Abbott Mine, Lake County.
- The Buckeye Mine, Colusa County.
- The Cerro Bonito Mine, Fresno County.

KNOX & OSBORN.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Suprs. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness of first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 60 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

This is a Sure Cure for Screw Worm, Scab and Foot Rot in Sheep. It also kills Ticks, Lice, and all Parasites that infest Sheep.

Prevents scratching and greatly improves the quality of the wool. One gallon of the Dip properly diluted with water will be sufficient to dip one hundred sheep, so that the cost of dipping is a mere trifle, and sheep owners will find that they are amply repaid by the improved health of their flocks.

This Dip is guaranteed to cure when used according to directions, and to be vastly superior to Corrosive Sublimate, Sulphur, Tobacco, and other remedies which have heretofore been used by farmers.

Circulars sent, post paid, upon application, giving full directions for its use, also certificates of prominent sheep growers who have used large quantities of the Dip, and pronounce it the most effective and reliable known Cure and Preventive of Scab and other kindred diseases in Sheep. mrls-bp

VOLUME XXX
Number 20.

An Improved Dry Ore Concentrator.

John Vincent, Sr., of this city, has recently patented, through the agency connected with this office, an improved machine for concentrating and separating the heavy particles of dry pulverized ore from the light and worthless portion. The machine consists of a number of peculiarly constructed plates or concentrator trays, placed one above the other in a closed box. The box is mounted on journals inside a frame, and the frame is provided with appliances for handling the box and giving it the concentrating sleeve motion and concussion.

The accompanying engraving is a perspective view of the machine from one corner. A is a strong box which is mounted on journals, b, between the two sides, C C, of a frame. The journals, b, bear in hangers, D, which are suspended from the middle of each side of the frame, so that the box can swing in the frame, and be tilted so as to bring either end uppermost. Inside the box are placed the concentrating trays, e e e, one above the other, one inch apart. Each tray consists of a plate of metal, or other suitable material, having parallel rows of depressions or cavities, f, made in it transversely across the plate. These depressions or pockets are separated by a metal strip, g, which is so secured to the plate that one edge will project considerably above the level of the plate, while the opposite edge is fastened closely to it, thus providing an inclined division plate between the rows. The depressions or pockets, f, serve to receive and retain the heavy particles, which are settled by the motion and concussion given to the box, and the projecting edge of the separating plate prevents the particles from moving in one direction, while it does not prevent them from moving in the opposite direction. The ends of the box, A, are closed by doors, H. The hinged end, H, has side boards, which are made in the shape of a quadrant, so that they can move in a narrow slot or space at each side of the box when opening or closing the ends. Both of the upper corners of the sides, C C, of the frame are connected by strong shafts, K. The shaft, K, with the lever, has a fixed arm, l, extending downward near each end, and the lower ends of these arms are attached to the opposite ends of a rod, m, which extends across and is secured to the end of the box by detachable fastenings as shown.

By securing a lever, n, to the middle of this shaft, the box can be swung back and forth motion. A stop bar, p, is secured near the hangers, D, against which the hangers strike when the box moves forward, so as to produce a concussion for settling the heavy particles of ore by gravity. This need not be used if a concussion is not desired.

In operating the machine the rod, m, is detached from the box, A, which is then turned by means of the shaft, K, and rope or chain, Q, used in the manner of a windlass, so that it will stand on one end inside the frame. The hinged end of the door at the upper end of the box is then opened, and the pulverized ore is shoveled into the box until it has been fully charged. The door is then closed, and the box is moved back to its horizontal position by means of the windlass. In this case the hook on the end of the rope, Q, is attached to a ring on the lower end of the box, and the roller turned until the box is in the proper position. The rod, m, is then again secured to the end of the box, and the lever, n, applied to the shaft so as to form a handle for operating the box. This operation causes the heavy particles of ore to settle through the light portions into the depressions in the trays. The direction of the concussion is such that the heavy particles will be prevented from moving over the trays by the projecting edges of the strips, g, so that when they will settle into the cavities they will remain there.

After the agitation has been continued long enough to thoroughly concentrate the ore, the box is tilted one way to discharge the light or waste portions from the lower end of the machine, and by tilting it the other way the valuable contents can be discharged from the other

end. A double concussion can be given to the ore, if desired, by using double stops or knockers for the pendent arms, D, to strike against. For this purpose a pivoted bar, X, similar to a pawl, is secured to the frame opposite the stop bar, p, as shown. This bar can be used or not as desired. A horizontal plate, y, is secured to each of the hangers, D, and extends along the box, A, and through the corner part of the frame. The plate has two or more holes in its end, into which a hook, z, on the corner part, can be placed, so as to hold

Fig 1

Fig 2

BROOKS' CORK-SOLED BOOTS.

the box in a horizontal position when required. Although the machine is especially intended for concentrating dry pulverized ore, it can also be used for concentrating wet ore by submerging the machine after it is charged, in a tank of still water, and giving it the motion described. This would of course greatly favor the concen-

Vincent's Dry Ore Concentrator.

tration, as the water would keep the particles loosened up and allow the heavy particles to settle more readily. It will be seen from this that the machine is adapted to localities where water is scarce, and may be used for working tailings. It can be run either by hand or steam power. The inventor can be addressed care of this journal.

Almost the entire business portion of Eberhardt, White Pine district, Nev., was destroyed by fire on the 12th inst.

Improved Cork-Soled Boots.

The accompanying illustration represents a novel plan for making boots and shoes with cork soles. A very thick but very light sole is provided, which effectually keeps out the cold and wet of winter, and in summer shields the foot from the excessive heat of the sun-baked pavements. The device is as easily repaired as the common sole, and its use in bad or

Air Sollars.

In ventilating mines a natural current of air may often be produced in a long level by means of an "air soller." To form an air soller the floor of the level carrying the tram road is laid about six inches above the actual bottom of the level, and is supported by cross sleepers, resting upon blocks of wood or stones. A simpler method still, when in soft ground, is to cut the center of the level somewhat deeper than the sides. Planks are then laid over the sleepers mentioned to form a kind of deck, the whole being rendered air-tight by plastering with mud. This will divide the tunnel into two very unequal portions. Through the lower division or air soller a current of cool, and therefore heavy air, will pass into the end, and this will be further cooled if there be water issuing from the lode at any points. The air heated by the breathing of the men, burning of candles, etc., will pass on through the level itself, and so a constant current will be kept up. The level should be as truly level, or "dead" as possible, for several reasons, two of which may be here mentioned: First, if there be water flowing out through the level, and the fall be considerable, the rapidity of the current of water will, to some extent, check the incoming current of air. Second, if the level rise rapidly the floor at the upper end will soon be at a higher actual level than the back of the entrance, when the heated air will actually have to descend in order to make its escape, although the natural tendency of heated air is always to ascend.

A level can, of course, be ventilated the same as shafts sometimes are, by having a pipe run to the back end from the mouth. The opening of the pipe at the tunnel mouth is enlarged, and a current of fresh air is forced into the tunnel. This mode of ventilation, however, can only be adopted when there is wind; but it is in time of calm that underground ventilation is most wanted. To meet this difficulty a small fan, worked by hand, water or steam, is arranged to force pure air in, or, still better, to draw the impure air out. In many cases a jet of high pressure steam from a boiler may be discharged into the outer end of the pipe, when an outer current will be at once set up.

Work at the Foundries.

The San Francisco Boiler Works will remove about the first of June from its old location on Beale street to the northwest corner of Harrison and Main streets. Mr. Curry informs us that he is now working 357 men, and working about twenty-three hours out of twenty-four. They have in course of construction a large amount of hydraulic pipe; one lot for the Auburn H. G. M. Co., is about completed. They have just completed eleven miles of iron water pipe, twenty-four and forty-eight inches, for the Contra Costa water company.

At the Miner's foundry and machine shop orders are being filled for Mexico, Chili and Peru, as well as Pacific coast orders. This foundry is now turning out all the work for the Diamond Drill company.

The Hope iron works, over on the Potrero, are not yet in running order. The buildings are, however, all completed, and some of the machinery is in. Considerable of the machinery needed here was ordered from the East, by Mr. Hanscom, and it has not all arrived as yet. Everything in these works will be brand new, and of the best patterns obtainable. We hope before long to see Mr. Hanscom carry out his own ideas on a fast steam launch, both as to model and machinery.

The Grading at the Prospect mine, on the Comstock, for the foundation for the new hoisting works building, and the new and powerful steam hoisting machinery, about being erected, is being driven ahead with all the vigor possible. The main hoisting works building will be 40x120 feet in size, with carpenter and blacksmith shops immediately adjoining on either side of the main building.

PROFESSOR R. E. ROGERS, of the University of Pennsylvania, has left Philadelphia lately for San Francisco, to superintend the construction of an extensive bullion refinery in the new mint. It is expected that the new refinery will be completed and in readiness for operation in about ninety days.

A TOLL ROAD company has been organized to build a toll road from Battle Mountain, Nev., to Silver City, Idaho, by way of Caruncopia and South Mountain. Work has been commenced. The road will be 183 miles long.

The graders are at work on the fourth mile of the Los Angeles and Independence railroad, between Santa Monica and Los Angeles.

STEAM hoisting machinery has been ordered for the new shaft of the Europa mine, on the Comstock.

CORRESPONDENCE.

Geological Formations—Quartzite.

EDITORS PRESS:—With the advancement of geological research, which may now, in spite of its many shortcomings, be classed as a science, mineralogists as well as practical miners are leaning upon its conclusions as an index to their fields of operation. Consequently, the inquiry is almost universal with the latter classes, when a new mining locality is announced—what is its geological formation? In most instances the answer may be readily given by a mere novice in geology. Not so, however, in all. As, in regard to a knotty legal problem, it is often remarked that "it would puzzle a Philadelphia lawyer," on the assumption, probably, that they have reached the *ne plus ultra* of legal acumen; so with the geological problems of some localities, and especially in regard to this mining district, he may well say that it would puzzle the most astute geologist to give a very satisfactory elucidation.

The portion of the district containing the mineral belt is called quartzite. There are a few granite dykes, so called, although from the entire absence of mica in them, except in one instance that I have seen, they are more probably syenite. A few small trap dykes, a few inches in thickness, and an occasional cropping of silicious limestone, or, as some writers call that kind of rock, "calcareous quartz," make up the formation. The silicious limestone also appears in the form of dykes. Now the query arises, what is quartzite? Of course it is composed almost entirely of silica, and Dana defines it to be a granular quartz. But this quartzite is not granular, except in a few places; it has more of a vitreous structure. Some pronounce this to be a metamorphic structure. But metamorphism would not obliterate its seams of stratification and cleavage, and the evidence in other respects is very slight on which to base such a conclusion.

In some localities in California and Nevada there are dikes perfectly identical with our quartzite, from a few inches to twenty feet in thickness, but I have not been able to learn of any general formation of miles in extent made up almost entirely of this species of rock. Again, in all other localities quartzite, so far as my observation or information extends, is non-metalliferous. The reverse is true here in an eminent degree, as I will show quite fully in future communications. Yet, although "argenteous galena ores exist here in such vast stores as to astonish miners from other points, it must be confessed that the mining interests are not prosperous. The reason I alluded to in a former communication, and affords a striking exemplification of what all success men will meet with when they take hold at the wrong end of things, or "put the cart before the horse." Instead of procuring their coke for smelting from a distance of twelve to fifteen hundred miles, at a cost of \$35 per ton, it could and should be procured almost at our own doors, say from a distance not to exceed seventy-five or eighty miles, and an article equally as good. A concert of action to that end by those most interested, or by private individual investment, which would be highly remunerative, would work an astonishing and rapid change in the prosperity of this inter-oceanic region. WILLIAM TEAL.

Bingham, U. T., May 1.

TIMBER FOR THE CENTENNIAL.—In a letter from Whitefield, Oregon, published a few days since, mention was made of a gigantic mast-cut at Puget's sound, by Mr. Brown, a New Englander, who is engaged in the lumbering business in that locality. It was stated that the stick was a foot through at the upper end. The dimensions should have been stated as follows: 120 feet in length and 42 inches through at the top. Trees grow to an enormous size there as in California. A Mr. William Squire of Norenton, Oregon, writes to the Centennial Commissioner for Oregon that he will furnish at Tillamook bay, a fir plank, twelve feet wide and one hundred feet long; a spruce plank eight feet wide; cedar, seven feet; larch, seven feet; Hemlock, five feet. He says he can get much larger ones if transportation could be furnished, and can also supply hard wood planks of like proportion, including shittim wood, of which Noah built his ark.

THE BLACK HILLS scientific expedition, now being organized at Cheyenne, under orders from the Interior Department, for the purpose of establishing the boundaries of Northern Wyoming and ascertaining the mineral resources of the Black Hills, will not be able to start before the end of the present month, owing to the cold weather. The party consists of Professor Walter J. Jenny, geologist in charge, formerly of the Texas Pacific railroad survey; Henry Newton, assistant geologist, of the Ohio survey; Captain H. P. Tuttle, astronomer, of the Cambridge observatory; F. P. Gillicuddy, telegrapher of the Northern boundary; D. Newberry, and a corps of surveyors. The delegation of Indians from the Black Hills country en route to Washington, in charge of Agent Saville, will start about the 10th inst.

On the Assay of Sugar.

[Written for the Press by HENRY G. HANKS.]

The determination of sugar by chemical means is attended with difficulties which render the results more or less inaccurate, according to the skill of the chemist.

Several methods have been proposed—all more or less objectionable—but the one based on the reaction of grape sugar on sulphate of copper is generally preferred.

The weak point of all chemical determinations of sugar is that only the practical manipulation of a skillful chemist ensures their correctness, and the above mentioned method is not an exception.

I have never seen this process explained in such a manner as to be easily understood by the unscientific reader, and this paper is an attempt to supply the deficiency.

The assay is based on the well established fact that one equivalent of grape sugar reduces exactly ten equivalents of oxide of copper to the sub-oxide.

One equivalent of grape sugar has the following composition:

12 Equivalents of Carbon....(C ₁₂) =	72
12 Equivalents of Hydrogen...(H ₁₂) =	12
12 Equivalents of Oxygen.....(O ₁₂) =	96
	180

Let this sum be represented by (A) (A = 180.)

One equivalent of oxide of copper consists of	
1 Equivalent of Copper (Cu).....	31.7
1 Equivalent of Oxygen (O).....	8
	39.7

Let (B) represent 10 equivalents of oxide of copper (B = 397.)

One equivalent of sulphate of copper contains	
Oxide of Copper (CuO).....	39.7
Sulphuric Acid (SO ₃).....	40.0
Water.....(5H ₂ O).....	45
	124.7

[124.7 = (C).]

By the above it is shown that the oxide of copper in one equivalent of sulphate of copper = 39.7 = (D)

Formulas.

It is required to make a solution of anhydrous copper in which the oxide of copper in a litre shall equal five grammes of grape sugar. The amount of sulphate required is found by the two following equations:

1st. The oxide required, found thus:

$$A : B :: 5 : X \quad (X = \frac{B \times 5}{A}) = 11.03.$$

2d. The amount of sulphate of copper containing this amount of the oxide, found thus:

$$D : C :: 11.03 : X \quad (X = \frac{C \times 11.03}{D}) = 34.64$$

Preparation of the Standard Copper Solution.

(E) 34.64 grammes of pure and dry crystallized sulphate of copper, previously pulverized and pressed between folds of blotting paper, is carefully weighed and dissolved in 200 C.C. distilled water.

In another vessel 173 grammes of double tartrate of soda and potash, (Rochelle salt) is dissolved in 480 C.C. of a solution of pure caustic soda of specific gravity = 1.14. The two are then mixed and the deep blue solution diluted to the volume of one litre and filtered. This solution will keep for some time if the precaution is observed to preserve it in full bottles and in a dark place.

When in the proper condition it can be boiled without decomposition. It is therefore necessary, if it has stood for some time, to test its condition by boiling. If a precipitate falls it is worthless. This solution is decomposed by boiling with grape sugar, but is not acted on by cane sugar.

1 Equivalent Cane Sugar =

C ₁₂ =	72
H ₁₂ =	11
O ₁₁ =	88 = 171

It may be here stated that 100 parts of grape sugar equal 95 of cane sugar.

As it has been shown that the sulphate of copper in one litre of this solution is equivalent to 5 grammes of grape sugar, it is evident that each 100 C.C. is equal to .5 grammes of grape sugar, or .475 grammes of cane sugar. (.5 × .95 = .475). Cane sugar can be converted into grape sugar by boiling its solution with dilute acid. As the optical properties of the sugar are changed by this operation the cane sugar is said to be inverted.

To prove the strength and purity of the standard copper solution, dissolve .475 grammes of the whitest and best loaf sugar, perfectly dry and clean, in a little distilled water in a clean porcelain dish. Boil with 30 or 40 drops of dilute sulphuric acid, (1 part strong acid to 5 parts water,) for half an hour, replacing the evaporated water from time to time, keeping the volume the same. This solution, diluted to 100 C.C., should exactly decompose and discharge the color from 100 C.C. of the copper solution. Before diluting the sugar solution, the acid should be carefully neutralized with carbonate of soda.

The sugar to be assayed should be diluted with water, so that it contains not over one per cent. of sugar. If it is of a dark color, the solution must be heated to boiling, a few drops

of milk of lime added, filtered through animal charcoal, washed and diluted to a measured volume.

Example.

(F) Ten grammes of sugar to be assayed is dissolved in 300 C.C. distilled water, hoiled in a clean porcelain dish for half an hour with 10 C.C. of dilute sulphuric acid with precautions given above, the acid neutralized with carbonate of soda, milk of lime added if necessary, the whole thrown on a filter in which some animal charcoal has been placed; when the solution has nearly all run through the filter, it is washed with distilled water until every trace of sugar is removed; the washings now containing all the sugar are made up to the volume of one litre and thoroughly mixed. Each 100 C.C. of this solution contains one gramme of the sugar. 50 C.C. of the copper solution (E) is placed in a clean porcelain dish, 200 C.C. of water added, and the whole brought up to gentle boiling. The dilute sugar solution (F) is then added from a graduated burette, until the precipitated oxide of copper has a vermilion red color; the lamp or burner is then removed and the precipitate allowed to settle. The dish must then be held in a good light near a window, and gently tilted to one side so as to allow the clear liquid to flow over the white porcelain uncovered with the precipitate. If any blue color remains, more sugar solution must be added while boiling. When the color is wholly discharged the operation is ended, and it is only necessary to note the quantity of liquid used as indicated by the graduation on the burette, and to make the calculation.

It should not be expected that the first trial will be correct, but it will be a guide to the second or third, which can be made perfectly so. Suppose the first test required 43 C.C. of sugar solution; in making the second 40 C.C. may be safely run in at once, and the last few C.C. carefully added drop by drop.

The sugar necessary to discharge the color from 50 C.C. of the copper solution contains .25 grammes of grape sugar, (it having been shown that 100 C.C. is equivalent to .5 grammes).

The calculation may be understood by the following example:

42 C.C. of sugar solution (F) discharged the color from 50 C.C. of copper solution (E). 84 C.C. would, of course, do the same for 100 C.C. of copper solution. .84 or 84 C.C. of the sugar solution therefore contains .5 of grape sugar. .01, or 1 C.C. would contain .00595 (.5 ÷ 84 = .00595).

One gramme of the sugar, or 100 C.C., would then evidently contain .595 grammes of grape sugar, and 100 grammes, 59.5, which is 59.5 per cent. This amount multiplied by .95 would equal 56.52 per cent. of cane sugar.

Sometimes sugar contains both cane and grape sugar, mechanically mixed. In this case the grape sugar already present must first be estimated and the amount found be deducted from the total grape sugar, after invertingly acid.

Suppose a case, a solution of sugar is made as described in (F), a portion is boiled with copper solution before treating with acid. Grape sugar is present if any red oxide of copper falls. Two solutions must in such cases be made exactly alike; except that one is boiled with acid and the other is not. We will call these solutions "No. 1, hoiled with acid," "No. 2, not hoiled with acid."

The titration is the same in both cases. As No. 2 will not generally contain as large an amount of grape sugar as No. 1, it will require a greater volume of solution to discharge the color from 50 C.C. of the copper solution.

Example.

No. 2 required 324 C.C. to discharge color from 50 C.C. copper solution; 324 C.C. therefore contains .25 grammes grape sugar; 100 C.C. (containing 1 gramme of sugar), contains 25 ÷ 3.24 = .77 = 7.7 per cent.

Let No. 1 result as in the first example. The result would then stand as follows:

Total Grape Sugar.....	59.5 per cent.
Grape Sugar in No. 2.....	7.7 per cent.
Grape Sugar resulting from	
acid in No. 1.....	51.8 per cent.
51.8 + .95 = Cane Sugar. 49.21 per cent.	
Cane Sugar =	49.21 per cent.
Grape do =	7.70 per cent.

Total Sugar.....56.91 per cent.

*C.C. means Cubic Centimeters, or thousandths of litre, French measure.

CAPE COD SHIP CANAL.—The old project of making a ship canal across Cape Cod is under vigorous discussion at Boston. The Legislature having recently granted an extension of time to the company, in which to complete the work. The company has a nominal capital of \$1,000,000. They want to begin operations within a year, and if they do the contract for constructing the canal will be given to European parties. The entire cost would be nearly \$3,000,000. The valley through which the canal is to pass is north of the town of Sandwich, and extends from shore to shore about 7½ miles, and in a direct line from the waters of Buzzard's Bay to those of Barnstable Bay, about 6½ miles, the general direction of the course being northeast and southwest. The canal is intended for tow boats and barges, but would also be of sufficient capacity for all vessels now engaged in the coasting trade around the Cape. It is claimed that the canal would reduce the distance by the Vineyard Sound route nearly eighty miles, and fully 140 miles by the outside route around "Fishing Rip."

Sierra County Mines.

A correspondent of the *Mountain Messenger* says: After twenty-five years of gravel mining in this vicinity, in ravines, bars and benches that have been as rich as any place in the known gold regions of the world, it is no wonder that the chief reasons that have made this place prosperous should in that length of time be exhausted, and dullness be a general complaint. Miners and business men must look to some other source for a revival of that prosperity that all are so anxious to see realized. After setting aside the gravel claims on the mountains, where untold wealth has never been disturbed, and which requires a large amount of capital to develop, we must look to another and more permanent source to bring back those good old times that the pioneers delight to dwell upon. And there is quartz mining, the source from whence all the alluvial gold has come. The number of ledges that gold is known to exist in, in and around here, have richly fed the gravel claims. The ledges that are now lying idle from various causes have, very few of them, had any thorough systematic work done on them, or labor applied to bring out the hidden, rich deposits they must contain.

The one great drawback has been the old district mining laws that allow a person a hold on a claim for years, and willing prospectors were debarred from trying to develop any ledge that was known to contain gold, the owners, like the dog in the manger, would neither work their claims nor allow others to do so. Again, sometimes the owners have asked impossible prices, where little work has been done, and by that means deterred capitalists from taking hold of them; consequently they are no benefit to any one.

Another drawback has been San Francisco adventurers that have come here with a slight acquaintance with perhaps some men of capital, trying to get the ledge for a mere trifle, and misrepresenting them below, and turning anything into stock, they retaining the greater part, and by false and wild reports they make money for a time, but in the end supplies are stopped, and prospecting is discontinued. My opinion is that when a poor man has discovered a ledge, and the rock is to be crushed by machinery, and he has a chance to sell at a fair price, the best he can do is to let it slide, and use the money to find a better ledge. By this means we induce capital to come in, and the capitalists once successful, you will see men testing quartz on every mountain and hill-side, and in my belief not all in vain. One great want is a custom mill, one that will save the gold, with all the latest appliances. When the miner knew that his rock had a fair test and he could take one ton or fifty and have it crushed, and by that means make a living while he was prospecting, I fully believe that Downville would see again, not the wild, extravagant days, but a prosperity and contentment that would be far more pleasant in a social view, and the rising generation, instead of emigrating, make a home in the place of their birth.

Fireless Locomotives.

A correspondent, writing from New Orleans, Louisiana, says: Fireless locomotives are in constant and successful operation on a city and suburban railway in New Orleans; namely, the New Orleans and Carrollton railway, under the able management of Gen. G. T. Beane, who is a skillful engineer, and yet who is alive to, and keeps pace with, the improvements of the age. This success has been achieved, too, under the most adverse and unpromising circumstances. The road, under other running arrangements, had become nearly valueless, its stock having gone down to seven cents; but it is now a paying and valuable road.

The road is about six miles in length. From the center to the outskirts of the city it is run by mule power; there the mule is taken from the car and the little fireless locomotive is attached, which is accomplished in less time than would be occupied in attaching another mule. The train is then off like a rocket, the driver still on the platform of the car, working the engine, managing the brakes, and making change as usual; there is no other person on the train to attend to these duties. The car is started and stopped quicker than when drawn by the mule.

The locomotive is simply a cylinder of boiler iron, perhaps three feet in diameter and ten feet long, mounted on four wheels and partly filled with water. The engine (a double vertical) is attached to the end of the cylinder next to the car, being within reach of the driver. The cylinder is then filled with steam at a proper pressure, from a stationary boiler at Carrollton, when the locomotive is ready, and it will run to the city and back without care or expense. There is no fire, no ashes, no pump, no danger, and less noise than from the hoofs of horses. The expense of this means of propulsion is less than by mules. The cost of the locomotives is \$1,250 each, which includes the builder's profit.—*Ex.*

A vein of graphite was recently discovered near Greggville, in Gold run district. The mineral is said to contain ninety-seven per cent. carbon, and is probably the finest quality of plumbago found in the United States. The vein is about six feet wide and as well defined as ore quartz leads generally.

About 5,000 workmen belong to the Virginia and Gold Hill miners' union.

MECHANICAL PROGRESS.

Apparatus for the Fusion of Platinum.

We have already made mention of the construction, at the Conservatory of Arts, at Paris, of the international standard apparatus, in which operation the largest mass of platinum was employed which was ever melted at one time. The furnace was constructed on a principle already before used by M. Deville and Debroy, but which, in this instance, greatly exceeded the dimensions of any previously employed for such a purpose. The experiment, as already reported, succeeded beyond expectations, and demonstrated the feasibility of liquification by heat of unusually great masses of platinum—the limit to which is not, of course, as yet been reached. This experiment will, no doubt, have an important bearing in the future progress of art and science.

The ingot of platinum which was taken from the interior of the apparatus had a volume of 1.15 litres, its length being 1.15 metres, its width 0.17 metres, and its thickness 0.08 metres. The value of the mass of metal is estimated at \$50,000. Following is a description of the furnace, as recently given by M. Deville.

The furnace of the conservatory is 1.4 metres in length; it is formed of the stone of Saint-Waast, the substance of which is a fine-grained limestone, containing about five per cent. of silica. When it is necessary to melt a small quantity of platinum in the laboratory, by the aid of the oxy-hydrogen blow-pipe, a crucible of unslaked lime is used, as it is the action of the highest temperature obtainable.

This substance, however, does not admit of construction of a crucible of large size. M. Deville and Tresca have had recourse to limestone and carbonate of lime.

Under the action of heat the surface of the lime is decomposed, the carbonic acid is evolved and leaves the lime with which it was united. With ordinary limestone this escape of gas causes great inconvenience, as the bubbles of gas pass through the bath of molten lime and form irregularities on its surface; besides, the ingot after cooling firmly adheres to the lime with which it is in contact. It is necessary to find a stone of special quality.

That of Saint-Waast, being porous and highly pulverized, gives the very best results. In platinum is melted in the cavity in the stone the carbonic acid only escapes along the borders of the liquid mass without passing through it; the decomposition of the limestone is placed to the depth of about 0.02 metre, so the metal really rests on a bed of lime of a considerable depth.

At two ends of the furnace are two cylindrical openings, through which the bars of platinum to be fused were successively introduced. When the seven blow-pipes, represented on the upper part of the cover, through which they pass, were lighted, the platinum melted with great rapidity. Small openings gave a view of the interior and the melting of the metal. It was of a dazzling silver-white, as bright as mercury, and formed a reflecting surface like that of a mirror. By the lateral openings the large, intensely luminous flames could be seen hurrying forth. The temperature was in the neighborhood of 2300°C., which is a little above the melting point of platinum.

The seven blow-pipes were connected by rubber tubes with reservoirs of illuminating gas and oxygen. These tubes are attached to each other and united by a sphere of copper.

The consumption of oxygen in the experiment of May 13th was nearly 120 litres per gramme of platinum; in the former operation a volume of 150 litres was required. The results recently obtained are in favor of the arrangement of the beautiful apparatus of the Conservatory of Arts and Measures.

MAGNETIZATION OF STEEL.—The magnetic force is limited to a certain thickness, which can never exceed. This limit varies in different steels. It is very great in those which are soft, and diminishes as the proportion of carbon and manganese and as the temper is harder. Certain bars which the author has studied show that he has specimens where it is less than 1-10 m.m. The latter only receive what may be called a superficial magnetic coating, the thickness of which it is not possible to augment by increasing the intensity of the current. If by the depth of the magnetization diminishes along with the magnetic conductivity, the intensity of the magnetism increases. It follows that the quantity of magnetism is subject to two canons of inverse variation—the depth to which increases, and the intensity which lessens, as the conductivity increases.—*M. J. Leclercq.*

AMERICAN LINE OF EUROPEAN STEAMERS.—The Boston Commercial Bulletin reports the construction of a fleet of trans-Atlantic American-built steamers to be ahead of any now afloat in speed and carrying capacity.

Interesting Incident in the History of Nail Manufacture.

The difficulties which the early workers in iron were so often called to encounter is forcibly illustrated in the following incident connected with the history of the old splitting mills so common in early days of rolling mills, given in Scribner's "History of the Iron Trade."—"The most extraordinary and the best attested instance of enthusiasm existing in conjunction with perseverance is related of the founder of the Foley family. This man, who was a fiddler, living near Stourbridge, England, was often witness of the immense labor and loss of time caused by dividing the rod of iron necessary in the process of making nails.

"The discovery of the process called splitting, in works called splitting mills, was first made in Sweden, and the consequences of this advance in art were most disastrous to the manufacturers of iron about Stourbridge. Foley, the fiddler, was shortly missed from his accustomed rounds, and was not again seen for many years. He had mentally resolved to ascertain by what means the process of splitting of bars of iron was accomplished; and, without communicating his intention to a single human being, he proceeded to Hall, and thence, without funds, worked his passage to the Swedish iron port. Arrived in Sweden, he begged and fiddled his way to the iron foundries, where, after a long time, he became a universal favorite with the workmen; and, from the apparent entire absence of intelligence, or anything like ultimate object, he was received into the works, to every part of which he had access. He took the advantage thus offered, and having stored his memory with observations of all the combinations, he disappeared from amongst his kind friends as he had appeared—no one knew whence or whither.

"On his return to England he communicated his voyage and its result to Mr. Knight and another person in the neighborhood, with whom he was associated and by whom the necessary buildings were erected and machinery provided. When at length everything was prepared, it was found that the machinery would not act; at all events it did not accomplish the sole end of its erection—it would not split the bar of iron. Foley disappeared again, and it was concluded that shame and mortification at his failure had driven him away forever. Not so; again, somewhat more speedily, he found his way to the Swedish iron works, where he was received joyfully, and, to make sure of his fiddler, he was lodged in the splitting mill itself. Here was the very end and aim of his life attained beyond his utmost hope. He examined the works, and very soon discovered the cause of his failure; he now made drawings or made tracings; and having aided an ample time to verify his observations, and to impress them clearly and vividly on his mind, he made his way to the port, and once more returned to England. This time he was completely successful, and by the results of his experience enriched himself and greatly benefited his countrymen. This I hold to be the most extraordinary instance of credible devotion in modern times."

AMERICAN BESSEMER IMPROVEMENTS IN ENGLAND.—Four years ago an American engineer who had had considerable experience at the Bessemer steel works of this country, and who was in England at the time, offered the Barrow steel works complete details of the improvements in the working of the Bessemer process in America for a very small royalty per ton. The offer was not accepted, and we presume the managers were not a little astonished at the insolence of the "hardest Yankee" in attempting to teach them. Last September Mr. Holley, another American engineer, read before the Iron and Steel Institute (England) a paper showing that by these despised American improvements we were getting from one-half to three-fourths more work out of a pair of Bessemer converters than the English. And Mr. Smith, the manager at Barrow, stated that "they, at Barrow, would endeavor to see why they could not do as well with regard to quantity as they had done in the United States." And now comes this satisfactory part of the whole affair to the American engineer first mentioned. A few weeks since a gentleman from these same works at Barrow, where his offer was refused, came into the Bessemer works where he is engineer to examine them, doubtless to carry out Mr. Smith's idea of "seeing why they cannot do as well at Barrow." There was a look of quiet satisfaction on the countenance of our friend as he related these circumstances.—*American Manufacturer.*

A NEW BELTING MATERIAL.—In engineering shops in Germany a new kind of belting is being adopted. It is made from hair, presumably that of the alpaca, and is delivered by the makers in a single piece without seam. It has a coating which consists principally of masticum. It is spoken of as most satisfactory, and being more durable than either gutta-percha or leather.

THE SAND-BLAST.—The contractors who have undertaken to furnish 240,000 headstones for the national cemetery at the names, in their works at Rutland, Vt., by means of the sand-blast. This is a name in four minutes, and they complete 500 stones daily.

FLAT AND ROUND BELTS.—A three-fourth inch round belt, running in properly grooved pulleys, will convey the same power as a two inch flat belt.

SCIENTIFIC PROGRESS.

Development of Magnetism in the Rails of Railways.

M. Heyl, engineer of one of the German railways, in a recent report upon the special section under his charge, calls attention to the development of magnetism in the rails. He says: "I have observed that all the rails are transformed at their extremities, after they have been placed in position a few days, into powerful magnets, capable of attracting and of retaining a key or even a heavier piece of metallic iron. These rails preserve their magnetism even after they have been removed, but they lose it gradually. When in position, however, the magnetism is latent, only becoming free when the chairs are removed, and disappearing again when they are replaced. Hence it is necessary to assume that two opposite poles come together at each junction, and that each rail is a magnet, the poles being alternately reversed throughout the line. This production of magnetism in the rails examined is undoubtedly attributable to the running of the trains and to the shocks, frictions, etc., thereby produced. The hypothesis of electric currents, induced or direct, must be rejected, since it is negatived by experiments upon the subject made with suitable apparatus. Although the interest attaching to the fact above stated is at present purely scientific, it is not impossible that the magnetism thus developed may exercise an influence actually beneficial upon the stability of the roadway, increasing the adherence to the rails and the friction. It is possible also that the magnetic currents may be stronger at the moment of the passage of the trains, than either before or after. If this be so, the observations may acquire a still higher practical importance.

Excrementitious Matter as Fuel.

The scientists have not yet done with devising ways and means for utilizing excrementitious matter. The latest reported experiments in this direction have been conducted by Dr. Petri, of Berlin, who has perfected a process for producing odorless blocks of fuel from excrements, which also burn without odor, with a heating effect equal to brown coal, and affording an ash excellent as a phosphate fertilizer. The excrements are first rendered perfectly odorless in the receptacles before removal, by the addition of a chemically prepared powder, and are then concentrated by evaporation in a peculiarly constructed vessel (without the least annoyance to persons present), to the consistency of clay, and the mass then delivered by the machine, so as to be cut by wires into blocks, which are pressed and dried like bricks. It is not necessary to separate solid from liquid excrements, and the disinfected matter can be transported at any time without annoyance to any one. Since the machines act rapidly, and without requiring many hands, the establishments need not be very large or remote. The results of experiments conducted before the authorities of Berlin are said to have been very satisfactory, and calculations were made according to which it would appear to be very economical to the city to remove excrementitious materials in this way.

THE AGES OF DARKNESS.—The ignorance which prevailed during the Middle Ages respecting the geography of the earth is surprising. The true orthodox system for more than ten centuries taught that the earth is a quadrangular plane extending 400 days' journey east and west, and exactly half as much north and south; that it is inclosed by mountains on which the sky rests; that one of these mountains on the north side, higher than the others, by intercepting the rays of the sun produces night; and that the plane of the earth is not set exactly horizontally, but with a little inclination from the north; hence the Euphrates, Tigris and other rivers running southward are rapid; but the Nile, having to run up hill, has necessarily a very slow current. It is important to state, however, that such vagaries were not believed by every one. There were, even in those dark times, a few superior minds that rose above the ignorance, superstition and ecclesiastical dogmatism of the age, and groped their way into a less murky light. But gross ignorance enshrouded the minds of the masses, and a horrible intellectual darkness prevailed, which was deeper than the pall of night. Advancing science has fortunately brought to us a better knowledge of nature.

NEW IMITATION SILVER ORNAMENTS.—In several stores in Munich various objects of art have lately been displayed, which are remarkable for their brilliant silver luster. It appears that they are mere plaster models covered with a thin coat of mica powder, which perfectly replaces the ordinary metallic substances. The mica plates are first cleaned and bleached by fire, boiled in hydrochloric acid, and washed and dried. The material is then finely powdered, sifted and mingled with collodion, which serves as a vehicle for applying the compound with a paint brush. The objects thus prepared can be washed in water, and are not liable to be injured by sulphuretted gases or dust. The collodion adheres perfectly to glass, porcelain, wood, metal, or papier mache. The mica can be easily tinted in different colors, thus adding to the beauty of the ornamentation.

Purification of the More Easily Fusible Metals by Filtration.

If the substance of which a filter is composed has no attraction for the particles of the liquid to be filtered—i. e., is not wetted by it, the interstices of the filter do not act like capillary tubes, and the liquid will not pass through.

Mercury will not run through a very fine sieve of iron or copper wire unless the wire is amalgamated. If the wire be amalgamated, although the meshes be very fine, the mercury will pass through, easily, while any pieces of iron, copper or amalgam will be retained on the filter. Lampadius, formerly Professor of metallurgy in Freiberg, has attempted to make use of this principle in purifying easily fusible metals, and with what success the following will show: Tinned sheet iron, as thin as paper, was cut into strips six inches long and four inches wide. Five hundred of these were placed face to face and fastened in an iron frame, with wedges driven in to bring them closely together. This frame was lifted into the bottom of a graphite crucible. Some impure Bohemian tin was melted in another crucible, and allowed to cool until crystals began to form on the surface, when it was dipped into the filtering crucible. The tin which was still fluid, ran through almost chemically pure, while a pasty magma remained on the filter, which contained iron, arsenic and copper chemically combined with tin.

SULPHUR AS A FIRE EXTINGUISHER.—*Les Mondes* suggests that brimstone should be carried on board every ship for use in case of fire. Half a hundred weight (30 kilos.) of brimstone would be sufficient to abstract the whole of the oxygen from 3,531 cubic feet of air, thus rendering it unfit to support combustion. In a closed space, like a ship's hold, the sulphurone gas produced by the burning of the brimstone would penetrate where water from the decks could not be brought to bear, and the density of the gas would prevent its rising or spreading if care were taken to close the hatches with wet sails, etc. It is suggested that the brimstone should be made up in the form of large matches, the ends of which could be passed through scuttles prepared for them in the decks or bulkheads in case of need. It is asserted that \$4 or \$5 worth of brimstone would be sufficient to stifle and annihilate all traces of combustion in an air space of 35,000 cubic feet.

In connection with the above we may remark that chloroform vapor has been lately found by a chemist in Antwerp to act with great rapidity in extinguishing the flame of the vapor of petroleum. Combustible gases mixed with chloroform vapor immediately lose their explosive properties, and even their combustibility. It is suggested that chloroform might be advantageously employed upon a large scale for extinguishing fires in petroleum stores and on board ship.

A SIMPLE GLYCERINE THERMOMETER.—This instrument, suggested by A. Jaksoh, of Bohemia, is made as follows: An ounce bottle is two-thirds filled with glycerine of any desired color, and the bottle placed in a freezing mixture of sal-ammoniac, saltpetre, and water, so as to cool the liquid to 32°F. A glass tube twelve to fifteen inches long is passed through a good fitting cork, so as to dip nearly an inch into the glycerine. The cork is inserted in the bottle and rendered air-tight with sealing wax or a cement of varnish and chalk, and the thermometer is then ready to be graduated. On inserting the cork, the liquid rises in the tube a few inches. The bottle is placed in melting ice, and the level of the liquid marked 32°, if the scale is to be Fahrenheit's. It is next placed in warm water, say at 132°, and this point marked. The space between these points is divided into one hundred equal parts, and this division carried down to the Fahrenheit zero, and upward to the top of the tube.

NEW PROCESS OF GILDING ON GLASS.—Prof. Schwarzenbach, of Berne, has recently devised the following new method of gilding on glass: Pure chloride of gold is dissolved in water. The solution is filtered and diluted until, in twenty quarts of water, but fifteen grains of gold is contained. It is then rendered alkaline by the addition of soda. In order to reduce the gold chloride, alcohol saturated with marsh gas and diluted with its own volume of water is used. The reaction which ensues results in the deposition of metallic gold and the neutralization of the hydrochloric acid by the soda. In practice, to gild a plate of glass, the object is first cleaned and placed above a second plate slightly larger, a space of about one-tenth of an inch separating the two. Into this space the alkali solution is poured, the reducing agent being added immediately before use. After two or three hours repose the gilding is solidly fixed, when the plate may be removed and washed.

NITRO-GLYCERINE.—Professor Mowbray, in a recent lecture before the Stevens Institute of Technology, on the subject of explosives, stated that nitro-glycerine is now largely made from the fatty waste of stearine and soap factories. Its density, which is 1.6, water being 1, enables it to exercise its tremendous force; for, in a given bulk, there is 60 per cent. more gaseous matter than would be contained in it were it only of the density of water.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

BUTTE.

KENT BAR MINING CLAIM.—Oroville *Mercury*, May 7: We learn from Deputy Sheriff Stevens that extensive preparations are being made for mining in this claim during the coming season. The long spell of dry weather, it is thought, will make the river low enough to mine any part of it without serious trouble before the winter rains come again. A large number of men will be employed. Prospects have revealed the fact that the claim is full of good pay dirt, and the owners are confident of taking out something handsome. This is only one of a number of like enterprises that will be undertaken during the coming season.

CAVED ON.—One day last week, as William O'Connell was working in the mines at Cherokee Flat, in this county, he was caved on and one of his legs broken in two places, and the other in one, besides which he received internal injuries that were thought to be fatal. Last Friday he was brought to town and sent below to the Bay where he will become an inmate of St. Mary's hospital.

CALAVERAS.

REN HILL.—Calaveras *Chronicle*, May 8: The work of washing up the tailings, at the Red Hill hydraulic, is completed, and piping gravel commenced last Tuesday. The mine is now in first-rate order for working to good advantage, and operations will be pushed energetically forward as long as the necessary amount of water can be obtained.

IRON ROCK STRAOK.—The pay chute has been struck in the 100-ft east level of the San Bruno mine at Mosquito gulch. The rich ore was uncovered twenty ft from the shaft. The ledge shows about its usual thickness—two ft. Stopping will be commenced as soon as the level is driven far enough ahead to admit of it.

RELOCATED.—We learn that parties have relocated the old What Cheer claim, in Chili gulch, and are making preparations for working it. A good deal of money has been expended on the mine in days past, but the ground has not yet been thoroughly prospected. There is considerable water to contend with in working the claim—so much that machinery will be necessary to keep it out. The What Cheer is located on the "blue lead," a channel that can only be reached by sinking a shaft or running an incline. The present locators of the ground, however, will have nothing to do but to put up machinery; free the old works of water and go to taking out gravel. Former owners of the mine ran an incline that a little repairing will put in good condition. The new enterprise has good prospects of success.

THE PIONEER CHIEF.—Calaveras *Citizen*, May 8: During the past week a party of Eastern capitalists have visited San Andreas and examined Sheriff Thorn's quartz mine, described in his U. S. patent as the "Pioneer Chief," with a view to negotiating a purchase. After a thorough examination of the mine they expressed themselves highly gratified with the results obtained from prospecting as well as with the location of and general appearance of the lode. There is no doubt in regard as to the genuineness of the lead. It is a true and rich vein, and when properly developed will prove one of the best paying mines in the State.

FRESNO.

THAT QUARTZ MINE.—Fresno *Expositor*, May 10: Last week we mentioned that Messrs. Jensen & Keyes were about to erect a four-stamp water power mill, on a quartz lode on the Rose-lawn farm. Since then we have learned from Thomas Whitlock some additional particulars regarding the mine. The ledge has been prospected by means of an inclined shaft, following the slope of the ledge, to a depth of thirty feet. At that depth the ledge has attained a width of three feet. The walls of the ledge are well defined. The gold is fine, hardly perceptible to the naked eye, and seems generally diffused through the ore. Several small lots have been tested by working process, and found to yield handsomely. The ledge has been traced some miles, and several claims have been located on it. Messrs. Cartwright & Smith own one of the most extensive claims, and they have made some very satisfactory discoveries.

INYO.

PANAMINT MINING ITEMS.—Panamint *News*, May 4: We called on Captain Bell yesterday morning to interview him in regard to mill and other matters and found him more enthusiastic than ever over the bright prospects for Panamint, since his return from San Francisco. He says the work on the twenty-stamp mill will be driven ahead as fast as possible, and as soon as this one is running, work on the lower mill will commence. The lower mill will be supplied with a Bruckner revolving cylinder, or roaster. When this is done the company will immediately commence the erection of a sixty-stamp dry crushing mill, with two Statefeldt furnaces, on their mill-site on Stewart's Wonder Point, just above the Jacob's mill. The company have secured the right for the Statefeldt in Panamint and Rose Spring districts. They have also given orders for the manufacture of five hundred thousand bricks, instead of two hundred thousand, as first determined upon. It will be seen by the extent of the above operations by

the company, that a large number of men will be needed, and Captain Bell authorizes us to say that good carpenters and millwrights can now find employment, at good wages, for several months to come. In addition thereto the company will, in about ten days, put a large number of miners to work in their mines, taking out ore. The Captain is now engaged in setting four immense boilers for the upper mill, and will soon have things in such shape that a large number of bricklayers can be worked advantageously.

SUNNYSIDE.—Among the mines that will soon occupy a prominent position with the best of those in this district, we note particularly the Sunnyside, situated in the same mountain ridge as that of the celebrated Jacob's Wonder, but being some 500 feet lower down, running parallel to and beginning at the southwest end of that mine. The vein is well defined and shows in no place a width of less than four feet, all the croppings showing ore of a high grade. The ore chute of this mine is the longest of any we have seen in this district. The mine is owned by James F. Ward, of Los Angeles, an old, experienced prospector and miner, who has made his wealth by legitimate mining.

THE SUNRISE MILL AND MINING COMPANY.—Having commenced work but four or five days ago, in sinking a well for water on their mill site, have succeeded in striking a fine body already. Work in clearing and otherwise preparing the ground progresses rapidly. Their machinery and lumber are expected to commence to arrive at any day, and it would not surprise us to see this company turn out the first bar of bullion in Panamint.

DARWIN DISTRICT ITEMS.—Cor. Inyo *Independent*, May 8: Since my last items to you there have been several changes of ownership in some of our most prominent mines. Mr. C. E. Hoffman, of Santa Clara, has bought the "Lucky Jim," and Mr. G. D. Roberts, of San Francisco, has bought Bill Gill's interest in the "Christmas Gift." Mr. Roberts is now one of the largest mine owners in this district. I understand that the intention of these parties is to commence developing their mines immediately, and that Mr. Hoffman will return here in two or three weeks, for the purpose of building a furnace. Mr. H. is a gentleman of long experience in the furnace business, both in this country and Europe, and I think from his actions while here that he means business. Being a practical assayer, he has sampled and assayed ore from most of the mines in the district, and is well satisfied with the result.

MODOC.

NEW MINES.—Modoc *Independent*, May 1: Considerable excitement prevails in Surprise over the newly discovered mines. The ledge is situated in the Surprise valley range of mountains and an easterly direction from Dorrisville. Some of the ore has been sent below for a test, and it is from the favorable reports recently received the excitement began. Many locations have been made along the croppings for about ten miles. Every test so far made is of the most flattering character. New locations are being made every day and many are now sanguine of developing rich mines in Modoc county.

MONTEREY.

QUICKSILVER.—Salinas *City Index*, May 1: Another quicksilver mine has been discovered in this county. It was found by B. F. Dillard, of this city, one day last week. It is located in the mountains, about six miles south of this city, and is said to be rich. The specimen looked like the pure stuff.

NEVADA.

GASTON RIDGE.—Nevada *Transcript*, May 8: A. J. Pelham & Co., who for the last six or eight months have been running a tunnel on the old Gaston Ridge mine, about six miles above Washington, and about the same distance from Eureka South, were rewarded on Friday last by striking a splendid ledge of very rich rock, which, according to the judgment of experts, will pay \$200 per ton. Many years ago this mine was worked somewhat extensively and a chute of very rich rock followed several hundred feet. This rock was milled in the old California mill, which being destroyed by fire about the same time the pay chute of rock pitched below the water level, work was suspended and owing to disputes in the company, was never resumed till Mr. Pelham and the present company purchased it, when they immediately started a tunnel about 125 ft lower than the old works, upon which they have been steadily employed ever since. They have now tapped the ledge over a hundred feet deeper than the old works, and the presumption is that they have at least 100 ft of rich "bocks," between this point and the bottom of the old works.

NEBRASKA MINE.—The Wood brothers have been for a year or more prospecting in the Nebraska mine, with the view of striking the ancient river channel which runs through on the east side of Sugar Loaf mountain. We understand they have at last found it, and the gravel is very rich. They have labored under very discouraging circumstances, such as would have made less resolute persons abandon the enterprise long ago. They are deserving of success, and from all we can learn, they are sure of it now. The success in this mine will encourage others located on the channel to persevere until there is a succession of mines all along where the channel is known to run between Sugar Loaf and Cement hill.

HOWARD HILL.—Foothill *Tidings*, May 8: The work of pumping out this mine has been

going on for some time and we understand is expected to be completed early next week, when regular mining operations will begin.

THE HARRINGTON GRAVEL MINING COMPANY, whose property is on Alta Hill, adjoining the Picayune mine, have their tunnel retimbered and will soon be driving ahead again. They expect to reach the channel with about 200 feet of tunnel. Those well posted on gravel think this a splendid property.

NEW YORK HILL.—Things at this mine are fast assuming shape. The building over the new hoisting works is completed, most of the machinery is set and it is expected that connections will be made so that steam will be raised on Tuesday or Wednesday next.

BUCKHAM MINE.—This mine is located southwest from Grass Valley, near Bear river. The location was made years ago and the ledge has been worked with good success. The rock had to be hauled to Grass Valley in order to have it tested, and it has been worked through two or three different mills, in different lots. The ore has paid all the way from \$15 to \$29 per ton, by mill process, and without estimating sulphurets. The average of all the ore worked has been something over \$20 a ton. The ledge averages over two feet in thickness, and has been tested to the depth of ninety feet. A letter from J. G. Worthington, received yesterday from the Buckham mine, states that the rock is improving rapidly in the shaft, showing free gold (a thing that has seldom been seen in the rock which has been worked) and plenty of sulphurets. The mine only needs a mill on it to prove a success. This thing of hauling quartz from ten to fifteen miles is not economy. The owners are men without capital and they would like to arrange for a mill. They can show the certified figures for the yield of the rock, and from the best and most careful mill men in this district.

PLACER.

GREENE MINE.—Placer *Argus*, May 8: The Greene mine cleaned up this week about \$7,000 from a run of 35 days. The rock crashed averaging a little over \$21 to the ton. This mine is in excellent running order, the machinery being complete and of the most approved patterns. Mr. Greene, the superintendent, informs us that the prospects are flattering. New chutes are being developed that promise rich pay.

THE ST. PATRICK cleaned up \$5,000 from 300 tons of rock. The 440, 360 and 212-ft levels are looking well and improving, with every indication of producing abundant rich rock. This mine has more than paid expenses this month, and the prospects are that it will continue in the future, as it has in the past, to be a paying one, at least this is the determination of the present superintendent, who thoroughly understands his business.

THE GOOD FRIDAY mine, under the indefatigable exertions of its present superintendent, J. M. Bryan, has been rewarded by striking very rich rock, where gold predominates. The future prospects of this mine are very flattering.

THE ST. LAWRENCE mill and mining company have on hand over 100 tons of rock, from which they expect handsome returns. They started up their mill on Thursday.

THE HOTELS are crowded, many miners are prospecting, and everything looks prosperous and encouraging in the Ophir district.

FURTHER COAL DISCOVERIES.—H. Stone showed as a specimen of Cannel coal, the surface croppings of a vein discovered by Mr. Crombie, about ten miles from here near Wolf creek. Mr. Stone, who is thoroughly posted on coal, pronounces it superior, he thinks, to that taken out at Lincoln in this county, although he has not given it a practical test. The extent of the vein is unknown, but the discoverer expects to find it in paying quantities.

GOOD RUN.—Placer *Herald*, May 8: The Enterprise hydraulic mining company, of Iowa hill, in which our townsman, Judge Spear, we believe, is largely interested, cleaned up about a week ago, after a nine days' run, about \$2,000. This is something over \$200 per day, which, when we consider the almost everlasting character of these mines, is very good indeed, and indicates plainly, we think, the great wealth that district will produce as soon as the arrangements for water supply are perfected. The Iowa Hill canal is now near enough completed to bring in quite a large supply of water, but owing to an accident that occurred to the main reservoir this last winter, they have not been able to turn this water to full account. This accident is, we learn, about repaired. It is estimated that with plenty of water this district is capable of turning out \$300,000 a year, at least.

THE JULIAN mine at Jenny Liud Flat, below Newcastle, is running steadily, with good results. It is one of the substantial mines of the county, and is opened up in such shape that rock is taken out fast enough to keep its 20-stamp mill running continually. About thirty men are employed in and about the mine, and for several months the mill has never been stopped, only to clean up. The average daily crushing is about twenty-five tons, and the average yield of the rock is about ten dollars. The ledge maintains an average width of about four feet. This mine is the property of C. H. Schnabel.

THE AUBURN gravel mining and ditch company are driving the work on their new ditch in a lively manner. The main ditch is far advanced, and the small ditch, in which the large twenty-two-inch pipe is to be laid, is almost completed, and the work of laying the pipe on the ground has commenced. The tunnel on the line of the new ditch is in something over fifty feet.

PLUMAS.

SOLD OUT.—Plumas *National*, May 8: We learn that the Hallsted Brothers have recently disposed of their mining claims at Kingsbury Ferry, above 12-mile bar, the East Branch mining company purchasing, for the sum \$10,000. The ranch, houses, etc., were a part in the sale. The new company propose to pipe the water from Kingsbury's creek across the river and raise it to a sufficient height to obtain pressure for their giants, and if report is correct this can be done at a small expense, compared with some of the water projects now operation in this county. The claims are known to be rich and extensive, and the investment promises to be a paying one.

MINTO ITEMS.—The North Fork company are cleaning up and the results are astonishing the owners. One box yielded over fifty ounces. An extract from a letter from Dm hill says: "The yield surpasses our most sanguine expectations. Gold, gold everywhere. Pierson & Winter are still making big wag in their gravel claim under the bluff, in Nelson, and the claim promises to be extensive."

BIO STRIKE AT GIBSONVILLE.—"Shep," La Porte mail carrier, informs us that the Union company, whose claims are located by Gibsonville, have recently struck it rich and the best part is, it proves the existence of the big blue lead under the main ridge, a will cause the owners of the adjoining claim to drive ahead their works, with a certainty being rewarded for their toil. The Union company washed up fifty-three ounces from car-loads. There are sixteen shares in the claim, and the owners are jubilant, feeling certain of a fortune. The chances are now favorable for Gibsonville to regain all its lost gold and come back to the lively time of two years ago. The owners in the Union are entitled to credit for their perseverance, having run their main tunnel over 3,000 ft, and that, without being positive that they would pay. We hope the strike may make rich many of all of them.

SANTA CRUZ.

FIAT CLAY.—Santa Cruz *Sentinel*, May 8: It has been whispered here that very large body of fine clay, suitable for making fire brick, has been discovered on the Chonero ranch east of the San Lorenzo river. Parties are now negotiating to commence manufacture of fire brick. The clay is similar to that found at the Mount Savage iron works near Cumberland, Md.

BLUE CLAY.—Last week we noted the discovery of a large body of bi-carbonate of lime on the Dodero farm and below Mrs. Major's house. This week, we are informed that inexhaustible body of the Benicia blue (necessary in the manufacture of cement), has been discovered in Week's leegoon, west of Blackburn's orchard and in Corcoran's lagoon on the line of the Santa Cruz and Pajaro road. Now let the old Major's mill be at or utilized to grind the cement. Firewood burn the cement can be procured and delivered at the mill for \$3.50 per cord, and probably at \$3 when the San Lorenzo railroad is completed. Staves for barrels, headings, hoops, etc., can be procured in the woods within five miles of the works. This new branch of business will, in time, give thousands men employment in this county.

SIERRA.

NORTH FORK.—Mountain *Messenger*, May 7: The North Fork company have gravel in the tunnel. The gravel prospects in fine gold are getting coarser as they go ahead.

BONDED.—The Bald Mountain company have bonded their mine for a large sum. It is said the buyers will get a very valuable property.

It is said that the South Fork company has struck gravel in their tunnel.

YIELD.—The Empire company, of Monte Cristo, took out 115 ounces of gold for the day's run with nine men in April. This is equal to about fifteen dollars per day to the men. The company are unable to work more men want of water.

NUCKET.—A nugget weighing over \$1,000 was taken out of the Bald Mountain claim on Monday last week. The night foreman, during the shift one night recently, took out thirty ounces with his candlestick. Hard to be beat.

SISKIYOU.

IRON AND COAL.—Yreka *Journal*, May 5: One of the greatest advantages of a railroad to the Siskiyou county would be the development of extensive iron mines in various parts of the county, a probably coal mines. While all the mountains on the west side of Shasta valley contain quartz, nearly all the mountains on the east side contain iron and coal. Mount Shasta itself is a great iron mountain, and no doubt contains much coal, but it is useless to work without a railroad to transport the ore to smelting works. Out at the Oregon elbow north of town, is also a well developed iron mine, of as handsome ore as a person would desire, and all over the flats around this town can be found any quantity of kidney ore, which is the very best quality of iron. If that Eastern company puts up the proposed smelting works at Sacramento, and the railroad is tended to this county, the iron fields of this section could supply it with raw material generations to come.

In this vicinity are vast tracts of mine land that could be taken up by the settlers in twenty-acre blocks, and patented for mining purposes; which land besides being used for mining purposes could be used as a homestead and farm. There are thousands of acres of this kind of land in all the mining districts

the county, very little of which is occupied, and if ditches or artesian wells could be built, furnish water every man settling on such land in many places could secure a good mining claim and farm combined. Quartz claims could be taken up with a similar privilege, though the locator would not be as liable to ad good soil covering quartz claims as often over placer diggings.

AN BENITO.

Moaz QUICKSILVER.—San Benito Advance, May 8: The quicksilver developments near the head of Cholame valley are very promising. R. Pitte, who is working in connection with the San Francisco mining company, has already excavated a pile of ore valued at over \$100,000. Messrs. Lee & Spencer are very much encouraged by the rich assays made from the corries, a mine which promises to be as rich as cinabar as any in the State.

UOLUMNE.

NEW ALBANY MINE.—Union Democrat, May 8: The owners of the New Albany mine are engaged in constructing a ditch and flume two miles in length, to bring water to the mine for filling purposes. There is a force of twenty men at work. It will be pushed forward as fast as it can be and the lumber required is secured and furnished. The mine is developed enough to justify the erection of extensive works; no time will be lost in getting up a mill of other improvements to put it in proper working condition. Dr. Walker, the superintendent, has first found there is a mine before making expenditures for machinery and appliances.

QUICKSILVER has been talked about this week. Ore claims were recorded in the Marsh Flat section, and Jack Knowles came down from the mountains with some specimens he took near the summit of the Sierra. He went through the snow, found the vein, traced some 1500 feet. Parties from the other side reported to have been over but were unsuccessful in finding it. When the weather allowed snow will permit, thorough explorations will be made, and if cinabar in paying quantities is lying in the mountains, it can hardly escape being found this summer. There is much faith with those engaged in prospecting Marsh's Flat that something valuable will be developed there.

TRINITY.

STUBBORN IT GOOD.—Trinity Journal, May 8: The Bowermen was in town this week and learned that Muncey & Reed have opened a claim on Buckeye creek, at the mouth of Dutch John, which is paying them well. Water is scarce, they work it by shoveling into all boxes, and in this way they realized an average of a day to the hand last week. On Wednesday last they picked up a nugget weighing nearly \$200. Such items are particularly interesting these dry times.

FROM CINNABAR.—Under date of May 2, our faithful Cinnabar correspondent furnishes the following interesting and cheering intelligence: "Butler & Hawlett are working in their second level, and have richer ore than they have heretofore worked, the ore seeming to get better as they go down and the stringer wider. The stringer at the present time is from 16 to 18 ft in width. They are opening three breasts and expect to be able to keep their retorts running day and night. They are taking out, from their retorts, from five to six tanks of quicksilver daily. Butler & Worland are getting very rich ore out of their shaft, and as soon as they get their furnace completed expect to take out quicksilver in paying quantities."

CLARE.

BUALHIGH DRILL.—Visalia Delta, May 8: We learn that Mr. Brown, the superintendent of the New England mining and smelting company, is about to introduce the Burleigh drill the Mineral King mines. "It is to be employed in running a tunnel from the bed of the wet fork with a view of tapping all the principal leads of the district, in all of which this company possesses more or less interest. The machinery is to be worked, we believe, by hydraulic power."

Nevada.

ASHOE DISTRICT.

CALIFORNIA.—Gold Hill News, May 6: All the cross-cuts eastward on the 1500-ft level are being steadily advanced with the exception of Nos. 1 and 2, there being no material change in the report of them. Sinking the winze from the 1400 to connect with the 1600-ft level is making steady progress, the bottom still in ore. **OPHIE.**—There is no change of material value either the look or yield of the ore stopes on the 1465-ft level. The northeast winze on the 65 ft level has been sunk to the depth of 85 ft the bottom still in good ore.

CONSOLIDATED VIRGINIA.—The joint prospecting cross-cuts on the 1300 and 1400-ft levels are steadily advancing, without change of interest to record. Work has not yet been resumed on the 1550-ft level. Everything in and out the mine is working finely, and its future looks more prosperous than ever.

BULLION.—The quartz and ore in the face of a drift on the 1700-ft level of the Imperial shaft is of a very solid and encouraging character. The further the drift is driven the more settled becomes the conviction that the ledge at this point is large and well defined and of a most promising character. The quartz body on the 800-ft level continues to develop rapidly, but as yet affords no bodies of paying ore.

CROWN POINT.—Daily yield, 550 to 600 tons ore. The ore breasts throughout the mine are looking finely, and show no signs

whatever of giving out. Prospecting the 1600 and 1700-ft levels is still vigorously prosecuted, with some favorable indications of ore developments ahead on the 1600-ft level.

HALE & NOBACROSS.—The steady and persistent prospecting of the 2100-ft has developed nothing new during the past week. The cross-cutting of this level has been very thorough, and although considerable quantities of quartz have been encountered no paying bodies of ore have been found. Preparations are now being completed for sinking the main incline 200 ft deeper, at which point the ledge will be again cross-cut and prospected.

SIZAAA NEVADA.—Sinking the old shaft is making the usual good progress, the rock in the bottom working soft and favorable. Driving the east drift on the 700-ft level is making steady progress, the face still in a very encouraging character of ledge material.

BELCHER.—The water is being rapidly drained from the main incline, so that work can be again resumed on the 1500-ft level in a very few days more. The north and middle winzes from the 1400-ft level will reach the 1500-ft level in a day or two more, the bottoms of both being still in ore. Daily yield, 450 tons of ore. The ore stopes are all looking well throughout the mine.

EUROPA.—The quartz in the face of the drift or cross-cut east from the winze, 113 ft below the adit level, continues of the most favorable character. It is low-grade ore, but there is a good solid body of it, and valuable deposits of ore may be looked for before long.

CHOLLAR-POWELL.—Sinking the main incline is resumed, and is making good progress. The main south drift on the 1500-ft level is at a distance of 420 ft, the face in porphyry. The main south drift on the 1150-ft level is in 250 ft, the face also in soft porphyry. Daily yield, 36 to 40 tons of ore from the old upper levels, the assay value of which is \$28 per ton.

ORIGINAL GOLD HILL.—This mine is at the present time looking better than ever before. The air-pipe just introduced throughout the north drift, at the 340-ft level, gives good ventilation and excellent facility for driving ahead. A second cross-cut from the south drift is being made into the ore body, and shows very good milling ore. The new ore dump is about completed.

SURRO.—The rock in the face of the main west tunnel, which has been very hard for the past three weeks, is gradually softening, and shows evident indications of a near approach to the ledge.

AMAZON.—The shaft is sunk and thoroughly timbered to the depth of 96 feet. This shaft is being sunk at the foot of the mountain, 100 ft below the surface cropping of the ledge, so that a drift started at the 100-ft station will cut the ore vein at a depth of 200 ft below the surface and will open the mine at a depth of 100 ft below the bottom of the old works.

LEO.—Sinking the winze below the main east tunnel level is progressing at the rate of two feet per day. The vein matter shows a steady improvement, the clay being of a deeper blue color and the quartz of the white Comstock character, with occasional seams of ore showing free gold.

GOLIN & CURRY.—The new pumping machinery is all working splendidly, and the water has been drained to the 1700-ft level, at which point work has been again resumed in the north drift, which will connect, in a distance of about 80 ft more, with the south drift from the Best & Belcher winze. Burleigh drills, driven by compressed air, are used in the face of the drift, and good progress is being made.

SAVAGE.—The steam was turned on the new incline hoisting and pumping engine day before yesterday, everything working as smooth and perfect as it was possible to have it.

JULIA.—Sinking the main shaft is making fine headway; the Burleigh drills working well, and the rock in the bottom blasting splendidly. Driving the main south drift on the 1000-ft level is making steady headway.

NIAGARA.—Sinking the shaft is making splendid progress, following the foot-wall of the ledge, occasionally cutting bunches of excellent ore.

BUCKEYE.—The east cross-cut on the 550-ft level has reached the east wall of the ledge, and is stopped for the present without finding any milling bodies of ore. A drift has been started to the northward on a streak of quartz cut in this drift, the streak gradually widening from one to four feet as the drift progresses, the whole vein being ore that will assay from \$12 to \$30 per ton.

BEST & BELCHER.—Driving the main south drift from the bottom of the winze on the 1700-ft level, to connect with the north drift from the Gould & Curry shaft, is making good progress, the Burleigh drills used in the face doing good execution.

BALTIMORE AND AMERICAN FLAT.—The cross-cuts on the 700-ft level are showing a decided improvement in the quality of the ledge material penetrated. The cross-cut on the 850-ft level are also showing improvement.

YELLOW JACKET.—Driving east toward the ledge on the 1840-ft level is making excellent progress. The drift is now in a distance of 100 ft, and will have about 80 ft to run to reach the ore vein.

SILVER HILL.—The water has been drained and sinking the shaft resumed, the sinking making excellent headway. The new pumping machinery is all working finely.

LADY BRYAN.—The water is drained to the 380-ft level, and will now, soon be sufficiently overcome to admit of a resumption of work on that level.

SOUTH COMSTOCK.—Shaft now down 173 ft, and sinking in ledge matter, with quartz which gives fair assays. Milling ore is evidently not far off.

DATTON.—Building the mason work for the engine beds, and putting in the anchor and engine bolts, has made good headway during the past week.

IMPERIAL-EMPIRE.—The east cross-cut on the 2000-ft level has cut through the clay wall and is showing much more favorable indications than for some time past. Sinking the main incline is making steady progress.

LADY WASHINGTON.—Grading for the heavy new machinery is getting along finely, the excavations for the foundations of the pump engine and bob being nearly completed. The mason work will be commenced next week.

PHIL. SHERMAN.—The rock in the face of the main west drift works softer and better, and more clay and quartz seams are coming in. Quite a promising and important change seems to be taking place.

MEXICAN.—A chamber is being opened in the north drift on the 1465 ft level for the purpose of commencing to sink a winze on the ore body recently developed at that point.

CORNUCOPIA DISTRICT.

THE LEOPARD.—Cor. Virginia Enterprise, May 9: In speaking of the Leopard mine, a writer says: "This mine is certainly very rich, and will prove a good one after a time. They have the ledge in a tunnel at a depth of about 150 ft, and it certainly looks splendidly. It is the only mine at present which is taking out ore. There are several other mines prospecting. What is wanted now is another mill with a large run of stamps. The one we have is only a ten-stamp mill, and it is kept constantly at work, crushing Leopard ore. The consequence is outsiders have no opportunity of crushing rock. Another drawback is the scarcity of wood. There is none nearer than 17 miles. The mill is compelled to burn sage-brush for fuel. From what I have seen of this section, I think it is a very good place to prospect in. Almost every mountain is covered with quartz, and now is the time to prospect, as the snow is all off the mountains."

Idaho.

NEW MINES—OWYHEE.—The Owyhee Avalanche, of May 4, referring to the newly discovered placer diggings at Wagon town, ten miles below Silver City, says: The hills in which the precious metal has been discovered are a short distance from Tom Wall's house, and the belt of ore is supposed to extend through to Trout creek, a distance of ten miles. Prospecting thus far has been attended with the most favorable results. J. B. Jones, hearing of the excitement yesterday, rode quietly down there, took a survey of the country at daylight this morning, and made up his mind to secure the water right. Two other parties were already en route to Silver on the same mission. Jones passed them on the road, making speed at the rate of twenty miles an hour, and got to the Recorder's office first, securing his title. Mr. Jones believes the diggings are worth a million dollars. If they continue to develop as they look thus far, active work will soon commence.

There are rumors on the street of a very rich and important strike which has been made within a day or two at the Pauper mine. The ore is entirely different from any yet seen in this camp, and bears a striking similarity in appearance to that of the great Comstock lode of Virginia, so much so that samples placed together cannot be distinguished from each other. Tests are being made, and the indications are that it will assay from \$250 to \$700 per ton.

Utah.

MINING MATTERS.—Reports from the eighty-six mining districts in Utah Territory are very favorable, considering the difficulties the miners have had to surmount in the way of late snows, slides, and high water. The settled weather is causing many to resume work on prospects which have been lying idle during the winter. The producing mines in several of the leading camps have been making their regular shipments to the mills and smelters, and have been increasing their facilities for more thorough developments. The outlook for greatly increased production over that of any previous year is very promising, and the yield of precious metals for 1875 may, the Salt Lake Tribune thinks, safely be set down at \$9,000,000.

HEATING IRON WIRE.—An anomalous and remarkable change takes place in the heating and cooling of iron wire. While the iron is first heated there is a sudden contraction or cooling; and so again, when the heat is cut off, the wire cools a little and then suddenly reheats and glows, afterwards quietly passing down to a blackness. Professor Barret, of the Royal Society, explains the notable points in the jerks or changes, by stating that the iron in the first instance loses its magnetism and in the last jerk or oscillation regains it.

DELICATE RADIOMETER.—At the last annual soiree of the Royal Society, Mr. Crooke exhibited some simple delicate radiometers. These consisted of a glass stem supporting a little four-bladed windmill, carrying four discs, one on each end of the four slender glass rays. These work horizontally, supported by a steel point on a small topaz, and the radiation of light from a common candle at some distance away suffices to make them rotate with great liveliness in a vacuum in a small glass globe.

Steam Launches.

Steam launches have become so much the rage in England within the past few years, and so many are built, that there is great competition among the marine engineers as to who can get the greatest amount of speed out of the smallest possible amount of machinery. The English builders have become very expert in this class of work, and are far ahead of our people. Boats are made now to attain a marvellous speed with so light a draft of water as to seem only to sit on top of it. Many of the water courses upon which these little craft are used are very shallow in places, but the long flat boats, with double propellers, overcome this obstacle readily.

Of course in such diminutive specimens of marine architecture as these little launches every inch of room is desirable, and therefore it is necessary to keep the boiler and engine in as compact a form as possible, so that there will be room for passengers. Moreover, as a high rate of speed is one of the requisites, considerable steam surface is wanted, which is hardly compatible with small boilers. The engines, too, must be small and compact, with as little gear as possible, and improvements are being constantly suggested to combine all the requirements of this class of boat building.

We notice in *Iron* a description of the latest of these improvements, in the shape of a very compact little engine to drive a single screw, the invention of P. W. Willans, of the factory of John Penn & Sons, marine engineers at Greenwich. It was built for a boat where, as usual, large cabin accommodation was wanted, and therefore the engine was wanted to set very far aft; so far back, indeed, as to render the use of the usual yacht engine impossible.

This little engine is constructed with three cylinders, and the only working parts are three pistons, three connecting rods, and a three-throw crank axle. These are enclosed in a cast-iron casing, so that nothing can be seen of the engine itself except the two ends of the axle wheel, which appear through the casing. The cylinders are placed side by side, and it is by a system of ports which connect the cylinders with the other, together with a peculiar construction of piston, that the piston of one cylinder acts as a slide, and admits steam to the next or third cylinder. All of these ports meet in a three way cock, and by turning this cock the direction of the steam is altered, and the engine is stopped or reversed with marvellous rapidity. It will thus be seen that all slides, eccentrics, link motion and other complicated reversing gear are done away with. There is no exposed machinery to catch the clothing of persons passing, no oil or grease flying about, and none of the other disadvantages which make steam engines in small boats disagreeable. Besides this, the engine is so simple that it is completely under the control of any one, and is so compact that it can be lifted in or out of the boat by two men; two men can also take it to pieces, examine it in every part, and put it together again in less than an hour.

The steam in the engine acts on one side of the piston only, and as the pressure is always downward the engine is almost noiseless. By means of a very simple arrangement the engine works expensively, and cuts off at five-eighths of the stroke. Though in the particular case described more than 380 revolutions were not required, it is stated that an engine of this kind has been constructed to run up to 1,000 revolutions, and at these great speeds, by allowing a small quantity of oil to remain in the bottom of the casing the lubrication of the working parts is perfect and such a thing as a hot bearing is unknown. The diameter of the cylinder of the engine under notice is seven inches, the stroke being the same, and with ninety pounds of steam and 380 revolutions the indicator card showed a little under forty horse power. The engine weighs 700 pounds, and is fitted on a boat fifty feet long and seven feet four inches beam. The preliminary trial showed a speed of thirteen miles in twenty-five minutes. As soon as the boat is in trim further trials will be made. However, the speed spoken of is well enough, provided the engine and all are out of the way, compact and light. People would rather have a little slower boat provided they could have more room and more comfortable quarters, with no smell of greasy machinery right in the center of the boat, in front of the cockpit. This engine itself is a new move in the right direction, by getting the machinery in a small space and well out of the way.

TIDE CALCULATING MACHINE.—At the last annual soiree of the Royal Society in London, Sir Wm. Thomson's tide calculating machine was exhibited and bore off the palm of the exhibition. By means of the first one observation of the rise and fall of the tides is made daily from the shore, and the facts so accumulated are the constants, and form the basis for setting the second or calculating machine, in which a continuous wire passes over a series of wheels placed at various distances, the result being that of harmonic motion of different periods and epochs by which the year's facts can be ground out by turning a handwheel, and recorded on the paper carrying drum.

A Great Hydraulic Claim.

A correspondent of the *Call* writes as follows from Cherokee Flat, Butte county, Cal.: Cherokee is located in one of the richest mining districts in Butte county, about twelve miles north of Oroville. The town is not remarkable for its elegant mansions, beautiful gardens and grand scenery, though there are some small orchards and a few fine gardens; but the general aspect of the place is barren, and the surrounding hills are barren and rocky. Everything speaks of mines and minerals. All depends upon the mines, and the wealth produced is in the shape of gold bricks. The whole industry of the place has to do with mining.

Spring Valley Canal and Mining Company.

The sources of water supply for this remarkable mine are Butte creek and the branches of Feather river, as well as the water-shed of Table mountain. Butte creek and the west branch of Feather river furnish the entire summer supply. The former is twenty-six miles in length from the head dam at Butte creek to the extensive reservoir at Concord valley; the ditch is five feet wide on the bottom by three feet deep. The ditch, in its course, crosses two streams or deep canons, by means of iron pipes thirty inches in diameter. The first is 1,064 feet in length, with a maximum depression of 150 feet. The second, crossing the west branch of Feather river, is 3,555 feet in length; maximum depression, 650 feet. It flows into the large reservoir at Concord valley, which covers 320 acres of land.

The Dewey ditch takes its water from the head of the west branch, up in the region of eternal snows, is eighteen miles in length, and serves as feeder for Butte creek ditch, into which it empties. From the great Concord reservoir the water is brought twelve miles in a large ditch six feet wide on the bottom by four feet deep; it again crosses the west branch of Feather river in a pipe of the same diameter as those mentioned—thirty inches—but with a maximum depression of 856 feet, which is believed to be the most severe hydraulic strain which engineers have attempted to control in any enterprise of this kind. The pipe of the water company at Virginia City, Nevada, has a depression of 750 feet, but being only eleven inches in diameter, falls short in aggregate pressure to the running foot. The pipe is nearly three miles in length; the heaviest iron used is three-eighths of an inch. It has a head of 180 feet perpendicular pressure, and its greatest capacity is 2,200 inches by actual measurement, or 37,445,760 gallons every twenty-four hours. The above represents the summer supply of the company. In addition to these extensive ditches and reservoirs, they have about forty miles of ditches ranging from two feet wide and eighteen inches deep to ten feet wide and four feet deep, which furnish the mines with a vast supply during the winter months—probably increasing the supply to 5,000 inches.

The Great Claim.

Butte county has its large claims, as well as large and extensive estates. The Spring Valley company claim between 250 and 300 acres of mining ground, averaging 100 feet in depth—enough of good paying ground for fifty years to come, at the present rate of working. This extensive mine has three openings.

Flumes.

They have three miles of triple line of flume, two of which are six feet in width and the other four. They are constructed so as to shut off the water, so they can clean up any portion of either at any time.

Undercurrents.

They have also in connection with the flume twenty-four undercurrents, ranging from six feet in width to thirty.

Hydraulic Chiefs.

They have nine hydraulic chiefs or giants, the streams from which are forced out under a pressure of 250 feet of water, and they are constructing a ditch which will give them a pressure of 302 feet. These giants under the former pressure with seven-inch nozzle will throw 1,000 inches of water; six-inch nozzle, 700 inches; five-inch nozzle, 500 inches. From the mouth of this powerful water gun is projected a stream of water which is as solid as a bar of steel as it leaves the mouth of the gun, and remains so for a distance of 200 feet, or until it impinges against the face of the bank. It is said by scientific men that its force is equal to about one-tenth the velocity of a cannon ball. There the great mass of auriferous gravel, good and bad, has to start on its path through the sluices, shafts, tunnels, undercurrents and flumes, downward toward the lovely valley of the Sacramento. Think of the faith of these men. They believed in the problem before them, and it took them years of hard labor and thousands of dollars to solve it.

Gold Production.

Since the 1st of August, 1874, the yield has been \$290,548.49. Running expenses during the same period, \$144,000. The company employ from 120 to 160 laborers, and pay their hands from \$65 per month to \$4 per day.

The Company's Farms.

The tailings flowing from the mines have flowed down the channel of Dry creek, and during the winter freshets have been washed out over the lands adjoining the same, and have damaged them to some extent, so they have adopted the wise policy of purchasing all the ranches through which the creek flows. They

have now in their possession some 12,000 acres, which have cost the company the sum of \$280,000. For farming purposes this land is the cream of the country, and they are now busily engaged in protecting the same by building substantial levees, which will protect the land from any future overflow.

Diamonds.

In addition to the product of gold, the mines of Cherokee yield diamonds and platinum. About fifty beautiful diamonds have been found, ranging from about one carat to three and a half. They have been pronounced by experienced lapidaries in Boston, Paris, and Amsterdam, as first rate stones, and many have been cut and set as gems. Mrs. General Bidwell, of Chico, has a very handsome one, weighing about two carats. The greater part of the stones possessed at Cherokee were found during the earlier days, when primitive modes of mining were in operation. The present system of hydraulic washing, with its immense streams of water and gravel, flowing away so rapidly, renders a search for precious stones impracticable. But in the black sands which gather in the bottom of sluices, tons of which are shovelled out in the process of cleaning up, may be seen with an ordinary magnifying glass, great numbers of perfectly formed diamonds, varying from merest mite to almost a pin-head in size.

Platinum.

Is found in considerable quantities, but no effort is made to save it; though it does not amalgamate, it affiliates with the gold amalgam, and is brought in that shape; small lots have been gathered from time to time. The company have a pound or two in the office.

Small Steam Engines.

The demand for small motors for driving printing presses, farm pumps, turning lathes, coffee mills, washing and sewing machines, for sawing wood and for many other uses in small shops and in dwellings and on farms is very great, and is rapidly increasing. The engines most in demand for such purposes may be rated at from one-half to a full horse power.

If some person would make such an engine and boiler, that could be sold at a reasonable price, large numbers could be sold; as they would be used by amateurs in or about residences. They should be as simple as possible. No money should be expended on them merely for show, such as planing or polishing parts which can be painted; but they should be strongly built, and special care should be taken to furnish ample boiler capacity, with strength sufficient to prevent accidents. Thinking persons are now convinced that much of our domestic labor can and should be done by power. It is a disgrace to our civilization that a woman should be compelled to break her back over a wash tub and board. Very few men would be willing to do the same work all day; and there is no reason why this operation, which is a combined chemical and mechanical process, should not be done by machinery; and so of many other domestic labors.

Twelve or fifteen years ago there was no manufacturer who was prepared to turn out small foot lathes neatly and compactly put together and at a reasonable price. Nearly all the foot lathes then in use were "home made," clumsy and hard working. Some one saw the need and set himself to work to devise a small, compact, easy going machine, to be operated by the foot. The result was a greatly increased demand, and neatly constructed foot lathes can now be had almost everywhere, and at prices which place them within the reach of every one. The same would follow the introduction at a low price of small, safe engines of the description alluded to at the outset of this article.

BUILDING A HOUSE IN EIGHT HOURS.—The rapidity with which American mechanics turn off work is a marvel to foreigners. This fact is true even when we leave out of the question the more general introduction of machinery for hand labor in American shops. We have a letter before us, just opened, as we write, from a French-speaking German, who is having a machine made in Paris, from the same drawings used in the construction of a similar machine in San Francisco, where he complains bitterly of the tardy progress made on account of the slow mode of manipulation there. The same is true of all European countries. Time there forms, comparatively, but a small factor, in turning out a job of work, while here it is a most important essential in all jobs or contracts. We are led to this remark on perusing the letter above referred to, just previous to our eye falling upon the following item from the *American Manufacturer*: Last year Dr. A. Mischler erected in Lancaster city, Pa., a two story brick house in ninety hours. He now proposes to build on the Centennial grounds in Philadelphia, next summer, a two-story brick house, 24 by 40 feet, in eight hours! He has arranged with Capt. Geisinger, of Reading, for the furnishing of the cornice and door and window caps, which will be of galvanized iron. The Captain will be allowed half an hour in which to put up the cornice, though he thinks he can do it in a quarter of an hour.

TUNNEL UNDER ST. BERNARD.—Another tunnel under the Alps is proposed. It will pass under the St. Bernard, and be 20,000 feet in length. The novel feature of this undertaking is that under the summit the tunnel will be widened out to make a station, and a shaft will be cut up, which passengers can be taken to a hotel on the top of the mountain.

Ancient Saws.

A writer in the *English Cyclopædia* says: "The division of wood by riving or splitting was probably the most ancient method of reducing it to pieces of convenient size and shape. If the grain of the timber were straight, this plan would have the advantage of economy; but as it is not so in general, considerable waste is occasioned by riving when the pieces are required to be straight, much wood having to be removed with an adze in order to make it so. Hence arose the invention of the saw." Saws were used by the ancient Egyptians. A saw resembling a table blade knife with a serrated edge was discovered, with several other carpenter's tools, in a private tomb at Thebes, and is now preserved in the British Museum. There is a curious picture among the remains discovered in Herculaneum, representing a carpenter's workshop, with two geni cutting a piece of wood with a frame-saw. On an altar preserved in the Capitoline Museum, in Rome, there is a representation of a bow-saw, exactly resembling in the frame and twisted cord those used by modern carpenters. This establishes the antiquity of the saw. Continental workmen to this day cling to the web-saw, with bow and twisted cord; whilst Englishmen and Americans use almost invariably the hand-saw for cross-cutting and ripping, and the back-saw for dovetail and tenon work. This is a striking instance of the difficulty of ridding ourselves from an inherited prejudice. A properly made hand-saw possesses many advantages to the artisan over the antiquated bow-saw, as may be seen in the manner of his work with one compared to that of the other. The bow-saw requires well balancing to keep it in the cut, and will only saw to the limited depth of the cross-beam; whereas a hand-saw is compact and well in hand, and will cut to any depth commensurate with the strength of the workman.

Each country excels in the manufacture of its favorite tool. Germany makes a web for piercing purposes so remarkably cheap that no one enquires or cares to ask how its fabrication is effected, and the mode of its production is unknown here. France has a high reputation for veneer-webs, mill and hillet-webs, and for small circular saws an inch or so in diameter, for cutting fine specimens of ivory and bone; also very thin circulars for sugar-cutting up to two feet that would sorely tax the skill of an English or American saw-maker to make. The French workman is great in little things, while large ones are apt to stagger him. He will make a ribbon saw that no other workman can equal; but he never makes a circular saw seven feet in diameter, such as are turned out at Sheffield.

The labor in making saw-handles has been greatly reduced by cutting out, planing, boring, and slitting by steam. This is an unhealthy branch of work, arising from the amount of fine sawdust which floats in the atmosphere of the handle-maker's rooms and is inhaled by the workmen at their work. There is scarcely a healthy looking saw-handle maker in the trade; yet few consider it but as a necessity, irremediable. Originally, in finishing a saw-handle, the edges were furnished with a hard bone and a small quantity of oil—a very fatiguing process; now they are almost universally either French-polished or varnished, which is a great protection to the grain of the wood. Fancy handles are made of ebony, mahogany, and other hard woods; but for general purposes beech wood steamed has been found to be the best.

IMPORTANT ENGINEERING WORK.—A great engineering work, the only one of the kind in France, is about to be executed at Lyons. It is that of an iron bridge to connect the plateau of Fourvières with that of the Croix-Rousse, which are two heights, like that of Montmartre, in Paris, at a distance of 300 metres from each other. This undertaking is estimated to cost about 2,800,000 francs, of which a subvention of 600,000 francs only is asked from the city. This aerial bridge will consist of three spans, the central one of 135 metres, and the two others of 70 metres each, resting on open iron columns, in a line with the houses on the quays. The platform of the bridge will be sixty-five metres above the road and nearly fifty metres above the houses. Each of the two central columns will have inside a lift by which pedestrians will be raised in two minutes, at a charge of ten centimes, to the top, whence they may reach the higher parts of the city, where they may have business. The only similar works existing in Europe are the Britannia Tubular bridge, in England, constructed by Robert Stephenson, in 1847, and consisting of one span of 539 feet and two smaller ones; that over the Conway, by the same engineer, of a stretch of 400 feet; and the bridge of Dirschau in Prussia, which has six sections of 129 metres each.

At the Gould & Curry mine the time necessary to complete the repairs to the shaft and pumping machinery, has been much greater than it was at first supposed that it would be, owing to the fact that all the old pump rods, water tanks and timbers were found to be more rotten than was supposed, necessitating their removal and the putting in of everything new, from the surface down. It is now expected that this work will be completed by Saturday next, ready to put all the machinery to work from the top to the bottom of the shaft.

Boise Basin.

Boise Basin, which at one time attained a almost world wide celebrity for the marvellous richness of its placer gold mines, is a circular depression in the southern extreme of an arm of the Salmon river range of mountains. Its surface is uneven, covered by a dense growth of pine, and traversed by numerous creeks, which empty themselves into Grimes creek, tributary of the Boise river, and the only outlet to the waters of the Basin. The Basin has a mean diameter of about 25 miles; and most of its numerous creeks and gulches were originally rich in gold. It was discovered by a prospecting party in the summer of 1862, and enormous quantities of gold, lying almost on the surface of the ground, and the wild and scarcely exaggerated stories set afloat concerning its richness, attracted to it the following year ten thousand or more people. And now a population greatly reduced in numbers, but quiet, law abiding and industrious, occupies the places of the adventurers and criminals of former times. The immensely rich surface deposits which gave to the basin its early celebrity have been worked out, and the principal mining is now done in the heavy gravel deposits in deep channels, probably little less auriferous than were the surface deposits originally mined, but vastly more difficult to work, and hence less remunerative to the miner.

As all very rich mining camps have to do Boise Basin has felt to the fullest extent the damaging depression of the necessary reaction from the feverish excitement of the flush times of '63, and has at last commenced a process of recuperation that will be lasting. The hill and great gravel beds of the basin have long been worked profitably, and attention is now being directed to our quartz ledges, many of which prospect as well that "old quartz miners," "metallurgists," "experts," and other humbugs discredit the facts until shown them, and even then seek to justify their preconceived notions by such unsensational assertions as the quartz worked is only found in "blow outs," or on the surface, or that at best the veins are narrow, and a thousand and one similar ridiculous objections. And these objections, groundless and absurd as they are, are too often coincided with by misanthropes among our citizens, who should, and really do know better. All of these prejudices will wear themselves out before much longer, and Boise and Alturas counties be regarded as the richest quartz fields on the Pacific coast. But time must work out this result just as it has worked out the change in the character of the people.

But even if it were possible for our quartz to prove valueless, there is still left in the beds of our creeks an inconceivable wealth of gold and on our hills an exhaustless supply of timber. This gold the ingenuity of man, spurred on by the greed of riches, will soon find means of extracting, and this timber the needs of Utah and Nevada already demand. A bed-rock flume, the feasibility of which competent engineers have already declared, will enable us to mine on the gold, give employment to hundreds of men and to commerce hundreds of millions of dollars now lying waste under our feet. And it will not be long before this bed rock flume will be put in.—*Idaho World.*

Extravagance in Buildings.

An Eastern paper calls attention to a result of the reckless extravagance in buildings, since the war, in the large number of empty stores and lofts on Broadway and other streets in New York. It says it is almost saddening to see so many elegant stores unoccupied; and adds, that there are hundreds of costly ornamental warehouses which no legitimate mercantile business can ever pay the rent upon in these days. It is customary to point to these buildings as proof of wealth and enterprise and prosperity; they show thrift, extravagance, and folly. Honest merchants, bankers, insurance companies, newspapers, cannot carry such enormous burdens of rent as such ornamental piles impose upon them, and thrive. The architectural mania had got the better of the public judgment.

What is true of New York is equally true of this and other cities, and indeed, the influence of the mania for extravagant show has not been confined alone to buildings in cities.

There is one good, however, that is derived from such extravagance; it makes work for those who push the saw and the plane, and distributes the money of the capitalists among those who are in need of it. Especially is this the case when extravagance is displayed in dwellings. People of small means should pay by the extravagantly furnished stores, and bestow their patronage on those of lesser pretensions, where they can buy the same goods at a less price. If the wealthy choose to pay for the luxury of extravagant stores, why let them do so, and more of their money will thereby find its way into the pockets of the needy. We don't object to extravagant stores and dwellings but we never patronize them—we can't afford it.

CARE OF A GRINDSTONE.—Do not allow a grindstone to stand in the water when not in use. Clean off all grease from tools before sharpening, as grease or oil destroys the grit. When you get a stone that suits your purposes send a sample to the dealer to select by; a half ounce sample is enough, and can be sent by mail.

BLACKFOOT, MONTANA, is terribly excited over the reported discoveries of quicksilver in large quantities in that region.

GOOD HEALTH.

Taking Cold.

If any considerate medical men wants to bring his name before the public, let him publish a series of sound rules for preventing those who will follow them from taking cold. No danger is more serious; there is none that physicians can do so very little to cure, except of course by regimen, of which the sufferers are impatient, and there is none against which the population of all classes is more reluctant to take precautions. They look upon colds as misfortunes which must come and which do not signify; and if urged to take precautions regard the adviser, even if a professional man, as slightly effeminate, or, as they express it, very much given "to coddling himself." It does not strike them that a cold wave kills as many people as a burst of cholera.

Because strong children survive a daily bath in cold water they think cold water "hardens" children in winter as well as summer; and because air and exercise are excellent things, they assume that fog is air, and a long walk in a drizzle beneficial. The very use of a thermometer to regulate the temperature of a room seems to be unknown in most houses, and you will see sedentary men sitting in a room for hours with a fire which brings the temperature up to seventy degrees, and then for hours more with the fire nearly out and the temperature at fifty-two degrees, or lower. They know, we suppose, that a sudden fall of eighteen degrees will kill off men of low vitality in hundreds; will give, perhaps, a third of mankind a "touch of the liver," and will inflict one-half the remainder on "influenza" nearly as annoying and almost as dangerous as fever; but once indoors they fail to realize their knowledge.

This contempt for the thermometer—the only trustworthy guide in fire-making—is positively perverse, and so is much of the popular notion about "hardening." For the average man or woman exposure to the weather may have a bracing or otherwise beneficial effect, but the loss is as great as the gain; and for the old, for children and for persons of low vitality, is probably greater. People will sit, not in the air, but in drafts of the bad kind, drafts for example such as come under badly fitting doors in railroad carriages, with the utmost indifference, and put themselves straight in front of a fire which would not draw if it were not constantly replenished by a stream of colder air.

The same ignorance governs much of the usual practice as to clothing. The anxious mother will protect her child's chest with a care which, if he is not consumptive and wears flannel, he does not want, and then let him run to school in shoes which, if they keep out the wet, do not when he is seated keep out the deadly chill arising from the thoroughly wetted sole. It is not water on the sole of the foot or anywhere which harms people, but the chill which the water induces, and which is as injurious through the sole of the foot as through the chest or loins.

We are not, of course, arguing that a man of ordinary health should be always watching the thermometer, or should attempt to live by rule, or should sacrifice to mere living the things without which life is worthless. But he might make his life more worthy as well as more comfortable by attending to a few broad rules for avoiding colds, which at present he habitually neglects, and which may be reduced to two easily remembered principles: The secret of temperature is even warmth, to be secured by clothing and regulated fires; and it is chill, not cold, general chill, or local chill, which encourages disease.—*Herald of Health.*

THE LESSER EVIL.—Dr. Hall advocates some rather startling ideas concerning cold air. He is most earnestly against cold bed chambers, which he says imperil health and invite fatal diseases. To this—giving a contrast of some fifty degrees between the temperature of the lungs and the air of the room—the writer ascribes frequent and fatal attacks of inflammation of the lungs, and concludes with the assertion (which will astonish some) that it is even safer to sleep in bad air all night with a temperature under fifty than in pure air with a temperature under forty. For the bad air may sicken you, but cannot kill you; while the cold can and does kill very often.

SELF-INDULGENCE.—The great foe of life is indulgence under one form or another. The letting down of the standard endangers the length of the course. To be safe one must be circumspect, prudent, rational, clear in judgment, firm in self control. To the command over his appetite a man will owe length of days; and not length of days only, not mere continuity, but that which gives to continuity, which makes prolonged existence something worthy of being called a "lease of life," and not a stretch of drowsy stupor. As vitality comes to the system it beats off its foes, and conquers one after another the advancing years.

CHLORINE GAS IN A NEW RELATION.—During the late cholera epidemic in Vienna, a remedy called camphorin was used with great success in the hospitals. It is prepared simply by passing chlorine gas into pure turpentine oil until saturated; it gives a thick, heavy, oily fluid, of brown color, with a strong smell of chlorine. This is freed from muriatic acid by washing with water. The remedy is applied by placing a portion in a fat vessel and holding it to the patient to inhale.—*Electric.*

Domestic Remedy for Nightmare.

Slight derangement of the digestive or other functions is often sufficient to occasion a temporary delirium in children, commencing during sleep and prolonged after waking. The suffering is great and the condition an alarming one to parents and friends. The mental excitement is so intense as to resist impressions from without to an extraordinary degree. It is here that the associations of smell can be used more effectively than any others to break up the morbid train. A good whiff of cologne almost always brings the little sufferer back to his ordinary world; or a little ammonia may be used. But an odor which is agreeable is probably more effective than the one which is merely pungent.

It is a common observation that mental associations are awakened by odors more than by the impressions of any other sense. In the case of nightmare the strong, familiar smell seems to break up the train of abnormal mental excitement.

It is not straying from the subject to ask if the associations of smell, such, for instance, as the odor of flowers, have ever been used tentatively in the treatment of the insane.

REMEDIES FOR COLDS.—The severest catarrhal cold can be removed in about ten hours by a mixture of carbolic acid, ten drops, tincture of iodine and chloroform, 7-5 drops. A few drops of the mixture should be heated over a spirit lamp, in a test tube, the mouth of which should be applied to the nostrils as soon as volatilization is effected. The operation should be effected in about two minutes, when, after the patient sneezes a number of times, the troublesome symptoms will rapidly disappear. A hot lemonade is one of the best remedies in the world for a cold. It acts promptly and effectively, and has no unpleasant after effects. One lemon, properly squeezed, cut in slices, put with sugar, and cover with a half pint of boiling water. Drink just before going to bed, and do not expose yourself on the following day. This remedy will ward off an attack of the chill and fever if used promptly.

USEFUL INFORMATION.

How Hot Iron May Be Handled.

About the year 1809, one Lionetto, a Spaniard, astonished not only the ignorant, but chemists and other men of science by the impunity with which he handled red-hot iron and molten lead, drank boiling oil, and performed other feats equally miraculous. While he was at Naples he attracted the attention of Professor Sementem, who narrowly watched all his operations, and endeavored to discover his secret. Sementem's efforts, after performing several experiments upon himself, were finally crowned with success. He found that by friction with sulphuric acid diluted with water, the skin might be made insensible to the action of the heat of red-hot iron; a solution of alum, evaporated until it becomes spongy, appeared to be still more effectual. After having rubbed the parts, which were rendered in some degree incombustible, with hard soap, he discovered on the application of hot iron that their insensibility was increased. He then determined on again rubbing the parts with soap, and after this found that the hot iron not only occasioned no pain, but that it did not actually burn the hair. Being thus far satisfied, the professor applied hard soap to his tongue until it became insensible to the heat of the iron; and after having placed an ointment composed of soap mixed with a solution of alum upon it, boiling oil did not burn it. While the oil remained on the tongue, a slight hissing was heard, similar to that of hot iron, when thrust into water; the oil soon cooled, and was then swallowed without danger. Several scientific men have since successfully repeated the experiment of Professor Sementem.—*Es.*

Saving is Wealth.

One great cause of the poverty of the present day, wisely says an exchange, is a failure of our common people to appreciate small things. They do not realize how a daily addition, be it ever so small, will soon make a large pile. If the young men and women of to-day will only begin, and begin now, to save a little from their earnings and plant it in the soil of some good savings bank, and weekly or monthly add their mite, they will wear a happy smile of competence when they reach middle life. Not only the desire but the ability to increase it will also grow. Let clerk and tradesman, laborer and artisan, make, now and at once, a beginning. Store up some of your youthful force for future contingency. Let parents teach their children to begin early to save. Begin at the fountain head to control the stream of extravagance—to choose between poverty and riches. Let our youth go on in the habits of extravagance for fifty years to come as they have for fifty years past, and we shall have a nation of beggars, with a moneyed aristocracy. Let a generation of such as save in small sums be reared, and we shall be free from want. Do not be ambitious for extravagant fortunes, but seek that which it is the duty of everyone to obtain—Independence and a comfortable home. Wealth, and enough of it, is within the reach of all. It is obtained by one process, and one only—saving.—*Sci. Am.*

Useful Hints.

If you get a fish bone in your throat, and sticking fast there, swallow an egg raw; it will be almost sure to carry down a bone easily and certainly. When, as sometimes by accident, corrosive sublimate is swallowed, the white of one or two eggs will neutralize the poison, and change the effect to that of a dose of calomel.

For chilblains, cut up two white turnips, without paring, into thin slices; put the slices into a tin can with three large spoonfuls of lard; let it simmer slowly for two hours, then mesh through a sieve; when cold spread it on a soft linen cloth and apply to the chilblain at night.

Milk for breakfast, when used in the form of bread and milk, should never be boiled, but steamed; that is, the jug of milk should be stood in a saucepan of boiling water for two or three minutes until hot.

To prevent hard soap, prepared with soda, from crumbling, the bars may be dipped in a mixture of resin soap, beef tallow and wax.

A little camphene dropped between the neck and stopper of a glass bottle will render the latter easily removed if jammed fast.

To make silk which has been wrinkled appear like new, sponge on the surface with a weak solution of gum arabic or white glue, and iron on the wrong side.

A piece of paraffine candle about the size of a nut, dissolved in lard oil at 150 deg. Fah., the mixture applied once a month, will keep boots waterproof.

A strong solution of sulphate of magnesia gives a beautiful quality to whitewash.

Leather can be made hard by saturation in a solution of shellac in alcohol.

Paraffine is the best material for protecting polished steel or iron from rust.

Soap and water is the best material for cleaning jewelry.

Sharpening Files by Acid.

A process of rebiting files by means of acid has been for some time tried and talked of, but no definite information as to the best method was to be obtained till the other day. It appears that the plan has been adopted in the two marine stations of Cherbourg and Lorient, and with complete success.

In the first place, the worn files are well cleaned with potash and hot water; they are then left for five minutes in a solution composed of one part of sulphuric acid and seven parts of water; a quantity of nitric acid equal to the sulphuric is then added to the solution, and as much water also, and the files are left in the solution for about forty minutes longer. They are now ready for use, but if they are to be stored they must be brushed over with a little oil or grease to prevent rusting. The files must not touch each other in the solution, being supported by their tongs only.

In order to obtain the most complete results possible, the proportions of acid should be varied according to the size of the files; for instance, for large files one-sixth acid; for bastard ditto, one-eighth, one-ninth to one-eleventh; and for the finest, one-twelfth to one-thirteenth.

The cost of the operation is from ten to fifteen cents, that is to say, from rather more than a penny to nearly three half-pence, while recutting costs about sixpence; and, as a file sharpened in the acid is, it is said, quite as efficient as one that has been re-cut, the saving is large. Files will often bear the operation twice.—*Iron.*

Kalsomining.

As the season for whitening walls is already arrived, many are enquiring for some approved recipe for a superior article for that purpose. One which has been pronounced very good is as follows: Eight pounds of whitening and one-quarter of a pound of white glue make the right proportions. Soak the glue over night in cold water, and in the morning heat it till perfectly dissolved. Mix the whitening with hot water, stir the two thoroughly together, and have the wash of the consistency of thick cream. Apply warm with a kalsomine brush, brushing it well in and finishing it as you go on. If warm skim milk is used instead of water the glue may be omitted. Before the wash is applied all holes and crevices should be stopped with plaster of paris mixed with water. If it is desirable to tint the walls colors may be procured at any paint shop, and stirred into the kalsomine wash.

Another is given as follows: White glue, one pound; white zinc, ten pounds; Paris white, five pounds; water sufficient. Soak the glue over night in three quarts of water, then add as much water again, and heat on a water bath till the glue is dissolved. In another pail put the two powders, and pour on hot water, stirring all the time, until the liquid appears like thick milk. Mingle the two liquids together, stir thoroughly, and apply to the wall with a whitewash brush.

TO REMOVE DENTS.—A novel way to remove dents from brass kettles is given by a lady in the *Household*. Set the bruise on soft snow, and with a hammer pound gently on it until the part recovers its proper shape. Some patience is required to remove bad bruises. Won't loose sand answer as well as snow?

DOMESTIC ECONOMY.

Facts About Flour.

The *Boston Journal of Chemistry*, in a well-considered article on the effects of fine flour, says,

At the present time it is the practice to a large extent among millers, to grind the finest, soundest wheat into fine flour, and the poorest into what is called "Graham flour." This term, "Graham flour" ought no longer to be used. It is a kind of general name given to mixtures of bran and spoiled flour, to a large extent unfit for human food. What we need is good, sweet wheat flour, finely ground, and scarcely put up for family use.

This article we do not find in the market, and the Western miller who will give his earnest attention to furnishing such flour will realize a fortune speedily. The brown loaf made from whole wheat is to our eye as handsome as the white. It can be made with all the excellencies of the white so far as lightness is concerned, and it is sweeter and more palatable. With this loaf we secure all this important nutritive principles which the Creator, for wise reasons, has stored in wheat.

[The statement with regard to the "Graham flour" manufactured at the East does not hold good with regard to that product here.—*Ens. Press.*]

NUTS AND CHEESE promote digestion as a general rule; the conditions being that the nuts should be ripe and the cheese old, both to be eaten at the close of dinner; the digestive agent in both is a peculiar oil which has the property of acting chemically on what has been eaten, and thus preparing it for being the more easily appropriated to the purpose of nutrition. Many think that the more solid portions of the nut should not be swallowed. This is an error; those particles of solid matter are not digested, it is true but they are passed through the system unchanged and act as mechanical stimulant to the action of the internal organs, as white mustard seed swallowed whole are known to do, thus preventing that constipated condition of the system which is so invariably productive of numerous bodily discomforts and dangerous and even fatal forms of disease.

COOKING "GREENS."—Every housewife thinks she can cook "greens." It is the simplest of all dishes; and yet, in most cases, they are not well served, for much depends on the manner in which they are boiled. The water should be soft, and a tablespoonful of salt added to a large sized pot of it, which should be boiling hot when the greens are thrown in; and then it should be kept on the boiling gallop, but uncovered, until they are done, which can be told by their sinking to the bottom of the pot, and they should be skimmed out as quickly as possible into a colander, so that all the water will run out. Press them with a small plate, then turn upon a platter, add a large piece of butter, and cut up fine. Serve while smoking hot.—*London Garden.*

A NEW DELICACY FOR THE TABLE.—The French have recently devised a new delicacy for the table, which is quite as expensive as truffles or *pâté de foie gras*. It is called "bechamel." In its pure state, looks like frozen lard. It is a jelly made from small fowls; they are simmered over a slow fire until cooked to a semi-liquid condition, the bones are carefully removed, and then to two parts of the material five parts of cream are added, and plenty of mushrooms and champagne to flavor it. It takes a great many small fowls, say twenty or more, to make a single pound of this preparation.

CARROTS FOR EGGS.—It is not generally known that boiled carrots, when properly prepared, form an excellent substitute for eggs in puddings. They must, for this purpose, be boiled and mashed, and passed through a coarse cloth or hair sieve strainer. The pulp is then introduced among the other ingredients of the pudding, to the total omission of eggs. A pudding made up in this way is much lighter than when eggs are used, and is much more palatable. On the principle of economy, this fact is worthy of the prudent housewife's attention.

RABBIT CUTLETS.—Prepare the rabbits as you would for a stew; cut the different limbs into the size of cutlets—such as the shoulders cut in half, also the legs, with the ends of the bones chopped off, and pieces of the back, even to the half of the head. Have ready some bread-crumbs and the yolk of an egg beaten up. Drop each cutlet into the egg and then cover it up with bread-crumbs, as for veal cutlets. Fry them a nice brown, and when you dish them pour round them some rich brown gravy, which may be flavored with tomato sauce if approved, and put round them rolls of fried bacon.

LEMON PUFFS.—One quart of milk, the yolks of six eggs, two cups of white sugar, two tablespoonfuls of flour, three lemons. Beat the eggs, sugar and flour together well; beat the eggs first, then add the lemon juice; have your dish lined with paste; do not add the milk until you are ready to put it into the oven. Beat up the whites, add fine white sugar, a large teaspoonful, and beat very light; flavor to taste. When the custard is done spread the icing over it, set it back in the oven and let it brown nicely. Eat as soon as cold.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—An Improved Dry Ore Concentrator; Improved Cork-Soled Boots; Air Sifters; Work at the Foundries, 313. Report of Progress in Suto Tunnel; Chinese Coal and Iron; Land Decisions and Mine Patents; Hints on the Washoe Process; Coal—Relative Value of the Different Kinds Used on the Pacific Coast; Notices of Recent Patents, 320. Short Lectures on Patents; Scenery in Colorado, 321. Patents and Inventions, 324.

ILLUSTRATIONS.—Vincent's Dry Ore Concentrator; Brooks' Cork-Soled Boots, 313. The Mountain of the Holy Cross, 321.

CORRESPONDENCE.—Geological Formations—Quezizite, 314.

MECHANICAL PROGRESS.—Apparatus for the Fusion of Platinum; Magnetization of Steel; American Line of European Steamers; Interesting Incident in the History of Nail Manufacture; American Bessemer Improvements in England; A New Belting Material; The Sand-Belt; Flat and Round Belts, 315.

SCIENTIFIC PROGRESS.—Development of Magnetism in the Rails of Railways; Excrementitious Matter as Fuel; The Ages of Darkness; New Imitation Silver Ornaments; Purification of the More Easily Fusible Metals by Filtration; Sulphur as a Fire Extinguisher; A Simple Glycerine Thermometer; New Process of Gilding on Glass; Nitro-Glycerine, 315.

MINING SUMMARY from the various counties in California, Nevada and Idaho, 316-17.

USEFUL INFORMATION.—How Hot Iron may be Handled; Saving in Wealth; Useful Hints; Suppressing Fires by Acid; Kalsomining; To Remove Dent, 319.

GOOD HEALTH.—Taking Cold; The Lesser Evil; Self-Indulgence; Chlorine Gas in a New Relation; Domestic Remedy for Nightmares; Remedies for Domes, 319.

DOMESTIC ECONOMY.—Facts about Flour; Cooking "Greens;" A New Delicacy for the Table; Carrots for Eggs; Rabbit Outlets; Lemon Puffs, 319.

ENGINEERING.—The Removal of Noonday Rock, 321.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 324.

MISCELLANEOUS.—Timber for the Centennial; On the Assay of Sugar; Cape Cod Ship Canal; Sierra County Mines; Fireless Locomotives, 314. A Great Hydraulic Claim; Small Steam Engines; Building a House in Eight Hours; Tunnel Under St. Bernard; Ancient Saws; Important Engineering Work; Boleo Basin; Extravagance in Buildings; Care of a Grindstone, 318.

Report of Progress in Suto Tunnel.

The following report of progress made in the Suto tunnel, Nevada, for the week ending May 8th, was furnished us by Pelham W. Ames, secretary of the company:

Number of feet in tunnel, May 1, 9,271

Number of feet driven during week, 71

Distance in, May 7, 9,342

ROCK.—A conglomerate, greenstone base, with angular pieces of trachyte imbedded, so hard and tough as to require repeated charges in some holes before blast would take effect. At the last moment the rock is reported as presenting a more favorable appearance.

WORK DONE.—Holes drilled, 372; holes blasted, 405; aggregate depth, 2,303 feet; average depth, 6 7/32; powder consumed, 1,099 lbs.; explosives consumed, 506.

WATER.—The water which had been running in at the face through an open fissure, was left behind on 3d inst., when the fissure took a sudden turn to the south. On the 2d inst., 30 inches of water, (a new body), were struck, making flow from tunnel 87 inches, but this has since decreased to 71 inches. This is now utilized for cutting a wagon road through a high, sandy bluff, near Carson river.

Temperature of air at heading, 79°; shaft No. 1, east, 76°; west, 70°; shaft No. 2, east, 78°; west, 80°; month, 63°. Temperature of water at heading, 79°; shaft No. 1, east, 77°; shaft No. 2, east, 79°; month, 75°.

Currents of air pass in at mouth and down shaft No. 1, up shaft No. 2.

An Arizona mining company has been organized in Virginia City, to prospect in Arizona for precious metals. An expedition will soon be fitted out under Louie Le Page; twenty-five men will compose the party.

Chinese Coal and Iron.

From present indications it appears as if the reports about the Chinese coal fields will amount to a great deal more than reports after all. We see by the English papers that Mr. Henderson, who has passed thirty years in China, and who is now in England, has been commissioned by the mandarin in charge of the arsenals at Tien-tsin and Shenghai, in pursuance of instructions from the superintendent of the Northern Treaty Ports to procure the necessary plant for working the collieries and iron mines, and for smelting and manufacturing iron in that province according to the most approved European methods. He has also been authorized to obtain the services of competent Europeans to direct the works.

This is quite a step in advance for China and one which will be also beneficial to the Pacific coast. The coal area of China is estimated at 400,000 square miles. In one of the provinces there are beds of 30,000 square miles from twelve to thirty feet thick. Every kind of coal is said to be found, hard and soft, bituminous and anthracite. Millions of tons are gathered by surface mining, but none by scientific, deep mining. Steam coal, quite equal in quality to the best South Wales coal, is said to abound at Chaitang, about forty miles from Peking.

There is not at present a single coal mine in China worked on scientific principles. There is neither steam, engine or pump; and the smelting of iron is carried on in the most primitive manner. Owing to the high prices which the Chinese have to pay for foreign coal and pig iron—for the latter sometimes as high as \$50 per ton, the authorities have determined to utilize some of their coal fields and deposits of iron ore, and work them in a systematic manner. The field which has been selected for beginning operations upon, in the southern part of the province of Chihli is easy of access and rich in coal, iron and limestone. These mines are about twenty-five miles from some small rivers, and to complete the chain of communication, a short railway is to be built. The proposition is in the first place to supply the necessities of the national arsenals, but as soon as convenient manufactured iron of all kinds will be produced.

The unexpected and rapid progress of the Japanese has given us some foreboding of what might be expected from their neighbors. Coal or iron in abundance in a place like China places her in an enviable position. The country is filled with men of ingenious minds and skillful hands, and as soon as proper instructors are procured there is no doubt that the Chinese will aim to do more than supply their own internal demands. The idea of China ever becoming a great manufacturing country has never been dreamed of, but there is now a likelihood that it will be so.

For California, the development of the Chinese coal fields is an important thing. Ships bring coal to us from Cardiff and Liverpool, a long and dangerous journey of 20,000 miles, and here are the vast virgin fields of China only about 6,000 miles away. At the prices we pay in San Francisco for good coal, a few dollars per ton would make the greatest difference to our manufacturing interests, and it is sincerely to be hoped that the Chinese coal and iron fields will turn out as well as expected.

Land Decisions and Mine Patents.

Among the decisions recently rendered by the Secretary of the Interior of interest to miners, is the following: Questions of fact and extent of conflict between two mineral lodes cannot be decided by the Department, but must be left to the Courts; therefore, in all cases, where a mining patent is issued for a claim, A, conflicting with another claim, B, previously patented, the "excepting clause" in the last issued patent will read as follows:

"Excepting from this conveyance surface ground conveyed to said B company by its patent, dated —, and also excepting from this conveyance so much of the B lode, if any there be, as was legally conveyed to the said B company by its aforesaid patent."

Secretary Dalano has affirmed the decision of the Commissioner of the Land Office in the case of Hodgdon & Wheeler, against the State of California, holding that when the sixth and thirty-sixth sections are coal lands such sections do not pass to the State of California, by virtue of the Act of March 3, 1873.

The following mining patents have recently been issued. California—El Dorado county, —Henry Hagar and J. H. Straten, German quartz mine. W. J. Hale, Bg Sandy quartz mine. John Blair et al., Bobby Burns quartz mine. Placer county—Charles D. Dewey, Hancock & Watson quartz mine. John W. Eckley, Greene Walter quartz mine. J. H. and R. Hoakin, Hoskin Brothers' canon, placer. Sonoma county—J. A. Robinson, et al., Eaganie quicksilver mine. San Bernardino county—J. A. Robinson, Cynthia gold mine, Amador county—R. C. Downa, et al., Pioneer gravel mine. H. Trneb and J. B. Belliard, placer. Nevada county—H. B. Tichenor, et al., Canon Creek quartz mine. J. M. English, J. M. English quartz mine. Shasta county—Charles Camden and Joseph Chitwood, placer. Del Norte county—Alta California S. M. G. company, Alta copper mine. Nevada—Storey county—Bullion mining company, Bullwhacker lode. Lander county—H. Heyne-

menn, El Dorado lode. White Pine county—John Shoenbar, Rescue lode. Oregon—Josephine county—H. Carron and J. Harrington, pleaser. Jackson county—Georgia Gunders, Enos A. Wall, et al., Queen of the Hills mine. Salt Lake county—Joseph Merion, Rough and Ready mine, two locations.

Hints on the Washoe Process.

To the last report of the United States Commissioner of Mining Statistics, Mr. J. M. Adams, mining engineer of Silver City, Idaho, contributes a valuable paper under the above title, which is valuable to all mill men. Mr. Adams has had great success in the management of the Washoe process, chiefly due, the Commissioner states, to great skill and care in the management of mechanical details and the constant and minute supervision of details. Some of the points he gives are those too often overlooked by mill men, so that the paper will be found practically valuable to a large and intelligent class of metallurgical engineers. The article is the result of seven years' experience in working ores containing silver and gold by amalgamation in pans without roasting, commonly called the Washoe process, in several mills of which Mr. Adams has had charge, but principally in the Owyhee mill, at Silver City, Idaho, which had twenty 650-pound stamps and sixteen pans. He discusses merely the mechanical details of working ores generally, subdividing the subject as follows: 1, preparation of ore for the stamps; 2, crushing in the battery; 3, settling of sand or pulp in vats or tanks; 4, treatment in the pans; 5, results obtained in settlers, agitators and concentrators; 6, straining the quicksilver, clearing of amalgam and retorting; 7, saving of slimes and their subsequent treatment; 8, loss of quicksilver. This article is written for those who understand the arrangement of ore breakers, stamps, tanks, pans, settlers, etc., so there are no detailed descriptions of machinery, no discussions of chemical reactions, and few explanations of fundamental principles. It is assumed that the general arrangement of the quartz mill is understood; and the question will be treated how to secure from such a mill the greatest economy in working, combined with the largest results. Mr. Adams introduces his subject, however, by a single preliminary suggestion, namely that there should be double floors throughout the mill, so that nothing can sift through and be lost. We commence in this number of the Press the first part of Mr. Adams' paper, which is on the

Preparation of Ore for the Stamps.

The more uniform in size the ore is prepared for the stamps, the more evenly can it be fed into the mortars. The ore should be so fine that a single blow of the stamp will be sufficient to shatter thoroughly each piece of ore. If a large piece is fed into the mortar, it may not be broken up until after several blows or drops of the stamp. Besides a large piece raises the stamp and reduces by so much the fall, thereby taking away part of the effect, and consequently diminishing the production. In preparing ore for the stamps, in my first experience at the Owyhee mill, I used merely rock-hammers. The stamps were dropping sixty times a minute, and were given 8 1/2 inch average drop, running without re-setting till the average drop was 10 inches. Breaking by hand on average, hard ore, we could not work over 28 tons a day. Then, by breaking very small by hand, we increased our production to 30 tons a day. But afterward, by erecting a Blake's crusher, the production of the same stamps was raised to 33 tons a day; by breaking the ore very fine we increased it to 37 tons a day on the same ore; and finally by accelerating the rate of running the battery to 93 and 95 drops a minute, keeping the same height of drop, but using a coarser screen, we were able to increase our production to 45 and 48 tons of ore crushed in 24 hours. But in breaking the ore very fine we found that the lowest end of the die, or fixed breaking surface in the crusher, wore away much faster than the middle or upper part; but the middle part was wasted and lost to us except as old iron. We overcame this by adding to the pattern of the die a projection on the lowest end, thus increasing the thickness at this place, and in this way we were able to get full wear of the whole die. The most economical method of preparatory crushing would be to have two breakers, one set above the other. The mill having, as every mill should have if practicable, plenty of natural fall—in other words, being built on the side of a steep hill—the first breaker should be placed above, and set so as to crush to a diameter of two inches. Of course, a long, flat, and thin piece might go through, but at least one dimension will not be over two inches in diameter. The fine, as well as the coarse ore should pass through this breaker. When the ore is dry, let a very small jet of water flow into the mouth of the breaker, to prevent the dust from flying. This dust involves a loss and also injures the machinery. From the first crusher let the ore pass by chute into the second. This should be set so that the breaking surfaces almost meet at the lower end. From here, chutes should lead to each battery of ten stamps or two mortars. If the ore contains much clay, it may be necessary to separate from the massive pieces the fine ore and clay, and deliver the two later to the battery floor without sending them through the rock-breakers, which the clay tends to choke up. The consumption of iron per ton of ore prepared in this way, by double breaking for the stamps, will be about 0.3 of a pound.

Coal—Relative Value of the Different Kinds Used on the Pacific Coast.

We give below the results of experiments with different kinds of coal at the pumping works of the Spring Valley water works of this city. These figures were furnished to the Mechanics' Institute by Charles Elliott, City Superintendent of the Spring Valley water works. There were four tubular boilers, two used at a time, fifty-two inches in diameter by fifteen feet long; sixty-seven three-inch tubes, steam drum four feet high, three feet in diameter; grate bars five feet by four feet, worked with twenty pounds of steam. Two condensing engines, one worked at a time, out-off at nine inches and ten inches, variable out-off regulated by speed of engine; cylinders, four-foot stroke, forty inches in diameter. Four pumps, double acting, geared from engine to make one stroke to 4 368-1000 of engine. All the pumps are run together. Two pumps, fourteen inches in diameter, seven feet stroke; two pumps, twelve inches in diameter, five feet stroke. Speed of engine, 1,900 to 2,000 revolutions per hour, running continuously.

In these estimates there is no allowance made for ashes or for waste of coal in any way. All the coal was weighed accurately, and all the water measured through a Worthington meter. The smoke stack is 116 feet high above the grate bars, square, five feet in diameter at the bottom and seven feet at the top; natural draft. Duty is given for each 100 pounds of coal in foot pounds—that is, pounds raised one foot high with each 100 pounds of coal.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Foreign and American Patent Agency, the following are worthy of mention:

OVERFLOW AND SEPARATING ATTACHMENT FOR GRAIN CLEANERS.—Michael O'Brien, 113 and 115 Mission street, San Francisco. This patent relates to an attachment for grain cleaning devices and a novel mode of employing the same, by which the inventor is enabled to skim off or separate all the coats, barley and lighter impurities from a large body of wheat, so that in place of running the whole quantity through the cleaners, he separates the great bulk of clean grain from a very small proportion of wheat and all the foreign substances, and only the latter will have to run through the ordinary cleaners. By this means the capacity of these cleaners can be reduced to about one-sixth of that now needed. By the means employed, instead of passing all the wheat through cleaning machines and separating it from foreign substances, which would necessitate the use of a number of machines in a mill of ordinary capacity, the great bulk of the wheat can be separated in a clean state, and so small a residue is left to be cleaned in the ordinary manner, that as much can be done with one machine as with six in the old way.

TUCK MARKER.—George Vincent, Stockton, San Joaquin county, Cal. This invention is an improved tuck marker, to be used as an attachment to sewing machines. It consists in the use of a novel creaser or marker, by which the inventor is enabled to use a single edge or point, this being attached to an adjusting bar by which the marker can be moved sideways, or it may be elevated and depressed at pleasure for a heavy or light mark. The marker is operated by the needle bar, but is independent of it, so that by the adjusting device, a long or short stroke can be given at pleasure. The plate of the marker is sored to the presser foot, the cloth plate, or the stationary bar as may be desired, and the marker is elevated after each stroke by means of a spring, and independent of the movement of the needle bar. A gauge or presser extends to one side of the plate, and the ordinary gauge on the cloth plate is set up to it, so that when the work passes beneath this presser, it will be held exactly to its place, against the regular gauge, thus making the tucks absolutely straight.

MINER'S MICROSCOPE.—A photograph of the miner's microscope recently described in the Press will be sent to those desiring it on application to Henry G. Hanke, of this city. Any one can then see exactly what this microscope looks like, the photograph giving the details clearly.

Short Lectures on Patents.

No. 4.—By Jno. L. Boone, of Dewey & Co's MINING AND SCIENTIFIC PRESS Patent Agency.

The Patent.

The granting of a patent is the consummation of a contract between the Government and the inventor. The Government contracts that in consideration of the publication of the invention, so that the public may have the knowledge and benefits of it after the expiration of seventeen years from the date of its publication, it will give the inventor the exclusive right to make, use and sell the same during the said period of seventeen years. The provisions upon which this contract is based, are—first, that the invention shall be new; secondly—that it shall not have been in public use over two years; and thirdly—that the inventor shall fully and clearly explain the invention sought to be protected, and describe the best means of carrying it into effect. In default of either of these conditions the patent will fail, and be voidable. It lies with the inventor to fulfill these conditions, and if he fails he suffers the consequences. A patent, therefore, is a grant or deed based upon certain conditions. The fact that the patent office grants and issues a patent is no evidence that it is a good and valid one. The Government keeps a corps of examiners at work in the patent office, whose duty it is to see that the conditions are fulfilled, as far as possible. This they do by examining each case as it is presented, for the purpose of detecting, if possible, whether any reason can be found to exist for not issuing a patent. If they discover none, the patent is issued, but its validity can be tested at any time in the United States courts, and if upon proof it be found that the patent was wrongfully issued, it is pronounced void and of no effect. A patent is a species of personal property, known in law as an "incorporeal hereditament," that is, it has no body, no tangible form, but is simply a right out of which profits may arise by manipulating it. The manufactured patented article, however, is a "corporeal hereditament," because it can be seen and handled, and has an actual and palpable existence. A patent cannot be seized and sold on execution to satisfy a judgment against the patentee or owner. Being a grant from the Government, the title to it cannot pass from him without his signature, and the document conveying this interest must be recorded in the patent office. A sheriff's signature to an assignment, or any other officer's signature for that matter, would not convey the patent or any interest in it to another party. There is one case, however, in which the law will compel an inventor or the owner of a patent to transfer it to other parties, and that is in case he passes through bankruptcy, either willingly or unwillingly. A bankrupt is supposed to act of his own free will and accord and for his own benefit, even if he should be involuntarily adjudged to be a bankrupt, and the condition imposed upon him in order to allow him to free himself from debt, is that he assign over to his creditors all of his property, both real and personal, which is exempt from execution. His patent, therefore, being considered personal property, and his act being considered voluntary and of his own free will, becomes a part of the estate to be assigned. This is both right and just; otherwise a person who intended to take advantage of the bankrupt law could invest large sums of money in valuable patents, and thus defraud his creditors.

A patent can be bought and sold the same as any other property, either as a whole or in undivided interests, as will be hereinafter more fully explained under the head of assignment.

A patent consists of a deed signed by the Commissioner of Patents and countersigned by the Secretary of the Interior. To it is attached a copy of the specification and claims as prepared and presented by the inventor or his agent, and a copy, or *fac simile* of the drawing which accompanies the application. Previous to 1861, all patents were executed on parchment, 15x20 inches in size. The patents were printed as blank and filled out by hand. The specifications and claims were copied in manuscript on sheets of parchment, and the drawings were made by hand on tracing linen. After March, 1861, the size of patents was reduced to 10x15 inches, and the specifications and claims were printed instead of being copied by hand, but linen tracings of the drawings were still used. In July, 1869, the photo-lithographic process for printing the drawings began to be used and the linen tracing was done away with. The size of the patent was then still further reduced to 8x13 inches, making it at once much more neat and convenient than either of the old styles.

Two independent inventions cannot be covered by one patent, but if two inventions are in any way connected together so that one is necessary to the operation of the other, then they can both be claimed in one patent.

"An American patent expires simultaneously with a foreign patent previously obtained for the same invention, although the American patent was first applied for." (Come. Dec. 1869.) This is for the purpose of giving to the American public the free use of the invention as soon as it becomes free abroad; and thus places our manufacturers on an equal footing

with foreign manufacturers. A patent cannot now be extended after it expires, unless it be by a special act of congress. Previous to March, 1861, all patents were issued for a term of fourteen years, with the privilege of an extension of seven years more at the end of that time, provided the patentee could show that he had not received a sufficient remuneration, considering the value of the invention to the public, but since that date, all patents are granted for seventeen years, and no extension is provided for. The present term is ample. It gives the inventor sufficient time to thoroughly exploit it, and at the same time it does not lay too heavy a burden on the public. A patent dates from the day it is issued, and not from the time the application is made or granted.

If an inventor loses his patent paper, he cannot obtain a new one. He can, however, obtain a certified copy of his patent from the Patent Office, and this certified copy will have all the effect of an original patent and will be recognized in the same manner by the United States Courts.

If an inventor dies before making applica-

THE MOUNTAIN OF THE HOLY CROSS.

tion for a patent on an invention which he has completed, his administrator can proceed with the application in the name of the deceased, and the patent will be issued for the benefit of the heirs.

Joint owners in a patent are not partners. One owner can make use of and sell the patented articles and sell as many rights to others to make use of and sell them as he pleases, entirely independent of the other owners, but he cannot sell any greater interest in the patent than he owns. Any undivided interest in a patent, even a one-hundredth, is a manufacturing interest, and the person who owns such an interest, has as much right to make use and sell the patented articles or machines as the person who owns the remaining ninety-nine one-hundredths. Neither does he have to account to the other owner for any proportion of the profits. A co-partnership agreement, however, can be entered into by the joint owners of a patent so as to combine the interests and make the profit mutual.

At the Belcher mine raising up on the air shaft from the 1,100-foot level is making steady and favorable progress. Work has again been resumed on the upper levels, which have been abandoned since the destruction of the air shaft. The air is again becoming excellent throughout the entire mine.

Scenery in Colorado.

Very few people were aware before the publication of this report on the Geographical and Geological Survey of Colorado, by Hayden, of the beauty of the natural scenery in so many places in Colorado. These reports are so well written, and the localities all described with so much detail, and with such excellent engravings, that it is almost as good as a trip to the country, to read the reports. A most wonderful region is described from Elk Mountain to Middle Park. The trip down Eagle river was made principally for the discovery of some way of access to the mountain of the Holy Cross. The party were obliged to descend the river about two miles, and then climb the steep mountain side over a network of fallen timber. The obstructions to travel were very great; they often labored for a day or two to find some path to approach the mountain peak, and were obliged to cut their way through the fallen timber, and finally succeeded in getting within

about five miles of the base of the peak. The main mass of the peak, like the whole of the Sawatch Range, is composed of granite gneiss. The summit of the Holy Cross is covered with fragments of banded gneiss. The amphibolites on all sides have been gradually excavated, and the more or less vertical sides show the intermediate steps very clearly.

The characteristic feature of the Mount of the Holy Cross, as shown in the engraving, is the vertical face, nearly 3,000 feet on the side, with a crose of snow, which may be seen at a distance of fifty or eighty miles, from other mountain peaks. This is formed by a vertical fissure about 1,500 feet high, with a sort of horizontal steps, produced by the breaking down of the side of the mountain, on which the snow is lodged and remains more or less all the year. Late in the summer the crevices are very much diminished in size by the melting of the snow which has accumulated in the fissures. A beautiful green lake lies at the base of the peak, almost up to the timber line, which forms a reservoir for the waters from the melting snow of the high peaks. From this, one of the main branches of the Roaches Moutonnes creek flows down the mountain side, forming several charming cascades in its way. The worn out rocks or "sheep-backs," in the valley of the creek, display most remarkable examples of the curious workings on the surface of the gneiss produced by the separation of the different constituents of the rocks.

ENGINEERING.

The Removal of Noonday Rock.

The U. S. Engineers stationed in this city have their hands pretty full this year with engineering work of interest to the general public, as well as the usual routine work on fortifications, etc. Among them may be mentioned the improvement of the Sacramento river, Oakland harbor improvement, San Diego harbor improvement, removal of Rincon rock in San Francisco bay, and removal of Noonday rock, outside the entrance to this port.

This latter piece of work was accomplished on the 7th inst., by Mr. Edward Moore, of Portland, Maine, the contractor. Noonday rock is in the open sea, about three nautical miles to the northward and westward from the North Farallone, and about thirty-three miles to the southward of west from Fort Point, in the open ocean. Directly over the rock at mean low water, there were twenty-one feet of water, although the water close around it, according to the U. S. Coast Survey, is from twenty to thirty fathoms deep. The rock was in the form of an irregular dome with steep sides. The extreme dimensions at different depths below the plane of mean low water, were, before the blast, as follows: At twenty-one feet (the top) five feet three inches by three feet six inches; at forty-one feet, twenty-three feet eight inches by eleven feet eight inches; at forty-seven feet, twenty-six feet ten inches by twenty feet eight inches. From this it will be seen that the contents above the depth of forty-one feet were about 125 yards, and that the cubic contents above the depth of forty-seven feet were about 200 yards.

The contract for blowing up the rock was taken by Mr. Moore, for the sum of \$20,000, and he came on from the East, bringing with him his own divers and foremen. Considerable delay was occasioned by a series of accidents to the machinery of the steamer *Fideler* which was employed in the work, and by the fact that three different times the booms, rope and all were stolen by coasters, necessitating delay in again finding the rock. About sixteen different trips were made to the rock before the work was accomplished, most of them, however, from San Francisco bay, where the *Fideler* anchored at night.

When it is remembered that the rock lay out in the open Pacific, on a very windy and rough part of the coast, where there is always a heavy swell, the difficulty of the task will be understood. The contractor at first intended to place his nitro-glycerine on the side of the rock, trusting to the weight of water for tamping. Noticing, however, that most of the large rocks on the coast have in them natural cavities and sometimes arches, he thought there might probably be one in Noonday. On examination the divers found a cavity at a depth of fifty feet from the surface, which exactly suited the purpose.

As it was at such a depth below the surface, and in such an advantageous position, 800 instead of 3,000 pounds of nitro-glycerine were used, being fired by electricity from a boat about 600 feet distant, the steamer lying about half a mile away. In conversation with Mr. Moore, he stated to the writer that the eight was a most magnificent one. When the explosion occurred a solid body of water in the shape of a cone went up into the air about 600 feet, the spray and debris going up about 1,000 feet. One very large piece of the rock, apparently weighing about 150 tons, was thrown up at least 500 feet, striking the water with immense force and noise. The explosion calmed the sea down within a radius of half a mile, it being covered with sea weed, sponge, etc., and thousands of fish. Several seals were killed, as were several tons of fish. A hasty examination after the blast showed nine fathoms of water on top of the rock, although only eight fathoms were called for. An official examination has been made by Lieut. John H. Weeden, of the Corps of Engineers, and a report made on the result of the blast. This work was done under the direction of Lieut. Col. C. Seaforth Stewart, of the Board of Engineers of the Pacific coast. This formidable obstruction to navigation has been successfully removed, but unfortunately there are many others in the same locality some of which are perhaps more dangerous than Noonday, and being larger, much more difficult and expensive to remove.

The yield of bullion of the Consolidated Virginia mine for this month will not be quite so great as last, owing to the shutting down of the Occidental mill for repairs. However, the yield will amount to something over \$1,500,000. The ore stops on all of the ore-producing levels are not only holding out finely, but promise a rich yield for months to come. The mine is now yielding the extraordinary amount of 560 tons of ore, the milling value of which is about \$100 per ton. A few dozen mines like this belonging to the community might pay the national debt in a little while.

At the Utah mine, Washoe, a large force of men are constantly employed laying the heavy stone foundations, and in getting the mill timbers, the pumping machinery and engines ready to place in position at the very earliest moment possible.

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household. It is unequalled for cleansing Woolen Fabrics, Outlets, Carpets or Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing. It renders water soft, and imparts a delightful sense of coolness after washing. DIRECTIONS.—For Laundry, use two to four table-spoonsful to a wash tub of water. For bathing, use one table-spoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterward. For stimulating the growth of plants, use a few drops in every pint of water used in watering. PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents. Also, SULPHATE OF AMMONIA for chemical purposes, fertilizing, and the preparation of artificial manures. AMMONIACAL PREPARATION, for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing and PURE LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes.

E. V. HAUGHWOUT & CO.,
26 Beekman Street, New York.Ayer's Sarsaparilla,
FOR PURIFYING THE BLOOD.

This compound of the vegetable alteratives, Sarsaparilla, Dock, Stillingia and Mandrake with the Iodides of Potassium and Iron makes a most effectual cure of a series of complaints which are very prevalent and afflicting. It purifies the blood, purges out the

lurking humors in the system, that undermine health and settle into troublesome disorders. Eruptions of the skin are the appearance on the surface of humors that should be expelled from the blood. Internal derangements are the determination of these same humors to some internal organ, or organs, whose action they derange, and whose substance they disease and destroy. AYER'S SARSAPARILLA expels these humors from the blood. When they are gone, the disorders they produce disappear, such as Ulcerations of the Liver, Stomach, Kidneys, Lungs, Eruptions and Eruptive Diseases of the Skin, St. Anthony's Fire, Rose or Erysipelas, Pimples, Pustules, Blisters, Boils, Tumors, Tetter and Salt Rheum, Scald Head, Ringworm, Ulcers and Sores, Rheumatism, Neuralgia, Pain in the Bones, Side and Head, Female Weakness, Sterility, Leucorrhoea arising from internal ulceration and uterine disease, Dropsy, Dyspepsia, Emaciation and General Debility. With their departure health returns.

JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merit. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Millmen are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

THE PACIFIC COAST
12 Per Cent.
CONSOLS.

Interest Payable Monthly, in Gold and Silver.

A MINING, REAL ESTATE AND LAND
COMPANY.

Incorporated February 12th, 1875.

Capital Stock, --- \$27,000,000,

IN CONSOL SHARES OF \$1 EACH,

Of which 13,500,000 shares constitute the Sinking and Investment Fund. Interest payable monthly at the rate of 12 per cent. per annum. Certificates of CONSOLS share receivable at their par value in exchange for any Mining, Real Estate or Landed Property of the Company.

Directors:

T. PHELPS, **W. S. REYNOLDS,**
B. M. FETTER, **L. K. GOODMAN,**
J. H. BATES.

Certificates of CONSOLS only issued at the rate and proportion of 50 per cent. of the cash valuation of property to be represented in CONSOLS shares. Dividend paid from profits and sales of property, and only on shares of CONSOLS that have been issued for property valued and entered on the books of the Company.

Principal Office, 526 Kearny Street.

Principal Depository Agency, Greenbaum's Bank, 306 Montgomery street. After May 1st, office removed to 306 Montgomery street.

Depository Agencies for payment of interest on CONSOLS will be established in the principal cities in the United States and Canada, and in London, as when required.

Interest payable on the 5th of each month at any Depository Agency of the Company.

Certificates of interest-bearing CONSOLS, Class A, First Series, issued for Mining Property in Washoe, Storey and Lyon counties and on the Comstock Lode, in Nevada, will be ready for delivery to subscribers and purchasers on or before April 10th 1875.

Orders for not less than one hundred shares of CONSOLS, with the purchase money required (\$1 per share), may be sent through Wells, Fargo & Co., at our expense. No certificate of stock issued for less than twenty shares. All orders must be addressed, "Office of the CONSOLS M. R. E. and L. Company, 526 Kearny street, San Francisco."

T. PHELPS, President
W. S. REYNOLDS, Secretary.

apr3-sa-bp

This is a Sure Cure for Screw Worm, Scab and Foot Rot in Sheep. It also kills Ticks, Lice, and all Parasites that infest Sheep.

Prevents scratching and greatly improves the quality of the wool. One gallon of the Dip properly diluted with water will be sufficient to dip one hundred sheep, so that the cost of dipping is a mere trifle, and sheep owners will find that they are amply repaid by the improved health of their flocks.

This Dip is guaranteed to cure when used according to directions, and to be vastly superior to Corrosive Sublimates, Sulphur, Tobacco, and other remedies which have heretofore been used by farmers.

Circulars sent, post paid, upon application, giving full directions for its use, also certificates of prominent sheep growers who have used large quantities of the Dip, and pronounce it the most effective and reliable known Cure and Preventive of Scab and other kindred diseases in Sheep.

mrl3-bp

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR APPLICATION—requiring no thinner or dryer, and will not spoil by standing any length of time.

It is Cheaper; more durable, more Elastic, and produces a finish more Beautiful than the best of any other Paint.

It will not Fade, Chalk, Crack, or Peel off, and will last twice as long as any other Paint.

In ordering White, state whether for Outside or Inside use, as we manufacture an Inside White (Flat) for inside use, which will not turn yellow, and produces a finish superior to any other White known.

Put up in 4, 8, 12 and 6 gallon packages, and in Barrels. Sold by the Gallon.

For further information send for Sample Card and Price List, or apply to the office.

OFFICE AND DEPOT: 117 Pine Street, near Front.

3v9-cow-bp-ly

FACTORY: Cor. 4th & Townsend Sts.

SAN FRANCISCO, CAL.

F. MANSELL & CO.,

The Mining Stock Market.

Mining stocks, instead of having recovered from their continued dullness, seem to have got worse. A very marked decline is apparent in nearly all descriptions of stock, as our table shows. Ophir, the great leader of the market has tumbled down to \$65.50, the lowest figure reached since February. Everything else is on the same level, Comstocks and all. The cause of the fall in Ophir last week was that on the 1600-foot level a winze has been sunk to the depth of thirty feet perpendicularly, which, at that depth, with the ledge pitching to the east, naturally cut through the rich ore and passed into the low grade lying next to the west side of the ledge, causing a considerable drop in the price of the stock. This cutting into the poor ore with this winze was nothing more than was expected, and does not in the least affect the intrinsic value of the mine; still, the ways of the stock market are past finding out, and it is difficult to tell why the decline has occurred. The Gold Hill News states that the truth of the matter is that no large and extensive body of rich paying ore has yet been developed in the Ophir mine. Some tolerably wide seams of it, however, are met with, and this one at the 1600-foot level is one of the most promising, but it is not so extensive in any direction that drifts, cross-cuts or winzes cannot run off through it. The dip east allows the winze to run through it into low grade ore next to the west wall.

For dividends this month so far we have the big one of the Consolidated Virginia, of \$1 per share, aggregating \$1,040,000; the dividend of the Empire (Grass Valley) mine of fifty cents per share; the Jefferson (No. 2) of fifty cents per share; and the Manhattan (No. 1) of \$1 per share. How long the present depression in stocks will last of course no one can tell, but it seems to be getting worse and worse.

The Overman new pumping machinery is working very well, the water being drained from the shaft. There is no doubt but that the present powerful machinery will be amply sufficient to not only keep down the water, but to drain any body that may be tapped while prosecuting the work of sinking.

THOUGHTLESSNESS.—Persons sometimes return the paper, marked "stop this paper." Their name being pasted on the sheet they think that is all we need to do to cancel their names off. Now that is thoughtless. Your P. O. address is not such a very common name. We have thousands of names arranged out according to locality. Our mailing clerk does not know where everybody lives.

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in the Mining and Scientific Press and other S. F. Journals.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., May 11, 1875.

FOR WEEK ENDING APRIL 27, 1875.

POTATO DIGGER.—James J. McKeunor, S. F., Cal.

COMBINED BLOTTER, PAPER CUTTER AND RULER.—Frank R. Angell, Los Angeles, Cal.

WAGON-JACK.—Wm. Henry Horn, Santa Cruz, Cal.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

REBROGATED OPTIC M. Co.—May 7. Location: Wathoe, Trustee.—Wm. Sherman, J. F. Nesmith, J. P. Canton, P. Malloy and G. W. Gordon.

ALMADEN CO. M. Co.—May 8. Location: Salinas District, San Luis Obispo county, Cal. Trustees.—John F. Money, Wm. J. Ford, W. G. Jones, J. Dennis, Cullen and Eustace Neale. Capital, \$10,000,000.

BUCKEY WATER & HYDRAULIC M. Co.—May 8. Location: Trinity county, Cal. Trustees.—R. R. Craig, A. L. Warner, W. H. Lowden, J. Craig and S. H. Atkins. Capital, \$1,500,000.

SOUTH CAPITAL M. Co.—May 10. Location: Storey county, Nevada. Trustees.—F. G. Smith, J. W. Moyle, O. M. Peck, W. F. Meyers and E. Wheaton. Capital, \$6,000,000.

NORTH MEXICAN G. & S. M. Co.—May 10. Location: Virginia City, Nevada. Trustees.—O. Denerwald, J. B. Treadwell, Marshall Hubbard, J. P. Moore and H. E. Greene. Capital, \$10,000,000.

CARLISLE G. & S. M. Co.—May 10. Location: Meadow Valley Mining District, Nevada county, Cal. Trustees.—Wm. H. Brockman, Samuel Green, Henry Levy, Jacob Zobel and Chas. H. Dewey. Capital, \$1,000,000.

General News Items.

Vice President Wilson has been traveling through the South and expresses himself so much gratified at the true Union sentiment manifested by the people. He has faith in this future of the whole country. Such utterances as these of the Vice President do a great deal of good.

AND now Stockton wants an Elains sensation. A copy from the original was hung up in a billiard saloon of that city. Last Saturday night it was out from the frame, a la San Francisco, and carried off. A Captain Lees is wanted in Stockton.

WILBUR H. STORAY, proprietor of the Chicago Times, has been convicted of libeling the character of a young lady of Rockford, and \$25,000 is the sum the jury think he ought to pay as a salve to heal her injured reputation.

ANOTHER OCEAN HORROR.—This steamship Schiller was wrecked on the Scilly Islands, English channel, on the 7th inst. Three hundred and forty lives are reported lost and only fifteen are known to have been saved.

DOO fanciers may be interested in learning that the Treasury Department acquiesces in the judicial decision that German sausages are exempt from duty under this special provision for Bologna sausages.

A BANK under the control of Flood & O'Brien is to be started in their new building, corner of Montgomery and Pine streets. The capital of the institution will be \$10,000,000.

LEE AR CHU, convicted of the murder of this boy Axtel in this city, has been sentenced to be hanged on Friday, July 2, between the hours of 12 noon and 3 p. m.

THE American rifle team have accepted the tender of a free passage from the Inman company, and will sail for Ireland on the City of Chester early in June.

A COLLISION occurred between two freight trains on this C. P. R. R. last week, by which a brakeman was killed and a conductor severely injured.

HENRY RHODES & Co., of Victoria, have been awarded the contract for carrying the mails between British Columbia and this city.

A PLANING mill and saw mill on the corner of Fourth and Berry streets were destroyed by fire last Sunday afternoon. Loss, \$50,000.

A DISEASE of the eye has broken out among the Nevada Pines, which threatens to destroy the eyesight of the whole tribe.

A JEWELRY store in Albany was entered by burglars last Sunday afternoon and \$15,000 worth of goods stolen from the safe.

GENERAL Phil Sheridan is to be married to Miss Rucker, daughter of General Rucker of his staff, in June.

OVER \$100,000 worth of dogs, mostly pointers and setters, have been imported from Europe during the past two years.

OLD John Bender, the Kansas murderer, has escaped from the custody of this Arizona officers.

JOHN H. BURKE, a resident of this city, dropped dead in an Oakland car last Sunday.

SENATOR Booth has returned home.

The C & C shaft, for the Consolidated Virginia and California mines, on this Comstock, is down 450 feet, the bottom in fine sinking ground, the rock blasting out finely and no water whatever to interfere. Laying this foundation and making preparation for the erection of the splendid powerful hoisting and pumping machinery, which we recently described, is making rapid progress. One set of the boilers are already in position, and all the men are employed at this work that there is room for.

At the Sierra Nevada mine, on the Comstock, a new and powerful air compressor is being erected, with which to run a set of Burleigh drills at the bottom of this shaft. As soon as finished, these drills will add greatly to the speed of the sinking.

The clipper ship Three Brothers has beaten the British King to Liverpool.

BLEEDING FROM LUNGS, CATARRH, BRONCHITIS, CONSUMPTION. A WONDERFUL CURE.

ROCHESTER, N. Y., Jan. 13th, 1874.

R. V. PIERCE, M. D., Buffalo, N. Y.:

Dear Sir:—I had suffered from Catarrh in an aggravated form for about twelve years and for several years from Bronchial trouble. Tried many doctors and things with no lasting benefit. In May, 1872, becoming nearly worn out with excessive editorial labors on a paper in New York City, I was attacked with Bronchitis in a severe form, suffering almost a total loss of voice. I returned home here, but had been home only two weeks when I was completely prostrated with Hemorrhage from the Lungs, having four severe bleeding spells within two weeks, and first three inside of nine days. In the September following, I improved sufficiently to be able to be about, though in a very feeble state. My Bronchial troubles remained and the Catarrh was tenfold worse than before. Every effort for relief seemed fruitless. I seemed to be losing ground daily. I continued in this feeble state, raising blood almost daily until about the first of March, 1873, when I became so bad as to be entirely confined to the house. A friend suggested your remedies. But I was extremely skeptical that they would do me good, as I had lost all heart in remedies, and began to look upon medicines and doctors with disgust. However, I obtained one of your circulars, and read it carefully, from which I came to the conclusion that you understood your business, at least. I finally obtained a quantity of Dr. Sage's Catarrh Remedy, your Golden Medical Discovery and Pellets, and commenced their vigorous use according to directions. To my surprise, I soon began to improve. The Discovery and Pellets, in a short time, brought out a severe eruption, which continued for several weeks. I felt much better, my appetites improved, and I gained in strength and flesh. In three months every vestige of the Catarrh was gone, the Bronchitis had nearly disappeared, had no cough whatever, and I had entirely ceased to raise blood; and, contrary to the expectation of some of my friends, this cure has remained permanent. I have had no more Hemorrhages from the Lungs, and am entirely free from Catarrh, from which I had suffered so much and so long. The debt of gratitude I owe for the blessing I have received at your hands, knows no bounds. I am thoroughly satisfied, from my experience, that your medicines will master the worst forms of that odious disease Catarrh, as well as Throat and Lung Diseases. I have recommended them to very many, and shall ever speak in their praise. Gratefully yours,

WM. H. SPENCER.

P. O. Box 507, Rochester, N. Y.

THE OTHER SIDE.

TURBINE vs. DEXTER.

TO WHOM IT MAY CONCERN.

Whereas, the "Dexter Windmill Company" (composed of two individuals), have published a statement that the so-called Turbine Windmill is an infringement on the Dexter Windmill, and that said Dexter Windmill Company will prosecute any one who purchases the Turbine, I am called upon in the name of Truth and Justice to contradict their statement. The Turbine is no infringement on the patent held by Dexter Windmill Company. Read what Gov. H. H. Haight says on the subject:

SAN FRANCISCO, Esq.—Dear Sir: From an examination of the patent now held by the Dexter Windmill Company, and your patent dated March 16th, 1875, it seems clear to me that your right to manufacture and sell under your patent is unquestionable, without any license from the Dexter Windmill Company. If there were any room for question it would be disposed of by the fact, which I understood to be conceded, that the novelty of the invention patented to you first and transferred to the Dexter Company, consists in the combination with the Governor, and this is dispensed with in your patent of March 16th, 1875.

Respectfully yours, H. H. HAIGHT. Now, for two months or more I was Superintendent of the Dexter Windmill Company, and owned one-third of the stock of said company. I worked early and late in the interests of the company. I had to perform many duties not properly my own, while the Secretary, who was receiving the same salary as myself, seemed entirely careless about his duties. Finally it was told me by one and another that there was to be an effort made to oust me out of my position. I did not believe the statement, but subsequent events have proved the truth of it. I was ruthlessly thrown from my position, and I asked in vain for an excuse for the act. I was answered with insults. My position and salary were given to the President, who did not devote one-fourth

of the time and attention to the business that I had done.

One officer who was incapacitated by a falling, and whose salary was the same as mine, was retained, and seemed to be the moving spirit in getting me out, and afterward made boast of it. "We went to work systematically to get Southwick out, and we succeeded." Then an assessment of one dollar per share was levied on the stock, as I now believe, for the express purpose of freeing me out, and the stock was bought in by the parties now owning it for the assessment and cost of advertising. I then became discouraged and thought of leaving the State. But I had been writing a convenient time to apply for a patent on some very important improvements which I had made, and several of which the D. W. Co. were using. I then found that the improvements would insure me an opportunity to again engage in the Windmill business in California. I have secured the patent which covers the metal binding or shoe on the end of the shutters, and the pivot by which it is secured to the platform, the overlapping shutter having its inner edge bent for the purpose of regulating the amount of wind admitted to the wheel. This takes the place of the governor in the other patent. Also, the lever above the wheel, pivoted in the center and connected by rods, cranks and gudgeons to the shutter in such a manner as to be easily worked by cord and pulleys to open and close the shutter. These improvements are owned only by the Dexter Windmill Company, which will furnish the mills and guarantee protection to the purchaser. Parties having mills of the Dexter Windmill Company, manufactured after this date, are warned to be sure that said mills are free from said improvements, otherwise they will lay themselves liable to the law.

Any one wishing to see either or both of my patents can have an opportunity by applying to me anywhere, as I carry them always with me.

Respectfully,

A. H. SOUTHWICK.

Patentee Dexter and Turbine Windmills

THE PEOPLE'S COMMON SENSE MEDICAL ADVISER.—This work, edited and published by R. V. Pierce, M. D., of Buffalo, N. Y., has been received. It contains 886 pages, with numerous illustrations. Price, post paid, \$1.50. We shall review it at leisure for information for ourselves and readers.

IMPROVED HOISTING ENGINES.

HOISTING ENGINES.

COOK, RYMER & CO.'S Celebrated Hoisting Engines have been too long
in use on the Pacific Coast to require any special recommendation from us.
We refer with confidence to any one of the hundreds now in use. We simply
state that they still sustain their old reputation, the manufacturers not
having followed the now too common practice of reducing the quality of
material and workmanship for the sake of competing with cheaper engines.
For details of sizes send for price list. We desire to call particular attention
to our new

MINING HOISTING ENGINES.

(Manufactured by the same parties.)

Which have just been introduced on this Coast. The plans and specifications
are the combined efforts of our most successful MINING ENGINEERS, and the
result is the most complete

DOUBLE-DRUM HOISTING ENGINE

Ever built. Their advantages will be seen at a glance by any one familiar with
the necessities of a mine. One of these engines may be seen at work in the
Belcher mine, and one in the Ophir, on the Comstock lode, to both of which
we refer. We have all sizes of these engines constantly on hand. For
sale only at

TREADWELL & CO.'S,

and the Sharpley Engine.

The Mining & Scientific Press.

Started in 1860, is one of the oldest weekly journals now
published in San Francisco. It has been conducted
by its present proprietors for ten years, during which
period it has been repeatedly enlarged and constantly
improved. The active and steadfast efforts of its pub-
lishers have gained for its conduct an amount of practi-
cal experience greater than any other publishers have
accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent ob-
tainable for our special class journal; for engravings,
for interesting news and correspondence, and for print-
ing a large-sized, handsome sheet, is unequalled by that
of any other American weekly west of the Mississippi.

As a PRACTICAL MINING JOURNAL it has no rival on
this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC
journal of the Pacific States.

Miners, Assayers, Millmen, and Metallurgists in the
United States should take it.

Pacific Coast Mechanics, Engineers, Inventors, Manu-
facturers, Professional Men, and Progressive and
Industrial Students should patronize its columns of
fresh and valuable information.

Mining Engineers, Superintendents, Metallurgists, Mine
Owners and Mine Workers throughout the world
should profit by its illustrations and descriptions
of New Machinery, Processes, Discoveries and
Record of Mining Events.

Intelligent thinkers throughout the land, in high or
humble situation, who would avoid literary trash for
genuine information, should SUBSCRIBE AT
ONCE.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Fran-
cisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers
to be superior to any they have ever used; feed con-
stantly by pressure of condensed water, supplied by
pipe A, regulated under the oil by valve J, and forced
out through check valve and pipe B into the steam pipe
C, it then becomes grossly heated, passes to all the
valves and cylinder at every stroke of the engine, glass
tube I indicates amount used per hour. Packing on
rod and stems lasts longer, and this rings on the piston
will not corrode. One pint of oil will last from three
to six days, according to speed and size of engine; I,
sliding gauge, K, valve to shut off when engine stops;
H, F, valves to shut off in case of frost; steam does not
enter this cup, it is always cool; warranted to give satis-
faction. Patented February 14, 1871. Made and sold by
California Brass Works, 125 First street, S. F. 24v23

VOLUME XXX
Number 21.

Rae's System of Amalgamation.

One of our Eastern correspondents, Mr. W. C. Quimby, sends us a description of a matter of interest to many of our readers, which has recently been attracting considerable attention in the Eastern States. It is an electrical process of extracting precious metals from ore. The method is called "Rae's System of Amalgamation." The following extract from an article in the New York Sun contains a correct description of this system and its mode of operation, and the engraving on this and page 337 will show the reader the mechanical arrangements:

This process, which has been used for more than a year in the mill attached to a gold mine, with the most positive success, is the invention of Dr. Julio H. Rae, who for many years made electricity a special study, then rendered himself practically familiar with the methods and principles of gold and silver amalgamation, as used in mining, and finally applied electricity in a way to effect an amalgamation so perfect as to

Save From Eighty to Ninety-Five Per Cent. Of the precious metals contained in the ores, uncombined with refractory salts. That his process does achieve this result is attested by men of science and practical miners, who, incredulous at first, visited the mill where the method was in full operation, applied the severest tests, examined thoroughly the facts, in one case at least, took absolute charge of the mill, to make any deception impossible even were it contemplated. One after another they became fully convinced that the process would actually, did actually, accomplish all that was asserted in its favor by the inventor.

Having watched all the work done in extracting the gold contained in a ton of ore, from the time when the rock was placed in the mortars to be pulverized till the amalgam was ready for the retort, the writer can describe

The Process From Personal Knowledge. In this process no water is introduced in the mortars and the rock to be crushed must be perfectly dry. In all mills the degree of fineness to which the rock is powdered is regulated by a screen, through which alone the pulverized ore finds egress from the mortars.

In Rae's method very fine screens are used, so that the rock is reduced to a very minute powder before it escapes from the batteries. It is then carried by an elevating belt to a platform above the battery, where it is emptied into a car large enough to hold one ton of crushed rock. When this amount is received, the car is removed and another placed in its stead. The car already charged with the ton of powdered rock is rolled forward till it is above the amalgamating machinery. This consists of a large tank, so inclined that fluids will readily flow from it through a vent in the lower end. Across this tank, their axes resting on journals supported by its sides, are two cylinders, each seven feet long and four feet eight inches in diameter. On one side of each cylinder, half way between the ends, is a large opening called a manhole; on the other side, opposite, is a large faucet. By an ingenious contrivance the manhole can be closed with absolute tightness. Inside, upon the axis of each cylinder, is a voltaic pile. Below the vent of the tank is a circular cistern, five feet in diameter and one foot six inches high, called a dolly or agitating tub. An upright shaft, standing on the center of the bottom of this tub, is made slowly to revolve. From a horizontal cross-piece, placed on this shaft a little above the level of the tub, iron teeth one foot six inches long descend. On the side of this tub opposite the vent of the tank are four holes, one above the other, through which fluid may pass into an amalgamated copper vessel, in shape an inverted hollow truncated cone. In the center of this copper vessel, called a washer, is a hollow sphere pierced with small holes. In this sphere terminates a water pipe connected with a reservoir above, and provided with a stopcock to regulate the flow and pressure of the water. Below this washer is another, smaller, but in every other respect similar in shape and arrangement. Such is the amalgamating machinery. The amalgamation is effected as follows:

From the car above the machinery the pulverized ore is, by a chute, emptied into one of the cylinders through the manhole. Water is then introduced till the cylinder is two-thirds full. Any necessary chemicals, and from fifty to 100 pounds of quicksilver, according to the richness of the ore, are added at the same time. The manhole is then closed so tight that nothing can escape, and the cylinder is revolved during from three to four hours. Then the faucet is opened, and ninety to ninety-five per cent of the quicksilver runs into a vessel ready to receive it. Another vessel is substituted for this, and receives a large portion of the amalgam. The remaining contents of the cylinder are then allowed to flow out into the tank and are washed down into the dolly-tub where they are constantly agitated by the teeth on the cross-piece before mentioned. From this tub they pass into the washer, in which the jets of water from the holes in the hollow sphere keep the mass constantly in movement, so that any amalgam quicksilver or gold which shall

equipoise necessary to accept or reject theories or parts of theories, according as they should stand the list of scientific examination, he first proceeded to make himself familiar with all the known facts of amalgamation, then to develop and apply his theory. He frankly admits that many times his attempts to accomplish what he has now achieved seemed to result only in failures. But having assured himself that he was following the lead of a settled principle, he was certain that apparent failures were but so many processes of elimination, and he did not hesitate to invest his time and money in the work of bringing into actual and manifest operation what he was satisfied must be a latent fact.

He appears very positive as to what his system can do, and very careful not to claim for it anything that its actual performances will not warrant. So scrupulous was he in this respect that he refused to sell or permit his system to be used by any one else till he had put it to the practical and satisfactory test of a

Elevation—Perspective View of Complete Mill in Running Order.

have escaped from the cylinder and the dolly-tub sinks to the bottom of the first, or, at any rate, of the second washer.

Before seeing the demonstration of actual experiment, expert miners refused to believe that the efficiency of quicksilver, for the purpose involved, would not be destroyed by the treatment it receives in this process. As a matter of fact, conceded and asserted unanimously, the mercury comes from the cylinders bright, lively, and in the best possible condition to seize the particles of gold.

Instead of the car by which the crushed ore is moved, carrying belts or screws, and a hopper over the cylinder, are sometimes used. This indeed is the most advantageous arrangement, as it saves man power. Our correspondent writes that he has had several interviews with the inventor. He says he is companionable, ready, keen, and seems to be dogmatic, only as to the merits of his invention, which he has proved by long, patient and thoroughly conclusive experiments. Our correspondent says: Years ago, while a practicing physician, his attention was particularly turned to the study of electricity, more especially its medicinal and mechanical effects. In the course of time, the imperfections and waste of the common methods of amalgamation were brought incidentally to his notice. He conceived the theory that by the use of electricity better results could be obtained. A practical man, with the energy, the brains and the mental

year's constant use in a quartz mill. This test was triumphantly sustained. Eminent experts who had come to have a very strong prejudice against every kind of new "process," and were utterly skeptical as to the merits of this system, visited the mill, took charge of it, examined the ore and the tailings, in short applied the severest scrutiny, and came away thoroughly convinced, and to-day this system could have no stronger endorsers than are these very experts. The special merits and advantages claimed for this method are:

1. Preservation of quicksilver from loss, and always in a clear, bright and healthy condition, while its activity is increased.
2. Ease of manipulation.
3. Economy in construction of, and in working the mill.
4. Simplicity of the entire work; no mystery involved; no superior scientific skill required.
5. Close approximation of metal extracted from all milling ore to full value of such ores, as shown by fire assay.
6. Certainty that by the use of this method low grade ores may become valuable, and many mines now abandoned may be rendered profitable.

Another great advantage is that any man of ordinary intelligence may be taught to run this system in a few days, and that the mill will not be stopped to "clean up," as it is done with every ton of ore amalgamated.

It is a well proven fact that mines which

before this method was used were unable to pay working expenses, by its use have been made to yield a good profit. It is alike adapted to the working of high or low grade ores.

What I have said may appear like very positive and high praise, but I believe that facts will show that it is in no respect exaggerated. Dr. Rae will probably be in California some time in June, when he will make a practical demonstration of the working of his process before those interested.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening last, Vice-President Henry Edwards in the chair. Gustave Mahe and Ernest L. Hneher were elected resident members, and Jas. L. King and Pembroke Murray were proposed as candidates. The donations to the museum were as follows:

Collection of tertiary fossils, collected north of San Francisco, from Dr. Henry Hemphill.

Fragmente of wood from an artesian well 180 feet deep, presented by John Hall, Alvarado.

Specimen of Ahies Douglasii, from Mr. Henry Edwards.

Indian mortar, presented by Mr. Amos Bowman.

Mounted peacock (a very handsome specimen), from Mr. James Lick.

Portion of a skull, presented by Mr. M. O'Hara, of Jacksonville, Oregon.

Small and peculiarly colored snake, found by Master Willie Lockington, in the hills back of Oakland.

Mr. Wm. Guerin read an exhaustive paper on the "Sewerage System of San Francisco." Mr. Guerin's idea is to divide the area of the city into three districts, and he described the form, pitch, and several distributory laws applicable. He thought flushing the sewers of little value, but advocated an arrangement of grade so that sewers along streets having a great elevation should be discharged into those having less, and thus the velocity of flow in one system made to contribute to wash out and keep free those necessarily more level. The paper included many minute details, and was mathematically illustrated by drawings upon the blackboard. This was one of the most valuable engineering papers that have been read before the Academy for some time.

An interesting paper by J. E. Clayton, of Salt Lake City, on "The Glacial Period—its Origin and Development," was read. This is referred to elsewhere in this issue.

The Secretary then read an extract from a letter by A. W. Keddle, County Surveyor of Plumas county, confirming the claim of Dr. Harkness as the rightful discoverer of Lake Harkness. It was asserted by some of the papers that this lake was perfectly well known, and that the Doctor was not the discoverer; Mr. Keddle, however, made the official map of the county, and he did not know of its existence. It is probable that those doubting the statements of Dr. Harkness confounded two lakes in the same vicinity.

The Trustees of the Academy have authorized W. N. Lockington to solicit subscriptions to procure the necessary books of reference to assist the curators in arranging and cataloguing the museum.

The California State Dental Association will hold its sixth annual session in this city on June 8th. The object of this association is to elevate the character and dignity of the profession, to establish uniformity in practice upon scientific principles, and to develop that desire for mutual cultivation, literary research and scientific investigation so much needed in all professions.

HEAVY MELT.—One day last week in the melter and refiner's department of the U. S. Mint in this city, 70,000 ounces of gold were melted and run into \$20 ingots. This is over two and a quarter tons of gold melted in one day. Who says the mines are giving out? This melt is said to be the largest quantity of gold ever melted in one day in any mint.

Home Industries.

The Bag Factories of San Francisco.

Among the important industries of San Francisco the manufacture of bags must not be overlooked. When we consider that the immense wheat crop of California exported, last year exceeding 8,000,000 cents, is packed into bags and so loaded aboard ships, it will be seen that the supply of bags must be proportionately large. To meet this demand the bag factories of San Francisco were called into existence.

Amount of Capital Employed.

It is difficult to arrive at the exact amount of capital employed in this business, but it is safe to say that \$500,000 would not be an excessive figure.

Number of Bags Used.

The number of grain bags used during the year 1873, was, in round numbers, 10,000,000. In 1874 the number was increased to 15,000,000 and it is estimated by a gentleman well qualified to judge that 12,000,000 will be needed for the grain crop the present season. Of course much the greater portion of these were imported, but there were manufactured over 2,000,000 grain bags in this city the last year, while a company in Oakland manufactured from the raw material as many more. In addition to those designed for grain 2,500,000 flour bags were manufactured here in 1874, and 2,000,000 small bags for salt, etc. In making these bags, 1,000,000 pounds of flax twine is used, besides a large quantity of cotton twine.

The Factories

Are all located quite near to each other, three being on Clay and one on Davis street, and competition is quite sharp between them. The uncertainty of the grain crop this year has had rather a distressing influence on the business, though in the past week it has rallied somewhat, as the prospects for a better harvest have brightened.

Neville & Co.,

At No. 113 Clay street, have forty sewing machines, twenty-one of which are in use. They now employ forty-eight hands, all men. A skilful workman will turn out in a day of ten hours, 1,000 grain bags, with a machine. This firm manufactures entirely by machine, and claim their goods equal to any hand sewed bags in the market. No. 105 Clay street is occupied by Neville & Co. for storing second hand bags, and manufacturing tents, a branch of the business in which they are largely engaged. At No. 115 Drumm street they also have a force of men employed in repairing bags. They import their own material and at present have several large invoices stored in the Bay Warehouse.

Detrick & Co.

This firm, located at No. 123 Clay street, have seventy sewing machines of the Grover & Bakern pattern, but in the present dull season only run fifty. They employ about 125 hands, mostly girls and boys. The machines are run by girls, and the boys cut the material into proper size, turn the bags after they are finished and pile them in stacks ready for compression by the haling press, which is worked on the hydraulic principle and is a model of its kind. The girls work entirely by the piece, and earn from \$5 to \$8 per week. The boys, some of them, make \$8 per week turning bags. Three examiners are constantly at work in the manufactory on the lookout to detect any imperfection in the sewing or the material of the bag; as an incentive to report anything like a flaw in the work, the boys receive a cent apiece for each defective bag reported. Connected with the manufactory is a printing press where all bags receive the firm trade mark or are labeled as desired. A machine shop and a skilful mechanic afford means for repairing any break in the sewing machines. This firm has sold since January 1, 1875, 1,080,000 bags of different kinds. Their manufacturing capacity is 30,000 a day.

The California Standard Sack Company,

Located at 36 Clay street, is a new organization formed for the purpose of manufacturing sacks of all descriptions, using for that work the Garland needle. This ingenious contrivance, the invention of Mr. H. P. Garland, is deserving of notice. The needle has all the appearance of a spiral spring, is about three feet in length and an inch in diameter. One end of this needle is sharply pointed, and in a groove along the whole length is laid the twine to be used for sewing. Three rubber cylinders of a length equal to the needle are provided. Two of these below form a bed on which the needle rests; the other is placed on top of it and as they revolve the needle is put in rapid motion. The material is fed to it. As it comes within range of the needle the point enters, carrying the twine through and pushing it along, repeating the movement until the end of the cloth is reached. The twine now appears in loops where each entry by the needle was made; but as the end approaches, by an ingenious device the bights of twine along the whole face of the material are gradually tightened until, as it drops from the machine, a close and even stitch is seen. The inventor feels confident that this needle will effect a revolution in bag making—it certainly works well thus far. The company have eight machines in operation, each of which will sew 1,000 sacks per day of ten hours. The best flax twine is used in sewing, and it is claimed the bags already offered in the market have been received with approval. The machines are driven by an engine of eight

horse power. Girls are employed to work the machines, and the sacks are turned by boys. The wages paid range from fifty cents to one dollar and a half per day. A machine is also in use for hemming the material ready for making into sacks. Mr. A. J. Gove is the manager, and evidently the right man in the right place.

J. & P. N. Hanna.

This firm, who are located at Nos. 308 and 310 Davis street, are largely engaged in the manufacture of sacks of all descriptions. They confine themselves, however, entirely to hand sewed work. The making of ore bags is a specialty with them. Coal sacks are also manufactured. They make at least 100,000 a year of the latter. Grain, wool, bean and potato sacks are also made, all sewed by hand. The manufactures of the Messrs. Hanna stand deservedly high in the market, and they are determined to maintain their excellent reputation.

Conclusions.

From the facts given above it will be seen that the manufacturing of bags is entitled to a place among our greatest industries. But what this business now is bears little semblance to what it may become in the future if the experiment, already ventured in a small way, of growing jute and flax within the borders of our State should prove successful. Where now hundreds of hands are employed thousands would then be necessary, and where we estimate the capital used by thousands it would be reckoned in millions.

HURDY GURDY.—We visited last week the Oneida mill, and observed the working of the machinery as now driven by the hurdy gurdy wheel as improved and patented by Mr. Knight of Sutter Creek. The wheel is of cast iron, eight feet in diameter, with peculiar shaped iron buckets attached. The whole space occupied by the wheel does not exceed four feet front by about twelve in height. The water is let on to the wheel through a three-inch nozzle. The fall from the reservoir to the wheel is 230 feet. About 200 inches of water is employed, and with that amount sixty heavy stamps are driven at a speed of eighty drops per minute, and this speed kept steadily up, without any variation. We never saw more perfect work or steadier power. In fact, from the rapid and uniform drop of the stamps, more rock can be crushed in a given time than by any other motive power we are acquainted with. With clear water there is no perceptible wear of either wheel or buckets, and in the course of twelve months running but very little cost for repairs would be incurred. It is astonishing to contemplate the amount of machinery that can be driven by so small a wheel and so small a quantity of water. These wheels are being generally adopted in all the mills in the county where water can be had, and will prove an immense saving over steam.—*Amador Ledger.*

SLICES.—What a terrible gauntlet of conditions—past, present and to come—the silver from our mines is compelled to run if, after once awakened from its bed in the shining depths where nature has built its home, it succeeds in making its escape. Six-mile canon is filled with dams and sluices for the collection of tailings, from beginning to end. The mills for their reduction are kept busy, and then half is not worked up. Thousands of tons are lying waiting to be run over and yield the glittering wealth which has escaped from the mills. The Consolidated Virginia are sluicing for a mile or so below their mill, and doing the thing systematically. Some of the tailings from this mill look like rich black sulphur ore, and yield \$80 per ton. Under the system of sluicing which has been inaugurated by them, there is but little of valuation which in the end escapes them. Gold Hill is also sluiced from the upper to the lower end, and then Silver takes it up and sluices on again. And now Charley Rooke is putting up four strings of sluices at the lower end of Silver City, opposite the bridge, which are to be one hundred and fifty to two hundred feet in length.—*Virginia Enterprise.*

SENSELESS OPPOSITION TO SCIENTIFIC EXPLORATION.—In an address recently delivered before the National Academy of Sciences, at New York, Professor J. P. Lesley, in describing the work done in connection with the second geological survey of Pennsylvania, said that operations were proceeding now in three districts or sections, one having its headquarters at Easton, and extending into Bucks county; another operating in the vicinity of York; and another in the Juniata valley. He said that one section of the state could not possibly be surveyed, and that was the oil region. The moment an assent was put into the oil region the oil men objected, more petroleum being now produced than the market would bear, and the party did not dare go there in order to make measurements on account of the fear of further discovery of oil-producing strata. Among the coal men also a like opposition to the operations of surveying parties was found, so that in those sections of the State nothing of importance could be done.

DISCOVERY OF VALUABLE IRON ORE IN NORWAY.—A large deposit of hematite has been discovered in Nordland, a district of Norway, about twenty miles from Bodo, and ten or twelve miles from a port entirely free from ice. It proves, on analysis, to contain between fifty-four and sixty-seven per cent. of iron, with only a very small percentage of phosphates.

"Petering Out"—California Mines.

The *Foothill Tidings*, published in Grass Valley, Nevada county, California, a short time since received a letter from a California street (San Francisco) stock operator, making inquiry about a Grass Valley mine. It was suggested in the answer to this letter that there were in Grass Valley mines not now working, which might be obtained on reasonable terms, and which were well worth the attention of capitalists. To this the "operator" replied that the Comstock was all the rage, and that people preferred to operate in stocks rather than work even a promising quartz mine. He said:

"The example of Allison Ranch, Empire and Eureka at Grass Valley, all very rich mines at one time, are not very encouraging, to say the least, and unless this mine can be easily and cheaply worked, and the vein promises good width and character, it would not pay to bother with it, as, without exception, so far as I know, the Grass Valley mines have 'petered out,' although very promising at times, and are very irregular in yield.

"I have some idea that the Washington and Eureka districts may turn out larger and better mines, but so far, even in those districts, the mines have not been very satisfactory. Failures have been the rule—some from one cause and some from another—and I believe that not one important mine is now being worked there.

"This aspect of the case goes to show that parties should 'go slow' in putting money into quartz mines in Nevada county. One here and there may be worked at a profit for a few years, but in the end they 'peter out.'"

To this the *Tidings* replies: "Making all due allowance for this letter as a 'bear' movement, without which it would be impossible for a California street operator to negotiate for mines, and still it is apparent that this opinion of Grass Valley mines prevails among capitalists to an alarming extent. Is there any foundation in fact for such an opinion? Let us see.

"Allison Ranch—to begin with those cited by our San Francisco operator—which during its day turned out a round two and a half millions in gold, was worked to a depth of only three hundred and forty feet—475 feet on the incline—and all miners who know anything about this mine and about its shutting down, unite in saying that there are many millions of profit in the old mine yet, with present modes and facilities for mining and milling. Empire, the old Ophir mine, has never failed of paying a profit to good management since its opening in 1851 to the present day, though under a cloud from bad management at several times. Eureka "petered out" the same as all the more prominent mines on the Comstock have at various times; the ore chute, which at one time made the Eureka known as the best mine in California, pitched and went off upon the ground of the Idaho. The same chute continues in depth and extends easterly upon the Idaho ground without limit, so far as is now known. Did Massachusetts Hill "peter out," after running two miles or more of tunnels, working two or three hundred men for several years and taking out several millions in gold? By no means. Square locations was the difficulty with this great mine. Three hundred feet is the greatest perpendicular depth reached and the ledge was left rich and capable of turning out its millions yet at great profit, because its pitch took it off the ground owned by the company having the works. The adjoining ground will sometime, it is hoped, consolidate and work the mine, showing California street sharps that a "peter out" here is not so very different from "one on the Comstock." The Gold Hill mine, which, up to 1865, turned out not less than four millions in gold, beside untold amount in the shape of "specimens" stolen by the miners, is anything but a "petered out" mine in the opinion of men who worked in it last. Skill and good judgment in the early working of this mine would have made it a paying mine to-day, and when capital gets enough of gambling in Washoe stocks some of it will go into Gold Hill and take out many millions more. New York Hill, after yielding half a million or over, "petered out," that is, it cost too much with the machinery then in use and under the then management, to keep the mine clear of water and raise and work the ore. All the miners who then worked in it said the mine was yet a good one and after several years of idleness is now proving that they were right. We might go on and enumerate a score or more mines that to a superficial observer look "petered out," but the phrase is not truly applicable to any mine hereabouts that ever made itself a reputation as a mine. Say if you please that some of our mines have disappointed the over sanguine expectations of such men as make haste to be rich, but not that they "peter out."

ZENGER has succeeded in obtaining photographic proofs of the sun and moon no less than nine feet two inches in diameter. He used a concave mirror instead of the ordinary object glass.

THIRTEEN thousand passengers arrived in San Francisco by steamer and rail during April. This is the largest number arriving in any one month during the history of the city.

Hydraulic Elevators.

The height to which buildings have now to be erected, owing to the concentration of business and the consequent increase in the price of real estate, has necessitated the employment of elevators to make the accommodation of the higher floors available. At first steam elevators came into use in the larger hotels and in buildings provided with a steam engine and shafting. The cost of operating them in establishments not already similarly provided acted, however, as a bar to their general use. This preventive to their extensive introduction has been done away with by substituting hydraulic for steam power. The great diminution in the cost and expense of operating an elevator arising from the utilization of the power furnished by the city water mains, places the convenience of one within the reach of all hotels, warehouses, stores and manufactories.

The manufacture of hydraulic as well as steam elevators has now become quite a business in all large cities, and a large number of patents have been issued for the various devices by which they are operated. There are a large number of elevators in use in this city, and the ordinary "hoisting apparatus" heretofore so generally employed in warehouses is fast disappearing before the more modern and more generally useful elevator.

Five elevators for the Palace hotel are in process of construction at the Risdon iron and locomotive works, which will be capable of lifting 100 persons from the ground floor to the upper seventh story in thirty seconds. They will be worked by hydraulic pressure. The great convenience of an elevator is now within the reach of all establishments of any importance.

DANGEROUS SOPHISTICATION OF SILK.—Silks are being adulterated with a material more dangerous to the wearer than the flour paste and China clay by means of which Manchester men improve the appearance of their calicoes. The French in this case are the offenders, but the fashion they have thus set is one which our textile manufacturers are never slow to follow. By treatment with salts of iron and astringents, and with salts of tin and cyanides, the weight of the fabrics has been raised in some cases by 300 per cent.; and, besides, the silk is rendered highly inflammable, burning like tinder if touched with flame, and liable, besides, under certain circumstances, to spontaneous combustion.—*Iron.*

THE effect of extreme cold upon the human body, according to Lieutenant Weyprecht, the leader of the second Austro-Hungarian North Pole expedition, has been greatly exaggerated. He says that it does not produce difficulties of breathing, pain in the chest, etc., as has been frequently stated. The officers and crew of his expedition bore the cold easily, though most of them were born in a foreign climate. Some of the sailors never once wore a fur coat. Even at the lowest temperature the officers were able to smoke their cigars in the open air, except when the wind supplemented the cold, when the latter became insupportable. The effect of the cold varies according to the quantity of moisture in the air and the state of the personal health; a degree of cold which at one time may be very disagreeable may be endured with perfect indifference at another.

FAST RAILROAD TIME.—The following telegram to the Chicago *Evening Journal*, in reference to the Chicago, Burlington and Quincy Railroad, reports the fastest time on record made with a full express train—other faster time, however, having been made in England, never in the United States, with a locomotive and single car: "Ancona, Illinois, April 29th. The Atlantic Express, conductor Howland and engineer Nixon, has made Mendota to Ancona, fifty-six miles in the unprecedented time of fifty-six minutes. Of the time lost (four hours) by a wash-out at Atlanta City, Iowa, last night, three hours and forty-five minutes were gained between Galesburg and this place, a distance of 126 miles. The run, so far, subtracting stops for dinner, watering and passengers, averages a mile in less than a minute and a half."

THE study of a mineral field progresses by a collection of facts from observation. These form a continual meditation with the mind, the process being, first a positive, then a negative and mediation, which is a starting point for a higher unity; and, when the necessary stadia have been passed, the mind going inductively from elements to principles, rises from the material to ideal, and strata and vein system of the mineral field are reflected or seen in the mind, as they existed before the ores were filled in the iron mountains or lead or copper veins.

PREHISTORIC RELICS.—In the coal shale at Wezikon, according to a Swiss paper, a series of pointed fire-poles covered with wicker-work have been found. These are referred to as being the most ancient evidence yet known of the existence of man, and belonging to the period intervening between the two glacial epochs.

EBULLITION OF SULPHURIC ACID.—According to M. Bobierre, sulphuric acid may be caused to undergo regular ebullition by the addition of thin plates of platinum in the proportion of 180 grains of metal to 32 quarts of acid. The whole is to be treated in a vessel of 55 quarts capacity.

SCIENTIFIC PROGRESS.

The Transit and its Probable Results.

The full result of the patient watchings by the various parties of the late transit of Venus, will not be fully worked up by the scientists for several months. The first proximate determination of the distance of the sun from the earth, hastily computed, comes from a French source, in the form of a letter addressed to the English astronomer royal, Professor Airy, and has been published by the latter. The computations are made by M. Paiseux, an astronomer of the Paris observatory, from eye observations at Peking, Chiao, and the island of St. Paul in the Indian ocean. The result announced for the solar parallax is 8.879 seconds. This is a somewhat larger parallax than the favorite figures now in use among astronomers, though not as high as some estimates that have been made. If correct it will reduce the distance of the sun to about 91,900,000 miles. Professor Newcomb's studies, in advance of the transit, led him to the belief that the distance would ultimately be determined between 92,200,000 and 92,700,000.

Soma of the Difficulties

To be met with in adjusting and comparing the observations taken at the various points were alluded to as follows by Mr. E. Colbert, at a late meeting of the Chicago Academy of Sciences: "I have called your attention at former meetings to the difficulties which will be encountered in the attempt to reconcile these observations—difficulties arising from, first, the irregular shape of the earth, which is not a true oblate spheroid; second, the irregular contour of the sun, its surface being in a state of perpetual commotion; and, third, the errors of observation, which may be regarded as an external kind of 'personal equation.' Summing the probable average of these three factors of error, I conclude that the astronomical world will be fortunate if it is able to reconcile all the observations so as to make it certain that the accepted average is not more than 100,000 miles in error, or one part in 900 of the whole distance.

"There is no reason to doubt that we already know the distance of the sun to within 300,000 miles. This is about one part in 300 of the whole distance; hence the probability is that observations of the transit of Venus in 1874, on which more than \$1,000,000 have been expended, and involving the equivalent of not less than two hundred years of labor on the part of one man, will only reduce the uncertainty to about one-third of its present magnitude; but this will be no mean achievement. It is not saying too much to claim that this result will be worth at least ten times the money and labor expended in obtaining it."

What Cheap Electricity is Expected to Do.

The recent improvements in magneto-electric apparatus, in which, as is well known, all expensive batteries are discarded, being driven by steam power alone, at an expense of five cents per horse power per day, have given such encouraging results that it is anticipated that by further perfection powerful electric currents may be produced cheap enough to perform the operations of manufacturing chemistry, thus far performed by batteries, the hydro-oxygen blow-pipe, by furnaces or expensive chemical reaction, as acids, alkalis, etc.

An inventor in London, (not named in the report from which we borrow the following details,) after having perfected a machine of the kind mentioned, driven by two and a half horse power and equivalent to 500 Bunsen cells, but costing only from twelve to fifteen cents per day to run it, is now making one equal to 1,000 such cells, by which he proposes to produce chemically pure copper, which is now worth from three to four shillings per pound, at the cost of ordinary commercial copper; potassium and soda at less than half their present price; aluminium, now at seventy-five shillings per pound, at thirty or thirty-five shillings, and magnesium, calcium, and other rare metals at prices which will bring them into commercial use. The inventor of this machine has even the courage to declare that he will purify two tons of pig iron from phosphorus, sulphur, carbon and silica in eighteen or twenty minutes, at a saving of two-thirds of the cost. This latter point may be very doubtful, but everything certainly tends to the probability of a glorious triumph in store for practical electrical science.

CURIOUS WATER FORMATION.—We were yesterday presented with a curious specimen of water formation found in the penstock of the Mountain mine, Silver mountain, Alpine Co. The penstock was sixteen feet long, and the water flowing into it formed four slabs, each sixteen feet long, one foot wide and an inch thick, with one side smooth and the other crystallized, the edges being beveled. The formation was deposited within four years. A large specimen is to be donated to the State library and another to the Agassiz institute.—*Sacramento Record, March 12th.*

SIZE OF A MOLECULE.—No person ever saw one, but Sir William Thompson thinks that if a drop of water could be magnified to the size of this earth the molecules would be as large as a shot, or possibly as large as a cricket ball.

Electricity—Interesting Observations.

M. Vikjander, during one of the recent Swedish expeditions to the arctic regions, made extended investigations into the electrical condition of the air there existing. All his observations agree, says the *Scientific American*, in showing that the atmosphere conducts electricity at temperatures relatively high, a circumstance to which may be attributed the absence of thunder and the presence of the aurora borealis. It has been suggested that this is due to the great humidity of the air in such regions; but it is evident that the phenomenon must be ascribed to other causes, since the same temperature and the same degree of humidity do not produce a like effect in lower latitudes. At less temperatures,—four degrees and thirteen degrees Fah., and below—the air isolates better. Generally the arctic atmosphere appears to be positively electrified, and the earth negatively. In several instances the air was effectively electric of itself, and this not due to terrestrial induction. During certain periods of the spring, at a time when the air isolated relatively well, both ground and air were charged with negative electricity. This change of the electrical state of the atmosphere was not a constant consequence of greater cold; but when the temperature had been lowered for some time the air had an evident tendency toward a negative condition.

There seems to be a natural connection between these facts and the aurora. During the months of January and February, the latter phenomenon appeared daily, and was especially noticeable on the 19th and 26th days of the latter month. It then disappeared, to reappear, however, on the 2d of March. At the same time changes in the electricity of the air were observed, suggesting the theory that the negative electricity, deprived of the possibility of discharging itself into the aurora, was obliged to accumulate in the lower atmospheric strata, which isolated relatively well. From the 2d to the 11th of March the aurora returned, and during this period the air was in a good conducting condition, or else, when effecting isolation, was positively charged. Subsequent to the latter date, the auroras ceased entirely, and an interval supervened, of low temperature with negatively electrified air, which lasted until the increasing light of the season of the year precluded further auroral observations.

CURIOUS EFFECT OF GAS FLAME.—Mr. S. J. Mixer notices a curious effect of a gas flame on the current of a Holtz machine. The jet consisted of a glass tube drawn out to a point, and the flame had a length of about an inch, and a diameter of only an eighth of an inch. Inserting this between the two terminals of the machine, the length of spark obtainable was increased from less than ten inches to over twelve inches, the full distance to which the balls could be separated. The same increase was not obtained on simply inserting a conductor between the two terminals, a ball an inch in diameter only lengthening the spark about an inch.

CURIOUS PHENOMENON.—A curious phenomenon was noticed during a recent balloon ascent by two experienced French aeronauts of thorough scientific attainments, M. Tissandier and M. de Fonvielle. They were able to hear voices from below, and remarks which indicated that the persons in the balloon were visible to the speakers, although at the time a cloud obscured the surface of the earth from the view of the aeronauts themselves. This occurrence is explained by the hypothesis that a cloud may be transparent and opaque at the same time, according as it may be viewed in different directions.

A NEW WHITE ALLOY.—The name "neogene" is given by M. Sauvage to a new white alloy composed of copper, 57 parts; zinc, 27 parts; nickel, 12 parts; tin, 2 parts; aluminium, 0.5 part; and bismuth, 0.5 part. It has a silvery appearance, is sonorous, tenacious, malleable and ductile, and is recommended for jewelry, as a substitute for silver in plate, and for low coinage. The new elements in the combination are those of the bismuth and aluminium. The alloy is very homogeneous, and is susceptible of a high polish.

OZONE.—According to Schoene, ozone is partly destroyed by passing through water. The extent of this action depends on the length of time the gas is in contact with the water and the surface exposed. Ozone is dissolved by water in small quantity. The quantity of ozone destroyed by the water is far greater than the quantity absorbed. Ozone does not oxidize water to hydric peroxide. Ozonized oxygen standing over water is converted into ordinary oxygen in about fifteen days, with change of volume.

AN EARTHQUAKE RECORD.—In examining some large saltpetre caves in Franklia county, Mo., the columns of spar that had been formed by the dripping of water, and reached from the roof to the clay in the bottom of the caves, had been fractured horizontally, each at the same level. Here was the record of an earthquake, probably that of New Madrid in 1811.

FORCE OF THE WIND.—During the tornado of March 4th, the vibration of the Cape May light-house was so great that the oil in the lamps spilled out of the bowls. A bucket of water had frequently spilled over during some of the gales which howl along the coast.

MECHANICAL PROGRESS.

Metallic Belts and Band Saws.

Metal bands can never be employed successfully for the transmission of power. A soft steel band one-twenty-fourth of an inch thick, running over a drum thirty-six inches in diameter, the latter revolving 350 times per minute, will last from 80 to 100 days, when it will break. After splicing it will run from about five to eight days, when it will break again; but at this time it will show several more cracks, and perhaps be found to be already breaking in two or three places. The metal band will not last one-fiftieth part as long as the leather band under these conditions. On smaller or larger drums the band will last a correspondingly longer or shorter period.

Band saw-blades also act in the same manner. Many an apparently sound saw-blade from one-fourth to one-half inch in width breaks every day or oftener, which it did not do when first put on. It has become brittle on account of the great number of times it has been bent. It is, in fact, what we call worn out. By using a band-saw when new, the blade being from one-fourth to one-half inch in width, it can be used up to one-eighth or within one-sixteenth of an inch without breaking.

According to a statement from a good author, metal bands also stretch—and very much too. Some were well tried about twelve years ago. Another objection, in many if not all cases, is the expansion and contraction resulting from differences in temperature, the band being at one time so tight that it would break, and at other times so long as to slip. This, however, could probably be obviated by a tightening pulley; but the use of this pulley would in many cases be inconvenient.—*Scientific American.*

Internal Grooving in Steam Boilers.

In the last annual report of the Hartford steam boiler insurance company we find, among many other not generally suspected causes of boiler weakening and consequent explosions, the following: This defect (internal grooving) arises from similar causes in the use of impure water. In a former report it was stated that internal grooving was caused principally by a disturbance of the fiber of the iron, caused by the effort of the boiler under heat to adjust itself to certain conditions. Thus a boiler, as is well known, is made of sheets or plates with the edges lapping one over the other. It will be readily seen that no matter how well a boiler is constructed its form can only approximate to a true cylinder. Hence, under internal pressure, the effort to arrive at a perfect cylindrical form brings an undue strain to bear along the inner edge of the lap, which, by being varied from time to time under different degrees of pressure, is effected very much as a piece of iron would be by bending it back and forth many times, only in less degree. Now, this continued variation from day to day, year in and year out, disturbs the fiber of the iron along the edge of the lap, and renders it more liable to the attack of acids in the water. It will be seen in these cases that the groove is narrow, and looks as though it had been originally cut with a tool. The grooves along the girth-seams are caused in a similar way. The heat on the bottom of the boiler expands it more than the other portions, and there is a tendency to cause the boiler to bend back and forth at a point or at points at right angles to its length. These points are along the edge of the inner lap of the girth-seam. The fiber becomes disturbed and loosened, and is consequently readily attacked by the acids in the water. Fretting of the boiler in its setting doubtless aggravates the difficulty. This defect has been attributed by some to galvanic action. One obstacle to this theory, however, would seem to be the fact that the corrosion is confined to such narrow limits.

BESSEMER STEEL WORKS IN SWEDEN.—According to the latest accounts, there are now thirteen Bessemer steel works in operation in Sweden. In most of these works great attention is being paid to the production of extremely soft steel, or rather what should be termed Bessemer iron, as when of the desired quality it only contains from 0.1 to 0.15 per cent. carbon, and at most should not exceed 0.2 per cent. carbon, in order to qualify it for making the soft steel plates, for which there is so great a demand. The Swedish steel makers have, however, found very considerable difficulty in keeping up a uniform production of this quality from the Bessemer converters, which are usually in Sweden fed direct from the blast furnace, not only because such almost pure metallic iron requires so high a temperature to keep it in perfect fusion, that it is much disposed to solidify and form sculls or crusts in the pouring ladles, but also because the metal thus nearly free from carbon is more apt to take up oxygen and become redshort, which can only be corrected by the addition of spiegeleisen, which in its turn is apt to introduce too much carbon as to elevate the percentage of carbon in the product above what was intended. These circumstances are now combining to make the Swedish Bessemer steel manufacturer very cautious as to taking contracts for large quantities of such soft steel, except at sufficiently high prices to cover all risks.

Progress of the Arts.

A most noteworthy illustration of the progress of some of our arts is this, that those who practice them are daily becoming not only more willing to lay by their older machinery but with haste and energy are throwing it out and bringing in a new.

It is hardly longer ago than yesterday that watches began to be made by cunningly devised machinery, which in nearly all of its details is less liable to error than the bands that made it, and yet this very perfect machinery has entirely supplanted and driven out of use, or at least out of a very wide market, the primitive hand fixtures by which the same work was done before.

Some of our iron mills have before now been spoken of, not with literal truth to be sure, but yet with a handsome margin in favor of the statement, as using acres of cog-wheels and similar fixtures in doing their work, and the too with each piece running into or against its neighbor with a rattle and a roar that needs to be seen and heard to be appreciated. Strange to say there are still those who retain in use these antique relics, but their balance-sheet will nevertheless rule them out before long, or else it will order a halt, more ruinous perhaps than an entire transformation would be.

Our technical schools, and the societies which are in a large measure their outgrowth, have done great things for our metallurgical enterprises, most of all, it is quite safe to say, in pointing out the way in which has lain the possibility of improvement, leaving those whose hands perform the actual labor of manufacture to draw in closely to the path thus shown and to bring up every detail that may be thus found to be in arrears.

One of England's best writers has said that there are rarely more than a very few in each generation who really take the great steps of industrial progress, by which their contemporaries and their successors find themselves advancing, so that the great majority of the rank and file can hope to do little more than to fill up as completely and richly as may be the great outlines thus sketched.

Five Hundred Shots a Minute.

A machine gun was exhibited and tested a few days since in the Twenty-second regiment armory. Mr. William B. Farwell, the inventor, operated and explained his invention. Among those who saw the experiment were Col. John E. Gowan and Col. Knox of the Ordnance Bureau, Col. Porter and many other officers of the National Guard.

Mr. Farwell's invention consists of ten steel barrels of twenty-five calibre, arranged exactly parallel to each other in a metallic frame. From center to center of the outer barrels is three feet. Each barrel is charged separately from a magazine containing fifty rounds of ammunition. The charging, firing and extraction of exploded shells are all accomplished by the turning of one crank, at each revolution of which the whole ten barrels are discharged, emptied and reloaded.

With relays of magazines five hundred shots can be fired a minute. A system of cog wheels connects the firing crank with a traverse, and each turn of the crank traverses the exact width of the target. Thus the gun is automatic in this particular, designed to pick off a line of battle in regular detail.

Its points of difference from the Gatling gun are in the simultaneous loading and firing of ten barrels, the latter loading each barrel through the same magazine aperture and firing but one shot at a time.

Mr. Farwell had only one magazine at the trial yesterday, so the actual rapidity of fire attainable was not demonstrated. The fifty shots contained by that one magazine, however, were several times fired in six seconds. The appearance of the target after firing, all the shots having struck at about the height of a man's breast, showed how irresistibly destructive such a weapon would be in a street fight or in resisting a charging enemy.—*N. Y. Sun.*

AN IMPROVED BLOWER.—Mr. D. P. Morrison, of Newcastle-on-Tyne, civil and mining engineer, has patented an invention which refers to ventilators, fans, and blowing machines, and consists of a casing having one or more inlets and outlets, and of blades made to revolve in the casing, so as to draw in air at one part and discharge it at another part. The provisional specification describes the construction of blades so that they widen out towards their periphery, and are slightly curved in a forward direction; also the making of the inlet or inlets of funnel shape or conical; also where there are inlets on both sides of the casing, the employment of a disc in the middle of the fan to prevent the opposite currents interfering with each other.

A NEW PROCESS FOR ORNAMENTING METAL SURFACES.—has been recently invented in this country. It consists in plating, electro-plating, or otherwise covering a plate, bar, or ingot of soft metal, and then rolling out or pressing the ingot into a sheet; whereby the coating is broken into irregular forms, and a marbled appearance produced on the surface of the sheet.

A KENTUCKIAN has invented a street car, the motive power of which is compressed air, effecting the same as steam upon an ordinary engine. The seats of the car are the air reservoirs.

AFTERNOON SESSION.

The Mining Stock Market.

The prices of mining stocks this week have been even lower than they were during last week. In fact the bottom seems to have dropped out of the market altogether. Ophir, the great leader of the market, touched \$35 on Wednesday, the lowest price for many months. The transactions in this stock, however, are very large, as they are in California at this present prices. All other descriptions of stock sympathize with the leaders and the prices of all are "off." There is no more reason for this sudden depression than there was for the recent rise. There is no use, however, in trying to account for the depression. It is evident, however, that the market is very much "off." The price of the Ophir stock has fallen from the 1600-foot level of the Ophir shaft and run perpendicularly through the ore to the west wall, owing to the regular easterly dip of the ledge; but since then it has been following the ledge itself in the form of an incline, and at the bottom of this incline was, at last account, ore assaying over \$300 to the ton. This would indicate that the ore vein is all right.

Chronicle, May 15: The Zacatero is about to resume operations under a new firm. Ore at the Josephine continues to be excellent. The company have leased the Zacatero mill for four months, for prospecting purposes. Mina Rica, sinking.

COLUSA.
QUICKSILVER.—Colusa Sun, May 15: The Abbott mine is taking out about three flasks a day, and now has on hand about 130 flasks, and 65 cents is the best price the company has been offered for any now on hand. An assessment of \$3 a share has been levied on the capital stock of the mine. This will pay up the entire indebtedness of the company and leave it with some \$40,000 worth of improvements on hand, and it is believed that the mine can be run with some profit at 50 cents a pound. The Buckeye is taking out plenty of ore, but we are not advised of their exact operations. The Messrs. Rethburn have opened a very rich mine, on a line between the Buckeye and the Turner, and will put up retorts. They have the best looking ore we have seen.

CONTRA COSTA.
IMPORTANT QUICKSILVER DISCOVERIES.—Contra Costa Gazette, May 15: Mr. J. F. Carey, Mr. A. S. Howard and others, within the past two weeks have discovered rich quicksilver ore in large quantities on the respective quarter sections owned by them in the Marsh creek canon, and last Sunday a party from Clayton, E. O. Chapman, Mr. Ryan and others, prospecting in that vicinity, struck an outcropping vein of cinnabar rock which they traced distinctly for several miles across the hills in a southeasterly direction until it was lost in the San Joaquin plain. Mr. Chapman, on Monday, left with a number of pieces broken from various portions of the ledge outcrop, and several experts who have examined them declare them altogether the best surface specimens they have seen from any of the quicksilver districts. There is little room to doubt that this is one of the most important and valuable quicksilver discoveries that has yet been made in this State; and we congratulate our readers who have located claims on their cheering prospects.

MARIPOSA.
QUARTZ SPECIMENS.—Gazette, May 15: Mr. George Boswell, of the firm of Landrum, Boswell & Allen, who are associated together for the purpose of developing the quartz veins which together they have located on Italian ditch, Chowchilla, brought into our office and presented us with several specimens of ore which he had taken from the croppings of what is known as the Boswell lead. The specimens are pregnant with free, coarse gold, and we have no doubt that this section of country, which is only about ten miles in a southeasterly direction from the town of Mariposa, will prove valuable mining district. Mr. Landrum, who the principal discoverer of the veins in this district, has, for the past year, been engaged in searching for veins and placer mines, and has been conclusively that gold in sufficient quantities exists to justify working. We shall turn our attention to this locality, and anything worthy of note we shall give our readers. At the same time we would suggest at this mining section, which promises to be of importance, be styled the "Landrum district."

APA.
LOCATIONS.—Calistoga Free Press, May 15: Out two miles in a southerly direction from Calistoga, ten quicksilver mining locations have been made. Four tunnels have been run from twenty to thirty ft. There is a marked resemblance in formation of surface rock to that of the Sulphur Banks Q. V. mine, Colusa county. The ore has been advanced and found to yield well. Surface rock averages one and one-half per cent., and will pay to work. Good road leads to the mine, and there is abundance of wood and water in the immediate vicinity.

NEVADA.
RICH MINE.—San Juan Times, May 15: The North Bloomfield gravel mining company have recently struck a bed of fine gravel which is lying immensely. This strata was struck near the of their numerous tunnel shafts and only a few ft below the surface gravel, and about sixty or eighty ft above bedrock. It extends to Brock and grows richer as they go down. The company is now washing through two monitors, using 3,000 inches daily. Their dam Bowman's is filled with water, and if no accident occurs they will have a sufficient supply of water to keep the two monitors at work until the fall rains set in. The company now employ about fifty laborers, half of whom probably are Chinamen.

NEW YORK HILL MINE.—Foothill Tidings, May 15: We learn from Mr. J. D. Meek that the new hoisting works were started on Thursday and that everything worked smooth. The machinery consists of two tubular boilers and engines. The pumping engine is of twelve inch cylinder and thirty inch stroke, and that of hoisting is a ten inch cylinder with thirty inch stroke. All the necessary accompanying gear is in perfect running order and the works can be placed on the list as first-class—among the best of the mine improvements of Nevada county.

The incline is now completed and the cars making their regular trips, loaded with quartz that shows the yellow metal quite clearly. New York hill, with the first level below the tunnel and large "hacks" above ready stopping, all yielding number one milling may be considered as having bright prospects before it. We understand that the mill

now being used by the company is about to be enlarged and improved to meet the requirements of the mine.

YUBA MINE.—A letter from Superintendent F. A. S. Jones, of the Yuba mill and mining company, above Washington, in this county, gives the following intelligence concerning this valuable property: Work is being prosecuted with energy on both ledges, and both are turning out splendid quartz, which shows well in free gold and rich galena sulphurets. He expects to have his mill ready for work about the 17th inst., and as he has a large amount of ore on the dump we may look for good reports from the Yuba soon.

GASTON RIDGE MINE.—This mine, which we have heretofore noticed as being again in course of development, after having laid idle for a number of years, is making a splendid showing. The drifts being run on the ledge from the new tunnel have exposed a vein two ft in thickness, which shows well in free gold throughout. Experienced miners who have recently examined the mine say that it is a remarkably rich development, and that the Gaston Ridge gives every promise of proving a great mine. The ground now being prospected is much deeper than any previous workings, and the new tunnel gives several hundred ft of backs, which will enable the company to take out rock easily and cheaply. They have also a good ten-stamp mill on the mine, with power sufficient to increase the stamps to thirty if required.

PLACER.
TUNNELING.—Placer Argus, May 15: From Mr. Joseph Price, one of the engineers of the Gold Run ditch and mining company, we learn that the work of tunneling for the Cedar mining company is being rapidly pushed to completion, and he thinks that the flumes will be put down in about two months. The former company is also extending their own tunnels, but to what extent they expect to run them we are not advised. There is no doubt but the companies which have expended immense sums of money to dig these tunnels will be amply rewarded for their outlay as soon as they can get to work, as there is no doubt that there is yet millions of dollars of hidden treasures, and the work of getting it may be said to be only commenced.

CHROME.—Placer Herald, May 15: The chrome discovery recently made a few miles from Auburn is a perfect success. An agent, representing the Chrome reduction works of Baltimore, Md., has recently visited the mine, and pronounces the ore fine in quality; and by way of backing his judgment, has contracted for all the parties can take out, agreeing to pay therefor \$11 per ton, delivered in San Francisco. One of the owners, Mr. Aubrey, told us that he thinks the ore can be mined, hauled to the depot and freighted to San Francisco at a cost of about \$5 per ton, thus leaving them \$6 clear on each ton. The extent of the deposit is, of course, not yet fully known, but \$6 per ton, of all in eight, will amount to no small sum. The prospects are at present that this will prove to be better property than the best gold mine in the country.

SOLD.—The ditch supplying the mines at the Bluff has recently been purchased by Breece and Wheller, for \$30,000, who propose to expend as much more this coming summer in enlarging and improving it. They expect to increase the capacity of the ditch from about 500 to 1,000 inches; shorten the route about four miles, by cutting a tunnel 1800 ft long, and extend it to Bath, which latter project, it is supposed, will greatly stimulate the mining interests at the last named place. This, in connection with other enterprises now in contemplation for that section, will undoubtedly make things lively there for some time to come.

PLUMAS.
HALLSTED CO.—Plumas National, May 15: The works of this new company are just above 12-Mile Bar, or at what is known as Kingsbury's. The Hallsted Bros. have entered into a contract with the new company to bring 800 inches of water from Kingsbury's creek to the claims. The water will be conveyed in a ditch to the East Branch, and taken across the river in 15-inch iron pipe, it being necessary to have about 2,000 feet of pipe for the purpose. The water privilege is a good one, and will furnish all the water required by the company for at least eight months in the year. The claims are extensive, and there is no reason to doubt their proving valuable and remunerative. The gravel is from 125 to 150 feet deep, is easily washed, and shows no clay or large boulders as far as it has been worked. It also carries gold from the surface to the bedrock, and every indication is favorable for a regular paying gravel mine. We think the new company have made a fortunate investment of their money. Mr. A. D. Hallsted will have charge of fitting up the claim, and as he has had upwards of twenty years' experience in the mines—most of the time on the East Branch—there is no doubt but that he will have everything in apple-pie order when the work is done.

SAN MATEO.
SILVER.—Daily Alta, May 11: A specimen of silver, containing about 300 ounces of silver to the ton, according to report, was brought to the Alta office yesterday. A glance shows that it is rich in metal. It was taken from a lode on the land of Martin and Larco, near Seaverville, in San Mateo county. The miners are so sanguine that they have paid \$2,000 for the exclusive privilege of working the lode, and they agree also to deliver to the land-owners thirty per cent. of all the ore taken out. Ten men are now at work there.

SANTA BARBARA.
SANTA YNEZ DISTRICT.—Santa Barbara News, May 15: A vein of cinnabar passes through the Santa Ynez valley, running east and west, almost parallel with the river. For full six miles the ledge is distinct, and has a width of from 50 to 200 feet. There are three distinct mines now opened.

SONOMA.
MIXING ITEMS.—Russian River Flag, May 15: William H. Thompson, living seven miles east of Gnenoc, Lake county, has discovered on his place, what is pronounced by experts a very large ledge of copper.

Work has been suspended on the Rocky Bar, Inyo district, and also on the Annie Belcher, Cinnabar district.

The Oakland mine, Cinnabar district, has shipped to Healdsburg since last Thursday 51 flasks of quicksilver. In the lower tunnel they struck a splendid body of ore this week. That tunnel is now in 300 feet and the last 80 feet is in good retort ore, but the body reached this week is the best they have ever struck. They will erect a furnace at once. The retorts will soon be shut down.

The Geyser is taking out about 20 flasks a week.

The Battlesnake will start up next week.

The Sonoma, which has been stopped for a few weeks for repairs, will start its furnace again June 1.

The Blue Jacket will resume work next week.

The quicksilver outlook is brightening.

The Mt. Jackson, Guerneville district, struck rich ore in a new place last Tuesday. Col. Abbey brought up yesterday the best sample of ore from that mine ever found there. The company have discharged all their white men, and intend to employ Chinamen. Economy is now the watchword.

STANISLAUS.

QUICKSILVER.—Stanislaus News, May 15: Quite a lively quicksilver breeze has been raging for the past week at Grayson. The contagion is undoubtedly spreading to Modesto. The excitement has been occasioned by the discovery of cinnabar in the Coast Range, west of Grayson. In several claims the croppings of quicksilver, as well as other favorable indications, have been discovered. The claim of the Oristimba prospecting company is, it is believed, at present ahead in developments. It is situated at the head of the north fork of Oristimba creek, and though but little work has yet been done, a well defined vein or ledge has been discovered, containing a fair per cent. of quicksilver.

TRINITY.

PAYING BIG.—Trinity Journal, May 15: Trotter & Smiley, of Douglas City, made another clean-up this week, taking out \$4,200 for a run of sixty hours' water, including probably \$500 left in the flume from last clean-up. This mine is good for fifty dollars for every hour they have water.

J. A. LYTLE writes W. J. Tinning, that Lytle & Hawtack are producing seven tanks of quicksilver daily with their retorts.

RETURN.—The prospecting party we spoke of a couple of weeks since, which started with a view of prospecting the main South Fork and its tributaries, returned last week, after a general look at the section. They report a number of miners as already located there, most of the bars on the main stream and the water privileges which might be made available to work there are taken up.

TULARE.

MINING INTELLIGENCE.—Tulare Times, May 15: We have had the pleasure recently of gaining some interesting facts from Mr. Geo. W. Brown and Prof. E. G. Moss, of the proposed development of the Mineral King mines during the present season. The machinery for a saw-mill, to be built in the district by the company which Mr. Brown represents, is now being shipped to this place, and will be packed the remainder of the distance without delay. The company will establish a first-class assay office in a week or two, which will be conducted by Prof. Moss, a thorough and experienced assayer and metallurgist.

TUOLUMNE.

THE MARKS AND DABROW.—Tuolumne Independent, May 15: This mine is progressing rapidly. Their new hoisting shaft is within ten feet of the main vein and will cut through a solid body of quartz, not less than from eight to fifteen feet wide, and which has been proved to be very rich—both by mill process and assay—the sulphurets alone giving two thousand and thirteen dollars per ton, and is supposed to carry about one ton of sulphurets to eight tons of quartz. They are also prospecting with their little mill, and have proved beyond a doubt that their very poorest rock, will mill not less than ten dollars per ton; and their average rock not less than one hundred dollars per ton—some of it milling over two thousand dollars. We notice, also, in the vicinity of this mine, that there are other mines going ahead. We will mention the Parallel quartz mine owned by W. Martin and Captain Back. They are energetic men, and will make their mine a valuable one.

At the Soulehyville mine, rock is being taken out that is worth \$150 to the ton, and plenty of it, too.

Nevada.

WASHOE DISTRICT.
CALIFORNIA.—Gold Hill News, May 13: The ore developments on the 1400-ft level are of a much better character than was expected, and

the developments already made place the California, in point of bullion production, side by side with its twin sister, the Consolidated Virginia. Sinking the C & O shaft is making rapid progress, the rock in the bottom blasting out finely. The foundations for the new powerful machinery are rapidly approaching completion.

OPHIR.—Daily yield, 150 tons of ore, mostly from the 1465-ft level. The ore stopes and breasts are all yielding well, and look promising for the future. The northeast winze, 100 ft north of the north winze on the 1465-ft level, is down 100 ft, the bottom still in excellent ore. The winze below the 1600-ft level, after striking the west wall, was inclined with the ore vein, which at this point has an inclination of 46 degrees to the east and north, and is still being pushed downward with all the energy possible, the bottom still in rich ore. Assays from the bottom of this winze this morning exceeded \$300 per ton. The east drift from the main shaft on both the 1500 and 1600-ft levels are being pushed vigorously ahead, the faces of both showing a favorable change in the character of the material penetrated, with strong indications of soon reaching the main ledge. On the 1700-ft level cross-cuts Nos. 2 and 3 have again been started up. These cross-cuts are 100 ft apart, cross-cut No. 2 being 120 feet north of the south line. The erection of the new machinery is making steady progress. Three mills are now kept steadily crushing ore from the mine, and the prospects have not been brighter for months past than at the present time.

CONSOLIDATED VIRGINIA.—Daily yield, 450 tons of ore, keeping the mills all steadily running. The ore breasts on both the 1500 and 1400-ft levels are yielding finely, and show no signs whatever of a diminution of the amount. The yield for the past month, owing to the dropping off of the Occidental mill for repairs, was a little over \$1,500,000. The usual dividend of \$10 per share, aggregating \$1,080,000, was paid on the 11th.

SIERRA NEVADA.—The several prospecting drifts in the old upper workings of the mine are all being driven ahead, with some very favorable prospects of the development of ores that will pay well for milling.

BELOKER.—Daily yield, 500 tons of ore. The ore breasts and stopes show no change whatever. The up-raise from the 1100-ft level, to connect with the air shaft below the 1000-ft level, will complete the connection in about 10 days more, thus securing the thorough ventilation of the entire mine to that depth. The mills are all kept steadily running, and everything in and about the mine looks prosperous and bright.

CROWN POINT.—The average daily yield of this mine for the past year has been 550 tons of ore, and the production shows no evidence whatever of being yet exhausted. The ore breasts are all looking well and yielding finely as usual.

BULLION.—The extremely hot weather has added greatly to the discomfort of the men at work in the east cross-cut from the main north drift on the 1700-ft level during the past week.

ORIGINAL GOLD HILL.—Cross-onting and opening the ore body at the 340-ft level south progresses very satisfactorily. Cross-cut No. 2 south is going ahead and will also soon be into the main ore body. It already showed good milling ore.

OVERMAN.—Draining the water from the shaft is making steady progress. The prospects of this mine on the lower levels was very favorable at the time the heavy flow of water was struck, and considerable expectations are fixed upon the results when the mine is once more drained.

NAGARA.—Sinking the shaft is progressing finely, the bottom still in quartz and ore of a very encouraging character. Streaks and spots of the ore are of a high grade, with every indication of the development of large bodies of ore when a greater depth is attained.

BEST & BELCHER.—Driving the south drift from the bottom of the winze on the 1700-ft level, to connect with the north drift from the Gold & Curry shaft, is making steady and favorable progress, notwithstanding the extreme hardness of the rock penetrated.

PROSPECT.—The rock is softer in the face of the tunnel, and small quartz seams and other indications show that the main ledge is not far off. The new three-compartment working shaft is down 26 feet, and the work is going ahead lively.

FLORIDA.—The donkey engine placed at the east side of the shaft has hoisted all the water out, so that a station is being opened at the 430-ft level for a drift west to the ledge.

LADY BRYAN.—The cross-cuts on the 180 ft level are all looking more encouraging than at any time in the past. The south cross-cut on the 170-ft level is in a mixture of white quartz and red oxidized ore of a very promising character. On the 80-ft level preparations are being made to extract ore for milling.

BUCKEYE.—Driving the west cross-cut on the 550-ft station is still making good progress, not yet having reached the west wall. This drift has penetrated a body of ore 40 ft in width that gives average assays of over \$10 to \$20 per ton. The ledge at this point is over 85 ft in width, and is of a very promising character.

COAL ON THE COMSTOCK.—The Virginia City coal company will soon supply fuel to the Bullion hoisting works, from their mine in El Dorado canon. Several other hoisting works and mills in Gold canon are about adopting coal in place of wood, as it is much cheaper.

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Fourteenth Lecture Delivered before the University of California College of Agriculture, on Monday, February 8th, by Prof. O. E. BESSEY.

Maples, the Grapevine Family, Mahogany Tree, Flax, Etc.

The first group we take up to-day is the group of the maples, now regarded as a sub-order, but, as the remainder of the order is of no importance, we can treat it by itself. The maple, *Aceraceae*, are usually as a sub-order of the soapberry family. As I said before, this is ranked as a sub-order as it stands, including only the maples. It is made up of less than one hundred species, all of them trees. Some of them are of very considerable magnitude.

First is sugar maple, it is commonly called in the East (*Acer saccharinum*), on account of the sweetness of its juice; starch and sugar are very largely made from it. The wood is light in color, of heavy weight and very firm. The wood being very hard, it gets the name, popularly, of hard maple. It is quite durable and when it takes on a peculiar wavy form known as curly maple, it is very highly prized. That is sugar maple.

Next is *Acer rubrum*, the red or soft maple found east of the mountains. The wood is generally lighter as to weight and is softer than sugar maple. Where moisture can attack it, it readily absorbs it, and if kept continuously moist, it very soon decays. It is, however, used largely for making chairs and the cheaper sort of furniture. As it is not very much inclined to split, almost all the cheap chairs brought from the East are made of this soft maple.

One or two others grow east of the mountains, but remember these two, *Saccharinum* and *Rubrum*, stand as the types of two groups. Now, on this coast, we have no hard maple at all.

Acer macrophyllum, a large tree, called also Oregon maple, is found in Oregon, and in the northern part of this State. It is a soft maple, so it can be used just where the red maple of the East is used, but if put out of doors and subjected to alterations of moisture and dryness, heat and cold, it very soon decays and becomes quite useless. This also now and then becomes somewhat curled, and is then called curly maple.

The striped leaf maple, (see Fig. 1), *Acer negundi variegata*, is a new variety of maple, being white and green. It is now seen in many American and English gardens. It grows to a height of fifty feet and has a most luxuriant and spreading foliage. The form of leaf is shown in the lower corner of the engraving.

The next one is box elder, coming under the genus *Negundo*, species *aceroides*. It now is found throughout almost all parts of the United States, east of the rocky mountains. It is a small sized tree with wood very much resembling the maples. It is usually ranked among the maples. Botanically, it is merely an ally. Sometimes it is called the ash-leaved maple. For all practical purposes it might just as well be considered a maple tree and used just as we use the soft maple. Its wood is not as hard as the hard maple of the East, and so cannot take its place. On this coast an allied species is found. I do not recollect its specific name. I don't know that it ever has been brought into specific use as yet. I have been told a little use has been made of this box elder for the blocks for wood cuts. When carefully prepared and dried, I think oiled, too, first—it takes on a texture which makes it valuable for wood cuts.

The next group is the vine family, or, as it might be called, the grape vine family, including all the grapes and nearly allied plants of the order *Vitaceae*. About three hundred species are known, found mostly in temperate climates, although somewhat inclined to run into the tropics. It cannot be considered a cold-blooded group by any means, as it always keeps pretty close to the warmer climates. It derives importance from one plant, the grape, and of this there are several species in cultivation. The first, and most

Important to the People of California.

Is *Vitis vinifera*, the so called European grape. It is a misnomer, however. It is no more European than the apple, peach, plum and those things are European. It has been cultivated from time immemorial. Its native countries, perhaps, are those bordering on the Mediterranean, especially the Eastern portions. It is said to have been introduced into England by the Romans. It is not a native there and since the time of its introduction it has been very considerably grown as an edible fruit, not for wine nor for raisins. In Southern Europe, as well as all the adjacent country lying east and

southeast, as the summers there are long enough and steady enough, that is, a long continued, hot season, this is favorable to the proper ripening of the grapes. As to uses, these may be divided as I have divided them here on the board. They are used either raw or manufactured. Are edible used as preserves and manufactured into raisins, wines, vinegar, etc. Now, east of the mountains we find that our grapes can only be used well in the first state; that is, as raw materials, raw products, while the grapes on this coast, very many of them, seem to be very well adapted to the manufacture of raisins and wines.

In Europe, as you pass southward, raisins which can be manufactured are largely grown. Northward, the varieties are grown which have to be used in the raw state. Those used raw are northern, those manufactured, southern ones. You will find this to run right through the whole world, if you take the matter up pretty carefully. Now, this is due to several things. In the first place, those grapes from which raisins can be made are mostly tender and are, therefore, grown in southern climates, and in the second place, generally in all the northern climates we do not have heat enough, long enough summers, for properly ripening up the grapes. So, if they do make any wine at

need not stop to discuss raisin making or wine making. You can get very much fuller information from little manuals that are published and from lectures that will be given here after a while on that subject. One thing may be mentioned as a key to the whole matter. In wine making, grapes

Must be Allowed to Become Fully Ripened.

In a great many instances the wine is sour because people are not willing to leave their grapes on the vine to become properly ripened, and gather them too soon for manufacturing.

I heard a gentleman upon this subject two or three years ago, who was fully posted on this matter. His advice for making good wine was, first to wait till the grapes were thoroughly ripe and then to allow them to stay two weeks longer on the vines and you may be sure that you can get pretty good wine from them. [Student.—"I should think they would dry up.""] Well, he said that they would begin drying. The way we usually do in the valley and the way it is done here in America is to wait until they are colored, wait until the color is pretty good. [Student.—"Here they wait until the grapes get exceedingly sweet and then they pick them.""] Something was said about the grapes from the same vine differing. Some may not be as sweet as others. Very few Cali-

northern portions and up in the northernmost part of the Eastern United States, is called the northern summer grape. From it we get good forms, as the Virginia seedling, Herbmont and many others. Some varieties only get about as far north as Cincinnati or Cleveland. The Northern fox grape, *V. labrusca*, is found growing all over the tallest trees and produces a large berry. From this is derived the Catawba, which is a wine grape of the East. All through the lake region you will find enormous vineyards of Catawba grapes, and also along the rivers.

Along the Ohio, Mississippi and Missouri rivers are vineyards of it. The Concord grape, from which a very red wine is made, is derived from the same one from which we get the Catawba.

The Isabella is from the same origin and the Hittford Prolific and perhaps a dozen or two more.

A few years ago one of our foremost growers in the East made some experiments with reference to improvement, so as to bring in the good taste of the European grape along with the hardness of our American variety. He hybridized this *Labrusca* with the European, and obtained a new sort, a fair grape with fruit resembling the berry of Europe, having much the same color and form and many of them very much the same taste, while many of them had the hardness of the original ones. I think the Black Prince is a foreign grape. I am not familiar with the varieties. You see these are split up into myriads. I have here only given the principal varieties.

I think, although it is a little outside of economic botany, I will call your attention to one insect that we have given a great deal of attention to in the Mississippi valley. It is

The Phylloxera.

Do you know it here? Is it a common name with you?

The *Phylloxera vastatrix* is a little root plant louse. It gets on the roots, stays there, sometimes two or three feet under ground, and wherever it stops it makes a little gouty swelling, so that you take up a root of a vine troubled with this, and instead of being elongated like that without any swellings, it will have little humpy swellings.

If you want to know whether your vines are troubled with this, just examine the roots affected with swelling. The particular fact that connects this to economic botany is this: From very careful examination for many years, investigators have, in the Mississippi valley, come to the conclusion that this insect is the cause, in a certain way, of grape mildew; that this insect, working upon the vine, weakens it so much that the grape mildew, *Erysiphe Tuckeri*, can take hold of it. This is not proved as yet, but it is so nearly proved that it perhaps may be given as almost demonstrated. Experiments to prove or disprove this will be finished in a year.

In very many cases these fungus plants do act in just this way. Now, as you have mildew here in the lower lands, I have no doubt there is *Phylloxera* there.

(Continued next week.)

Fig. 1. STRIPED LEAVED MAPLE.

all in the north, it is exceedingly harsh and sour and not at all fit for drinking, so that the world is necessarily divided into certain belts, as you may say.

Then another thing that comes in is this: Taking these grapes as they are brought into this country, into the United States, we find that this European grape, so called, having been cultivated for a very long time, has been in fact improved so that it has the proper qualities.

For Wine Making and Raisin Making.

While the American grapes, which are mostly grown eastward beyond the mountains, have not been sufficiently improved. Now, on this coast I find that the European grape is the one mostly grown and from it the wine and raisins made on this coast are mostly made. [Student.—"I don't understand how the European grape is better than the American.""] Well, it is just this, I will explain that more fully in a moment. The European grape has been grown probably three, four, or five thousand years. It has been cultivated, as you may see, moulded over from its former wild condition to a condition that is a considerable change from its original form, has very many of those stronger acids worked out of it, is considerably sweetened, its desirable products increased, the undesirable decreased, simply by long cultivation. Now, when we take this cultivated one and put it by the side of our American grapes which have been only in cultivation about two or three hundred years, you see here on one hand four or five thousand years of cultivation, and on the other comparatively a very short time. That has much to do with the matter. I suppose that a few thousand years hence our American will be as good as these, possibly. I

fornia wines can compete yet with European wines. Considerable influence or pressure must be brought to bear to make them compete. A good wine merchant behind a cargo of wines, of course, will make it compete.

That fact shows some mistake in the wine making. I suspect it to lie right here. I don't say it is in the climate. If anything, I should say California climate is better than the climate of many portions of France and Spain for the culture of grapes for wine. However, that is a topic that does not especially belong to economic botany.

The grape is known throughout the Eastern United States. When the people came across from Europe, of course they brought European grape vines. In a few years they found they could not grow them. They were naturally tender and killed down in the winter, and were subject also to a great many diseases which characterized them, and mildews and certain little insects that got on the roots of the vines, so that for a while they were compelled to fell back upon the wild grapes in the forests. They took these and have been cultivating them some 150 or 200 years and in this time have succeeded in getting some very fine grapes indeed. They are not the same we have here. There are in the East many species. Some of the varieties derived from these are brought over here. First, *Vitis riparia*, which we call the River Bank grape, a rather late growing grape, which has small berries. From it we have derived the Delaware, one of the most delicious of the table grapes. The Clinton, which is the opposite of that, sour as can be, very red however, is derived from the same original.

V. californica, which grows all through the

MINES ABANDONED IN MEXICO.—G. H. Howard, who has lately returned to Tucson, Arizona, from Sonora, reports depredations by the Chiricahua Apaches, in Sonora, of the grossest nature. Several bloody encounters have lately taken place between Mexicans and raiding Indians, the latter being driven off only after severe fighting, and afterward returning to the reservation. The whole of the Sonora frontier is in a state of constant alarm. Large portions of the cultivated lands are abandoned and mines unworked on account of the constant depredations of the Apaches.

THEY are having trouble on account of Chinese labor, at Bear valley, San Bernardino county. A number are employed there by the Gold Mountain company, and a few nights since a quantity of giant powder was exploded beneath the houses in which they sleep, knocking it to pieces, but strange to say not seriously injuring any of the inmates. This result was owing to the fact that the men who occupied the lower bunks were at work at the time. A reward of \$250 has been offered by the company for the arrest of the perpetrator.

FIRE CLAY.—R. V. Borden, of Reno, Nev., writes us that in his opinion there is as good an article of fire clay at that place as that mentioned by us as occurring in Cerro Gordo district, Inyo county, Cal. He states that he has seen common hand made brick in the same furnace with imported fire brick, and that they stood the heat just as well. This bed of fire clay is only about two miles from the railroad. Mr. Borden will take pleasure in sending some of this clay to any expert who may desire to examine it.

THE Dutch Hill mining company, Plumas county, cleaned up last week \$6,500 from the head of their sluice. They expect about \$20,000 from a twenty days' run. This company bring their water thirty-five miles in ditches and pipes.

At the Ophir mine laying the stone foundations for the new and powerful incline machinery is making steady and favorable progress.

GOOD HEALTH.

Necessity of Sleep.

There are thousands of busy people who die every year for want of sleep. Sleeplessness becomes a disease, and is the precursor of insanity. We speak of sleep as the image of death, and our waking hours as the image of life. Sleep is not like death; for it is the period in which the waste of the system ceases, or is reduced to its minimum. Sleep repairs the waste which waking hours have made. It rebuilds the system. The night is the repair-shop of the body. Every part of the system is silently overhauled, and all the organs, tissues, and substances are replenished. Waking consumes and exhausts; sleep replaces and repairs. A man who would be a good worker must be a good sleeper. A man has as much force in him as he has provided for in sleep. The quality of mental activity depends upon the quality of sleep. Men need, on an average, eight hours of sleep a day. A lymphatic temperament may require nine; a nervous temperament six or seven. A lymphatic man is sluggish, moves and sleeps slowly. But a nervous man acts quickly in everything. He does more in an hour than a sluggish man in two hours; and so in his sleep. Every man must sleep according to his temperament; but eight hours is the average. Whoever by work, pleasure, sorrow, or by any other cause, is regularly diminishing his sleep, is destroying his life. A man may hold out for a time, but the crash will come, and he will die. There is a great deal of intemperance besides that of tobacco, opium or brandy. Men are dissipated who overtax their systems all day, and undersleep every night. A man who dies of delirium tremens is no more a drunkard than a suicide, than the minister, the lawyer, the merchant, the editor, or the printer, that works excessively all day and sleeps but little all night.—*Henry Ward Beecher.*

HEALTH AND TALENT.—"It is no exaggeration to say that health is a large ingredient in what the world calls talent. A man without it may be a giant in intellect, but his deeds will be the deeds of a dwarf. On the contrary, let him have a quick circulation, a good digestion, the bulk, the sinews of a man, and the alacrity and unthinking confidence inspired by these, and, though having but a thimbleful of brains, he will either blunder upon success or set failures at defiance." So writes some one in the *Merchants' and Manufacturers' Bulletin*, but if he had a thimbleful of observation—he would have known that it takes a good deal more than a thimbleful of brains to drive such a carcass as he has described. Setting aside all questions of honesty and other qualities of a good character, the late James Fiske, Jr., was one of the most thoroughly energetic men this country has ever known, and after his death it was found that his brain weighed some four ounces more than the brain of Daniel Webster, and only about four ounces less than the brain of Cuvier, who is said to have had the largest brain ever weighed. It takes brains, as well as muscle, to drive the business of this busy world.

COUGHING AND COLDS.—The best method of easing a cough is to resist it with all the force of will possible, until this accumulation of phlegm becomes greater; then there is something to cough against, and it comes up very much easier and with half the coughing. A great deal of hacking and hemming and coughing in invalids is purely nervous, or the result of mere habit, as is shown by the frequency with which it occurs while the patient is thinking about it, and its comparative rarity when he is so much engaged that there is no time to think, or when the attention is impelled in another direction. Lemon juice, used as a gargle, is said by a French physician to be a specific against diphtheria and similar throat troubles, which he has successfully used for eighteen years. Another simple remedy, said to be quite as efficacious, is given as follows: Take onions, slices thin, and sprinkle loaf sugar thickly upon them; put in the oven and simmer until the juices are thoroughly mixed with the sugar. Give a teaspoonful four or five times a day.

TELEGRAPH MALADY.—Telegraph clerks will hear with alarm of telegraphic paralysis, a new malady reported by a French physician to the Académie des Sciences. An employee, who had been engaged in a telegraph office for nine years, found that he could not form clearly the letters U, represented by two dots and a stroke, I, by two dots, and S, by three dots. On trying to trace the letters his hand became stiff and cramped. He then endeavored to use his thumb alone, and this succeeded for two years, when his thumb was similarly attacked, and he subsequently tried the first and second fingers, but in two months these were also paralyzed. Finally, he had recourse to the wrist, which also shortly became disabled. He forced himself to use his hand, both and arm shook violently, and cerebral excitement ensued. It appears that this disorder is very common among telegraph clerks.

FOR FALLING HAIR.—Mrs. J. W. Cameron, of Vista, sends us the following recipe as something very effective for keeping the hair off, and to prevent it from falling out: 1 oz. nm camphor, ½ oz. pulverized borax; dissolve in 1 qt. boiling water.

EXTRACTING NEEDLES OR BITS OF IRON.—A simple and usually successful mode of extracting a needle or any piece of steel or iron broken off in the flesh is accomplished by the application of a simple pocket magnet. An acquaintance of ours had a little daughter who recently broke a needle off in her hand. A surgeon was called, who made several efforts to find the needle by probing and incision, but without success. After the surgeon had left, the mother conceived the idea of trying a magnet; one was procured, and after one or two applications of it, the broken fragment of needle was discovered attached to the magnet. This idea will be of especial utility to workers in iron. Machine shop surgery is not the most delicate or least painful, though men heroically undergo it rather than the loss of time due to an inflamed eye or festering finger. Iron filings have a way of imbedding themselves in the eyes, which defies almost every ordinary means of extraction. For their removal, a small blunt pointed bar of steel, well magnetized, will be found excellent, and we should recommend that workmen liable to such injuries keep such an instrument about them. It would be a good plan to insert such a bar in a penknife, in a manner similar to a blade.

EATING BEFORE RETIRING.—To take a hearty meal just before retiring, says a writer in *Scribner's*, is, of course, injurious, because it is very likely to disturb one's rest and produce nightmare. However, a little food at this time, if one is hungry, is decidedly beneficial; it prevents the gnawing of an empty stomach, with its attendant restlessness and unpleasant dreams, to say nothing of probable headache or of nervous or other derangements the next morning. One should no more lie down at night hungry than he should lie down after a very full dinner; the consequence of either being disturbing and harmful. A cracker or two, a bit of bread and butter, a cake, a little fruit—something to relieve the sense of vacuity, and so restore the tone of the system, is all that is necessary.

ALCOHOL VS. STRENGTH.—Training men for the prize ring, they are not allowed to touch spirits, tobacco or any other such stuff. Billiard players training for a match carefully avoid all such indulgences. When not training, these people are likely to indulge pretty freely in spirits and tobacco; but when seeking the highest health they are compelled to deny themselves. And yet we constantly hear the healthfulness of gin and the meerschaum seriously discussed. It is stated that no man that has graduated at the head of his class in Harvard College, within the last fifty-five years, has used spirits or tobacco in any form.

DISINFECTANT AND MOUTH-WASH.—A weak solution of permanganate of potash will destroy instantly any taint from discolored teeth or imperfectly cleaned plates, and should always be used to rinse spoons with in hot weather. It is cheap, satisfactory, almost tasteless, not poisonous, and quite free from smell. It may be satisfactory to some to know that this will remove the taint of smoking from the breath if used as a mouth-piece.

USEFUL INFORMATION.

Improvements in the Arts of Metallurgy.

It is well known that the difficulty of uniting iron to brass is created by the unequal rate of expansion in the two metals, which destroys the unity when the temperature is changed. To meet this difficulty, an English artisan has invented an alloy, the expansion of which by heat is claimed to be so similar to that of iron and steel that the surfaces may be regarded when joined, as permanently united for all practical purposes. It consists of three parts tin, thirty-nine and a half parts copper, seven and a half parts zinc.

The construction of bronzes has lately been much improved by the addition of a small amount of phosphorus. A special cause of the inferiority in bronze consists in the constant presence of traces of tin in the state of an oxide, which acts mechanically by separating the molecules of the composition, thus interposing a substance which in itself has no tenacity. Now, the addition of phosphorus is found to reduce this oxide, and renders the bronze much more perfect, improving its color, its tenacity, and its physical properties. Thus treated, the grain of the bronze, when fractured, resembles more that of steel, its elasticity is much augmented, and its resistance to pressure sometimes more than doubled.

TO TAKE OUT BRUISES AND TO REMOVE STAINS FROM FURNITURE.—To take out bruises, wet the part with warm water; double a piece of brown paper five or six times, soak it and lay it on the place; apply on that a hot iron till the moisture is evaporated; two or three applications will raise the dent or bruise level with the surface. If the bruise be small merely soak it with warm water and apply a red-hot iron very near the surface; keep it continually wet, and in a few minutes the bruise will disappear. To remove stains, wash the surface with stale beer or vinegar; the stains will be removed by rubbing them with a rag dipped in spirits of salt. Re-polish as you would new work. If the work be not stained, wash with clean spirits of turpentine and re-polish with furniture oil.

Economy in the Machine Shop.

In building machinery, no matter for what purpose it may be required, or to what uses applied, there is nothing in the experience of those who have devoted years to the business so prominent as their faith in good material. This faith never waxes; it grows steadily. This course of many an establishment is to be found in what is termed "cheap" material. Let any one contemplating an investment in a manufacturing business observe the advantages secured by the establishments that make it a point to employ the best material in the machinery, and contrast it with the result where the so-called "cheap" articles are used, and in setting out avail himself of the knowledge thus obtained, and he will have accomplished an immense step in advance; he will have reached a point that consumed years and many toilsome steps on the part of old manufacturers to achieve. There is no economy in substituting the cheap for the good. There is never anything gained by employing a cheap thing simply because it is cheap. For instance, never use brass in the erection of machinery when your judgment favors gun-metal (copper and tin). Whatever in your judgment is best, is the proper material.

Nothing is more common than to find brass substituted for gun-metal in heavy machinery. The result is that much vexation and trouble ensues. Never use wrought iron instead of steel, simply because it is more easily worked or cheaper than steel. Recently our attention was directed to an instance where a large lot of costly machinery was made and shipped a considerable distance, in which certain parts were made of steel and wrought iron, instead of wholly of steel. After running a short time, the entire establishment was forced to stop operations, when the proper material was placed where the judgment resulting from costly and vexatious experience required it. Of course the builder lost by the operation. This mistaken idea of economy frequently causes the annual stoppages of our large manufacturers, in order to make what are sometimes mis-called "repairs." If the rule were strictly followed, never to make of cast iron that which should be made of wrought iron, of wrought iron that which should be made of steel, of brass that which should be made of gun-metal, there would be less necessity for long stoppages.

Takes the question of foundations: Wooden foundations are no longer viewed with favor as a base for heavy machinery. The cost of removing machinery to replace the foundation is no inconsiderable item. Foundations of stone or something as durable, are growing into favor, because they outlast the heaviest machinery. Heavy screw boxes made of wrought iron are cheaper in the end than boxes made of metal. In fact, true economy always avails itself of the best material.—*Exchange.*

Paint as a Preservative.

Paint, in the view of utility, is employed as a protective covering to a body, against the injurious influences of the air, water and other destructive agencies. Wood and the common metals are especially attacked by oxygen, contained in our atmosphere, of which it constitutes about 21 per cent., being the 21-100th part of the whole atmosphere. It is also a component part of water, forming nearly 88-100ths of its whole weight. Although its presence is absolutely necessary to the continuance of animal life, yet metals exposed to the air are consumed by the oxygen as in a fire. This utility, therefore, of paint as a protector is so apparent that any study of its composition and properties, which will tend to improve it in any degree, is of great importance.

Paint is understood to be a mixture of a liquid and a solid, in powder. The desirable physical conditions of these are, that the liquid should have a certain amount of viscosity, in order to maintain the powder in suspension; and that the powder should be as fine as possible, and nearly of the same specific gravity as the liquid. Linseed oil is undoubtedly the best mixture for paints that are to be exposed to the weather. It absorbs oxygen and becomes solid and waterproof; and yet it always possesses some elasticity which prevents it from cracking. Theory, and the almost united voices of practical painters, after centuries of experience, have decided, that, in view of its inherent properties and its cost, nothing at present known can take its place. There may be special uses of paint, where some other article may be substituted with advantage, yet we cannot reasonably look beyond the class of substances known as drying oils for a substitute. Volatile oils, and such as resin oil, which oxidize into brittle resins, are altogether out of the question. Of the pigments used for preparing paint, we may mention lampblack, white lead, red lead, vermilion, verdigris, ochres, etc.

POLISHING VENEERS.—Get a little chromate of potash and put it in a 4-oz. bottle; add water. After cleaning off veneers, legs, etc., saturate a sponge with the above, and go over your work evenly. According to the strength, in a few minutes you may make lightest mahogany any color you require. When dry, polish. Corked up, it will keep any length of time, always ready for use, and you can repeat it either before or after oiling, if not dark enough. But if you get your work too dark, you will have a job to paper it off evenly, especially in turned work. It won't stain where there is polish or glue.

DOMESTIC ECONOMY.

The Art of Cooking—No. 1.

The science and art of cooking may be divided into a few principal parts; the rest is all fancy. These parts are baking, boiling, broiling, frying, roasting, seasoning, simmersing and stewing. Tasting is an adjunct to all.

BAKING.—In baking, as that the furnace or oven be properly heated; some dishes require more heat than others. Look at the object in process of baking from time to time, and especially at the beginning; turn it round, if necessary, in case it be heated more on one side than the other, to prevent burning. In baking meat and fish, besides keeping the bottom of the pan covered with broth or water, place a piece of buttered paper over the object in the pan. It not only prevents it from burning, but acts as a self-basting operation, and keeps the top moist and juicy. If the top of a cake bakes faster than the rest, place a piece of paper on it.

BOILING.—This is the most abused branch in cooking. We know that many good meaning housewives, and even professional cooks, boil things that ought to be prepared otherwise, with a view to economy; but a great many do it through laziness. Boiling requires as much care as any other branch, but they do not think so, and therefore indulge in it. Another abuse is to boil fast instead of slowly. Set a small ocean of water on a brisk fire and boil something in it as fast as you can; you make much steam but do not cook faster, the degree of heat being the same as if you were boiling slowly. If the object you boil, and especially boil fast, contains any flavor, you evaporate it, and cannot bring it back. Many things are spoiled or partly destroyed by boiling, such as meat, coffee, etc. Water that has been boiled is inferior for cooking purposes, its gases and alkali being evaporated.

BROILING.—Whatever you broil, grease the bars of the gridiron first. Broiling and roasting are the same thing; the object in process of cooking by either must be exposed to the heat on one side and the other side to the air. Bear in mind that no one can broil or roast in an oven, whatever be its construction, its process of heating, or its kind of heat. An object cooked in an oven is baked. It is better to broil before than over the fire. In broiling before the fire all the juices can be saved. In broiling by gas there is a great advantage. The meat is placed under the heat, and as the heat draws the juice of the meat, the consequence is that the juice being attracted upward it is retained in the meat. A gas broiler is a square flat drum, perforated on one side and placed over a frame. Broiling on live coals or on cinders without a gridiron is certainly not better than with one, as believed by many; on the contrary, besides not being very clean, it burns or chars part of the meat. That belief comes from the fact that when they partook of meat prepared that way, it was with a sauce that generally accompanies hunters, fishermen, etc., hunger, the most savory of all savory sauces.—*The Housekeeper.*

CLEANING SILK DRESSES.—Silk dresses may be cleaned by potato water in this way: Grate potatoes into clear, cold water—a large potato to every quart of water, of which five or six will do for a couple of dresses. If for very light silk, pare the potatoes, but in any case wash them clean. The pan of water must not be stirred in the least for forty-eight hours; then very slowly and steadily pour off the clear liquor, but not a particle of the sediment, into an open vessel, dip the pieces of silk into this liquid up and down a few times, without the least wringing them; then wipe them on a flat table with a clean towel, first one side then the other. It is good to hang each one as it is dipped upon a line, to allow the drops to drain off a little before wiping. Iron one way on the soiled sides.

RED MARKING INK FOR CLOTHING.—A red ink for marking clothes, which is not attacked by soap, alkalis, or acids, is prepared as follows: Enough finely pulverized cinnabar to form a moderately thick liquid is very intimately mixed with egg albumen previously diluted with an equal bulk of water, beaten to a froth, and filtered through fine lins. Marks formed on cloth with this liquid, by means of a quill, are fixed after they have become dry, by pressing the cloth on the other side with a hot iron. The ink will keep in well closed bottles for a long time without separation of the suspended cinnabar.

MUTTON STEW.—Take such scraps of mutton or lamb as are not fit for chops or cutlets. Just cover with water. Add a little onion and parsley, and season with salt and red and black pepper. Boil two eggs hard, or if making a good-sized stew use more. Mash or grate the yolks fine, and stir them into a tablespoonful of butter and the same amount of browned flour. Stir into the stew just before dishing. Let it boil up once after adding this, and serve as soon as it thickens.

COFFEE STARCH for black and dark brown calicoes, percale and muslin; also for grass clothes and Hollands. Mix two tablespoonsful of the best starch into a paste with cold water. Stir it into one pint of boiling coffee well settled. Boil ten minutes. Stir a few times with a spoon or wax candle. Strain through a cloth and use.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Rae's System of Amalgamation; Academy of Science, 329. Improved Amalgamator and Separator; Water Balance for Hoisting; Expedition to Southern California; Short Lectures on Patents; Post Pliocene Fossils, 336. The Glacial Period—Its Origin and Development; Hint on the Wachoe Process, 337. Notices of Recent Patents, 340.

ILLUSTRATIONS.—Rae's System of Amalgamation, 329-337. Striped Lead Map, 333. **SCIENTIFIC PROGRESS.**—The Transit and its Probable Results; What Cheap Electricity is Expected to do; Electricity—Interesting Observations; Curious Water Formation; Size of a Molecule; Curious Effect of Gas Flame; Curious Phenomenon; A New White Alloy; Ozone; An Earthquake Record; Force of the Wind, 331.

MECHANICAL PROGRESS.—Metallic Belts and Bend Saws; Internal Grooving in Steam Boilers; Progress of the Arts; Five Hundred Shots a Minute; Bessemer Steel Works in Sweden; An Improved Blower, 331.

MINING STOCK MARKET.—Sale at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 332.

MINING SUMMARY from the various counties in California and Nevada, 332-3.

POPULAR LECTURES.—Economy of the Vegetable Kingdom, 334.

GOOD HEALTH.—Necessity of Sleep; Coughing and Colds; Telegraph Malady; For Falling Hair; Extracting Needles or Bits of Iron; Eating Before Retiring; Alcohol vs. Strength; Disinfectant and Mouth Wash, 335.

USEFUL INFORMATION.—Improvements in the Arts of Metallurgy; Economy in the Machine Shop; Paint as a Preservative; To Take out Bruises and Remove Stains from Furniture; Polishing Veneers, 335.

DOMESTIC ECONOMY.—The Art of Cooking—No. 1; Cleaning Silk Dresses; Red Marking Ink for Clothing; Mutton Stew, 335.

MISCELLANEOUS.—Home Industries; "Petting Out"—California Mines; Hydraulic Elevators; Hurdy Gurdy; Smiles; Senseless Opposition to Scientific Exploration; Discovery of Valuable Iron Ore in Norway; Dangerous Sophistication of Silk; Fast Railroad Time; Pre-historic Relics; Eruption of Sulphuric Acid, 330. Mines Abandoned in Mexico; Fire Clay, 334.

Improved Amalgamator and Separator.

John Rutherford, of this city, has recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, an amalgamator and separator for precious metals, but more especially adapted for saving gold from auriferous and magnetic sands, and gold, silver and amalgam from the tailings or pulp of quartz mills. It consists of a series of steps or levels one below the other in an inclined frame, and the pulp or sand is made to pass from the upper level upon which it is fed, alternately through a series of screens which are provided with amalgamated balls or cylinders of copper or other metal, and from these screens over amalgamated plates until the mass reaches the lower end.

An alternate shaking and convulsive movement is given to the frame holding these screens and plates, by which the balls or cylinders are kept in motion all the time, and being amalgamated a thorough and complete separation of the precious metals is accomplished.

The inventor finds that the use of amalgamated balls in constant motion upon the surface below serves to stir up the sand and gold, and to wear "rusty gold" bright, so that it will all be amalgamated, while a certain electric action, consequent upon the use of the copper balls and iron screens will assist in saving the gold and any amalgam or quicksilver from the pulp of mills. It is, however, in working the magnetic or black gold sands that the invention is chiefly valuable, as those sands have already been naturally subjected to the action of water to such an extent that there is no appreciable difference in the specific gravities of the different constituents, and it is almost impossible to save the gold by any means known at present. By this machine such a thorough rubbing and separation of particles takes place that all the gold is brought into contact with quicksilver under such circumstances that it will be almost certain to amalgamate.

Water Balance for Hoisting.

In many of the open works on the northern side of the great coal basin of South Wales, water balance machines are used for hoisting purposes, for mines of no very great depth. In a district where there is a good supply of water and free drainage by means of adits, the system is economical and may be recommended. Sometimes water balance machines are used when there is no drainage, the water being pumped up from the bottom by an engine, but this is not an economical arrangement. In some cases the machines are placed at different levels, so that the same water is used five or six times over as many successive lifts.

The car, holding from one to two thousand pounds of ore or water is placed in a cage over an empty water bucket, and the empty car on a similar bucket on the top. Water is then made to flow into the upper bucket until its weight is great enough to make it descend, in this manner raising the loaded car on the other end of the rope. The buckets are made of half inch boiler plate, circular in form, and some hold more than two tons of water. The landing chain is balanced by a chain which hangs below each bucket, and guide chains are used to keep the buckets from striking each other when the shaft is not divided in two departments. A speed of 300 to 400 feet per minute is easily attained by the machine, and the total cost for raising stuff—in Wales—is one and one-half pence per ton per fifty fathoms. For great depths the weight of the machinery becomes so great that the economy disappears. Somewhat similar machines are used in some of the iron mines in both Lancashire and Cumberland.

Expeditions to Southern California.

It is understood that a portion of one division of Lieut. Wheeler's expedition will operate this year in Southern California, including portions of the coast range and the Sierra Nevada, extending westward as far as Death valley. In addition to general geographical pursuits by Lieut. Wheeler during the last five years, he has been directed to make a special examination and survey with a view to determining the practicability of diverting the water of the Colorado of the West for irrigating and other purposes. He will also send a small party to co-operate with a similar one sent out by the Smithsonian Institute to make archaeological researches and collections in Santa Catalina islands.

A party will also leave the University of California about the tenth of June on an exploring expedition to Yosemite, Death valley, Mt. Whitney, etc. Prof. Joseph Le Conte will head the party, which will consist of five or six of the Professors and students. The party will go on horseback, and will be provided with arms, pack horses and complete outfits. The collections made in the different departments will be sent to the University museum. The interior of the State, and especially the higher mountainous regions, possesses features of great interest to the scientific student. To geologists, perhaps no place in the United States offers greater inducements for research and examinations; and to collectors of objects of scientific interest there is a magnificent field open.

We are certain that many interesting facts will be developed by the parties about to start out, and trust that every facility will be offered to them by the people among whom they sojourn.

THE MARIPOSA COMPANY'S TROUBLES.—A history of the Mariposa company's troubles was related in the Superior Court in the opening by James H. Choate, in the suit brought by the secretary of the company against Eugene Kelly. When the old Mariposa company dissolved, the property went into the hands of Mark Brummagin and other trustees, who were to work it up in the best way they could, and in so endeavoring they issued certificates, on which speculations were made. At this time Kelly says the company became indebted to him for some \$300,000 advanced, while plaintiff holds that the whole affair was privately arranged between Kelly and Brummagin, and the company cannot be held responsible for anything due Kelly by the trustees in his individual capacity. The trustees ordered the property to be sold for taxes, and an agreement was made that Kelly should buy in the property. Kelly now claims that the expenses connected with retaining possession of the property from squatters, and the sale purchases, amounted to \$126,000. Pending the settlement of the question, a company has been formed in California with the same name, and a deed has been made of the New Jersey company's stock to it. Kelly, in a suit in the Supreme Court, has enjoined any further proceedings to consummate the transfer, and has had a receiver appointed of the property in this.

STEAMER JAMES M. DONAHUE.—The trial trip of this new steamer, built in San Francisco, for the San Francisco and North Pacific railroad company, takes place May 22d. We shall have more to say of it hereafter.

A NUMBER of parties have arrived at Cheyenne who intend going to the Black hills as soon as the Government permits.

Short Lectures on Patents.

No. 5.—By JNO. L. BOONE, of Dewey & Co's MINING AND SCIENTIFIC PRESS Patent Agency.

The Specification.

In order to obtain a patent the inventor is required to file a description of his invention, and this description is called the specification. Upon the preparation of this document depends the strength and validity of the patent when it is issued. The invention must not only be described, but it must be described intelligibly so that others can understand it. Its object is not only to define what the inventor has discovered and accomplished in order to protect him during the existence of the patent, but also to teach the public how to construct and use the invention successfully when the patent expires. Everything that is necessary to the successful operation of the invention must be disclosed, no secrets are tolerated. If it can be shown that the inventor withheld an important or necessary element or part of the invention the patent can be defeated. The specification is the foundation upon which the patent is based. If it is weak the patent can be easily overthrown. It is the inventor's statement of his invention. He describes it in his own words, and the officers of the Patent Office have no right to change its meaning or phraseology. They may reject it for want of formality, or because its construction is such that it is liable to deceive or mislead the public, and they will require the inventor to amend and correct it before they will allow it, but the manner of describing the invention and the phraseology are left to the inventor or his agent.

A rambling, incoherent specification will invariably defeat the patent, and even an erroneous statement if it effects the essence of the invention, will defeat it. There is something pleasing and satisfactory in a crisp and plainly worded specification. It gives the reader a more exalted idea of the invention, and is evidence that the invention was not guessed at or only half digested before the patent was applied for. It presents no cause for quibbling, and gives no occasion for explanations. A large proportion of the trouble and annoyance to which inventors are subjected by infringers and improvers is occasioned by imperfectly prepared specifications.

A patent does not necessarily cover all that is described in the specification. If the invention is an improvement upon an old machine it is generally necessary to describe either the whole or a part of the old machine, in order to show the connection and operation of the invented part. Whatever the specification may describe, the patent only covers what is stated in the claims. The specification is only a description by which the claims are to be interpreted and defined. It is often the case that patents are bought and sold on the strength of what is described in the specification, without reference to what is claimed. The person who thus purchases a patent is almost sure to get into trouble.

The Claims.

After describing his invention the inventor sets forth what he claims and desires to secure by the patent. The claims cover only that portion of what is described in the specification that is new, and the patent covers only what is claimed, so that if we would learn what the patent secures to the inventor we must examine the claims, and to interpret them we must refer to the specification. To properly set forth the claims to an invention, so that the inventor will be fully protected, requires the greatest skill of the patent solicitor. If they are improperly stated the patent is inoperative.

A claim is either broadly for a new device or for a combination of several devices which act together to produce a new result. In the first instance the device which is claimed broadly must be new and it must produce an independent result or be a complete thing without the assistance of the other parts of mechanism. In the latter case the parts combined must act together to produce a result.

Some inventors entertain the opinion that a combination claim is of no value. This is a false idea. A combination claim is just as strong in law as any other if it is properly constructed. Where the combination is legitimate and the parts absolutely necessary to produce a result a combination claim is just as good, and just as strong as a claim for each individual part, and in most cases it is the only way that the inventor can be protected. The great difficulty is to correctly state the combination, so that nothing that is useless or not necessary is incorporated in it, and to do this not only requires legal but mechanical skill. One machine may contain several legitimate combinations of parts, each of which may be claimed, and it often requires the nicest discrimination and the profoundest patent judgment to combine and arrange these parts properly in the claims. By far the greatest number of patents issued from the Patent Office are for the combination of two or more mechanical parts, and in patents for improvements on existing machines this is almost always the case, because the new is combined with the old. A combination claim must cover those parts which are necessarily parts of the same movement, or in other words, which co-act to produce a result. To combine the hands of a watch with a watch chain, even if the chain is new in its construction, would not be a legitimate claim, because the one is entirely

separate and distinct from the other, and no connection or co-action exists between them. Each performs a separate duty and can in no way aid the other; but to combine the hands with the movement or internal mechanism of the watch would be legitimate if the mechanism made the hands perform a new duty; but there must be some new action between the parts to render even this combination patentable. In a combination claim nothing short of all the parts which act together to produce a result is legitimate. If a device or single piece of mechanism is new entirely and complete in itself, independent of the surrounding devices or parts, it can be claimed separately, but if it is only new in part, the new must be claimed in combination with the old, because it requires the whole to perform a duty.

A claim cannot be for a result, nor for a mechanical principle; but when an inventor has discovered a new result or principle, together with the machinery which produces it, and secures a patent for this machine or device, he is entitled to cover all equivalents, which is virtually covering the principle. All claims cover equivalents without the words "or their equivalents" being stated. The examiners in the Patent Office will even reject a claim which contains these words, because the law provides for covering equivalents, and their presence in a claim would be useless.

The wording of a claim is all-important. Many patentees are content if the device or part which they think most, is mentioned anywhere in the claims, whether it be combined with one or a dozen other parts, and often claims are so blindly worded that it takes a keen patent lawyer to find out the patented point, if, indeed, the claims cover any point at all. There is no remedy for this as long as inventors will persist in placing their applications in the hands of cheap patent agents. Fortunately the law has provided a remedy in case the patent has not been taken out properly, and this remedy will be the subject of my next lecture.

Post Pliocene Fossils.

Rev. Stephen Bowers, of Santa Barbara, has collected the following post pliocene fossils near that city:

Amphissa corrugata, *Amycla tuberosa*, *Amycla gausapata*, *Acmaea spectrum*, *Barnacle*, *Barnacle attachment*, *Bithium quadrifidulum*, *Carochardone rectus* (shark's tooth); *Cariophyllia*, *Cancellaria gracilior*, *Calliostoma canaliculatum*, *Cancer* (crab's fingers), *Cerithiopsis* —? *Chama eclogra*, *Chione fluctifraga* (?) *Chrysodomus tabulatus*, *Chione succinea*, *Chrysodomus dirus*, *Chrysodomus byratus*, *Chlorostoma aureolinum*, *Calliostoma costatum*, *Cardium corbis*, *Conus Californicus*, *Clathurella Conradiana*, *Crepidula adunca*, *Crepidula excavata*, *Crepidula navicelliformis*, *Cryptomya Californica*, *Cumingia Californica*, *Dentalium hexagonum*, *Dentalium Indianorum*, *Diala acuta*, *Drillia inermis*, *Drillia meisa*, *Drillia moesia*, *Drillia torosa*, *Echinus* —? *Erato columbella*, *Eubina micaris*, *Fusus ambustus*, *Fissurella volcano*, *Galerus contortus* (?) *Glyptis aspera*, *Glycimeris tenera* (?) *Hinnites giganteus*, *Hippocypris cranioides*, *Hippocypris* —? *Ichnochelone Magdalensis*, *Jamburella*, *Lacuna solidula*, *Lacsea rubra*, *Lazaria subquadrata*, *Leda* —? *Leptothyra sanguinea*, *Leptothyra bacula*, *Leptothyra acuticostata*, *Liocardium substriatum*, *Lucina* —? *Lucina Californica*, *Lumata Lewisii*, *Macoma edulis*, *Macoma inquinata*, *Macoma nasuta*, *Margarita pupilla*, *Martesia intercalata*, *Mangelia*, (two species), *Mitra maura*, *Mitromorpha aspera*, *Modiola capax*, *Muricea Barbarensis*, *Mytilus Californianus*, *Nassa Cooperi*, *Nassa fossata*, *Nassa perpinguis*, *Neverita Reclusiana*, *Nitidella crysoloides*, *Nulipora* —? *Ocenebra aspera*, *Ocenebra lurida*, *Ocenebra interfossa*, *Ocenebra* —? *Olivella biplicata*, *Opalia borealis*, *Ostrea conchaphila* var. *expansa*, *Ostrea Taylorana*, *Pachypoma gibberosum*, *Pecten cerroensis* (?) *Pecten hastatus* (?) *Pecten Islandicus*, *Pecten latirhinus*, *Pecten moniliformis*, *Pholidadia ovoidea*, *Parapholas Californica*, *Placunomia macrochisma*, *Pleurotoma perversa*, *Phorcus pulgino*, *Porites*, *Polyspora*, *Pomaxia undosus*, *Priene* —? *Priene Oregonensis*, *Psephus Lordi*, *Psephus jantella*, *Pisania fortis*, *Pteronotus festinus*, *Purpura* —? *Purpura crispata*, *Puncturella cucullata*, *Rupellaria lamellifera*, *Saxidomus* —? *Saxidomus Nuttalli*, *Scalaria Indianorum*, *Scalaria Indianorum* var. *tinda*, *Scurria mitra*, *Schizothaerus Nuttalli*, *Septifer bifurcatus*, *Serpulorbis squamigerous*, *Solen* —? *Solecurtus Californianus*, *Subtricola alba*, *Surcula "Carpenteriana"*, *Tapes staminea*, *Tapes diversa*, *Tornatina cerealis*, *Tornatina cucullata*, *Trophon Orpheus* (?) *Trophon triangularis*, *Turritella Cooperia*, *Venericardia borealis*, *Waldheimia* —? *Zirphaea crispata* (?)

The above list comprises one hundred and thirty-three species and varieties. Mr. Bowers has a number not yet identified, and he is continually adding others, and hopes soon to swell the list to two hundred, or more, species.

REVISED STATUTES.—Walter A. Skidmore, of this city, has issued a work containing the revised statutes of the United States relating to mineral lands, with the circular instructions of the general land office, a digest of the decisions of the Department of the Interior, together with an appendix of special statutes relating to mining, with a collection of forms and a very complete index. The publication contains a table of reference showing the corresponding sections of the mining laws of 1866, 1870 and 1872, and the revised statutes. Published by Sumner, Whitney & Co., San Francisco.

The Glacial Period—Its Origin and Development.

At the last meeting of the California Academy of Sciences, a paper was submitted by J. E. Clayton, of Salt Lake City, on the "Glacial Period—Its Origin and Development." We give below an abstract of this interesting paper furnished us by the Secretary. Mr. Clayton, who has been a careful student of the glacial phenomena presented on the western slope of North America, discovered, in 1860, the marking and terminal moraines of the glacial system of the Sierra Nevada Mountains, at the head waters of the Merced and Tuolumne rivers.

Many theories have been advanced to account for the sudden change of climates of our planet at the close of the Tertiary age, from temperate and tropical heat to that of Arctic cold. Many such theories are based on assumptions of conditions and causes, untenable by logical deductions from general laws governing the progressive development of our planet.

Mr. Clayton then reviewed some of the theories of eminent scientists attempting to account for the great climatic changes at the close of the Tertiary period.

First Theory.

The writer cited the theory of a great upheaval of land in the Northern Hemisphere, by which the currents of the ocean and atmosphere were greatly changed, and consequent changes of temperature resulted.

While he admitted a possible modifying influence from this cause, he argued that as the thermal effect of the sun's rays upon the land surface is much greater than upon water, and the average land altitude of the North American continent would not exceed 2,000 feet, such a change, instead of precipitating a glacial period, would, in all probability cause an increase of atmospheric temperature.

As an elevation of the continent would largely increase the land area, and consequently the thermal effect of the sun, such a change would not supply the conditions for a continental glacial system. Hence he argued the elevation of land surfaces in the Northern Hemisphere was not a primary or adequate cause of the ice period.

Second Theory.

Some investigators argue a change in the relative position of the earth's poles, thus changing frozen zones into temperate and tropical latitudes. He argued that a self-balanced rotating globe could not change the position of its mass without changing the line of its rotation; and unless the cause of such a change could be shown, which had never yet been done, the theory must be untenable.

If the general proposition is true that the earth, originally incandescent, has been slowly cooling by radiation, the conditions for even tropical life must have begun at the pole and progressed toward the tropical zones in harmony with the cooling climate. Violent disturbances of the earth's level have taken place; without these, the changes of life creeping toward the equator as the earth's crust thickened, and consequently cooled, would have been slow and almost imperceptible. He therefore rejected the theory of a change of poles as incapable of proof.

Third Theory.

Some think the solar system, sweeping through space, may have encountered frigid zones, capable of reducing, by contact, the earth's atmospheric temperature sufficiently to cause an ice period.

If this were true, the waters of the globe would have frozen universally over its whole surface, and the extinction of life would have been a slow starving or "freezing out" process, incapable of accounting for the facts of glacial times. He therefore concluded that cosmic influences had no direct agency in producing the glacial epoch at the close of the Tertiary age.

Necessary Conditions for a Glacial Period.

Facts point to the geological disturbances and volcanic eruptions, which occurred at the close of the Tertiary age, acting upon the upper currents of returning trade winds as the only causes sufficient to produce the glacial phenomena as now indicated by geology.

These conditions were first a folding and dislocating of the earth's great longitudinal lines, north and south, along the western borders of one or more continents; followed by great outflows of lava and great issues of interior heat along such lines of fracture; then the local vaporization of the surface waters by contact with lava overflows; the ascent of vapors to a height sufficient to penetrate the return trade winds, when blowing as an upper current of the atmosphere, together with the general depression of the ocean beds and corresponding elevation of continents and development of great mountain chains.

That such conditions and facts did occur at the close of the Tertiary age substantially in the order named, is generally admitted by practical geologists. He argued that these conditions, in conjunction with the upper currents of the atmosphere, were ample, and would of necessity produce the glacial epoch.

Continents of the Tertiary Age.

In the beginning of this age the largest areas

of continents consisted of low undulating surfaces slightly above the ocean level. Large districts were covered by fresh water lakes and inland seas, whose ancient beds alternately present forms of life peculiar to marine, brackish and fresh water, showing that slight oscillations of the earth's surface were sufficient to cause interior continental basins to be filled with salt water. Great changes of level were successively produced in this age, over large areas, until the continents became mostly dry land. In later Tertiary periods marine deposits were gradually confined to the low borders of continents, and interior basins were filled exclusively with fresh water drainage.

The Climate in the Tertiary Age

Fluctuated from a tropical warmth, at first universal, to a temperate, and later to an Arctic cold, in higher altitudes, where great mountain chains were elevated. At the close of the Ter-

the greatest lava outflows being along the lower flanks and plateaux of continents.

The lecturer then reviewed the wind currents, demonstrating the freezing of vapors and their distribution over portions of continents remote from active igneous disturbances. If the earth was a perfectly smooth sphere, atmospheric currents would move with mathematical accuracy. Their thermal modifications were then explained, especially along the west coast of North America, where the polar current swings far westward over the Pacific, and dry winds sweep over it in a northeasterly direction.

At the close of the Tertiary age, the western slope of this continent was the principal scene of volcanic action. Districts as large as some of the smaller States were buried to unknown depths with lava and ash, while rivers and lakes were deflected and swept out of existence.

Mr. Clayton's Theory.

The vapors of rivers turned upon hot lava beds

Ground Plan of Rae's Amalgamating Mill.

tiary age the disturbances of the solid crust of the earth were enormous. Great mountain chains were elevated, accompanied by a corresponding depression of ocean beds, thus increasing the land and reducing the ocean to narrow limits. These occurred mainly by sudden convulsions and readjustments of the crust.

Continued radiation of heat from the fluid nucleus of the globe caused its continued shrinkage. The consolidated crust conformed to its continued shrinkage by corrugations and oscillations of level, until the lateral pressure of the crust became so great as to culminate in a series of dislocations and uplifts over all the continents of the globe, and resulting in the settling down of the broken, folded and dislocated crust with nearly its full weight upon the molten interior mass.

This gravitating pressure would cause outflows of lava through ruptured crevices, until the fluid and solid portions of the globe were balanced according to their relative weight and density, as water ascends in fissures of broken ice to a point of equal weight. The greatest outflow of lava occurred where the greatest downward folding took place, and is shown by islands in oceans being of volcanic origin, and

Elevation or Front View of Rae's Amalgamating Mill.

overwhelmed and buried by sudden falls of snow, consequent upon the overwhelming effects of a great geological change. Buried mestodous were found with stomachs full of food, showing the catastrophe to have been sudden.

Notwithstanding altitudes of the Pacific portion of the United States were greater, no traces of a continental system of glaciers are here visible, and all known glaciers are simply local, clustering around the polar sides of higher peaks. The basins of the western volcanic region were filled with a hot sea, hissing steam and volcanic products.

In the Sierra Nevada, the ancient river system has been completely changed by the later lava flows, so notable in Tuolumne, Sierra and Plumas counties.

Some discussion on this subject ensued between Dr. Blake and Mr. R. E. C. Stearns, and the question will probably come up again at a future meeting.

Hints on the Washoe Process.

(Continued from last week.)

The Crushing in the Battery.

Here might come a discussion as to the relative advantages of self-feeding and feeding by hand. Eventually I believe that automatic feeding will be universally adopted, especially for ore broken to a uniformly small size. Even under present circumstances the automatic feed is more economical than to have a man feeding who is careless, lazy, or inexperienced. For a good battery-feeder give me a small, intelligent, active, and wiry man; a tall or stout man cannot stand the jar of the battery constantly and do good work. A tough man can endure feeding twenty stamps for twelve hours. If ten stamps or less are to be supplied with ore, self-feeding is more economical than feeding by hand as performed by ordinary workmen; but if the mill is pressed with work, and the pans are of sufficient capacity to crowd the battery, the self-feeding apparatus is not so good as a man active, faithful, and skillful. Even if he must be paid five dollars a day, he will more than earn his wages by the increased production of the whole mill. Low feeding is the best; let iron almost wear on iron. The skillful workman will feed low and uniformly, and not by sight, but by the sound of each stamp. Under this system a stem may break occasionally, but it does not take long to put in another. The broken stems can be repaired by cutting off above the break and welding on a piece of a bar of rolled iron, which is subsequently turned off in a lathe. Even if three stems out of twenty are broken every month, the cost of repairing, etc., amounts to little compared with the increased production obtained by low feeding.

The stem almost invariably breaks in one place, namely, where it comes out of the stamp socket or boss. We avoid this evil partially by boring out the socket and increasing the size of the stem where it enters the socket. The broken surface of the wrought iron stem shows the iron to be thoroughly crystallized; its fibrous condition having been destroyed by the constant jar. A bar of round iron should be always on hand with which to repair broken stems.

As regards the weight and speed of the battery, my experience favors light stamps and the utmost speed. The Owyhee mill battery, 650-pound stamps, with eight and a half inches drop, (running to ten inches before re-setting,) was run at a speed of ninety-three drops a minute, the cams having been cut off so as to have short cams. Such a speed gives no time for the stem to settle in the sand; and as long as bolts are kept tight, nuts secure, and guides snug, no serious breakage need be apprehended. On ordinary ores the consumption of iron per ton, including the old iron thrown away, is about two pounds.

As regards the supply of water for the battery, there should be as much fall as possible from the battery to the tanks, so that the conducting troughs will keep clear and not choke up; they will then require no excess of water. The supply to the battery must vary according to the clay in the ore. Use as little water as practicable, consistent with keeping the screens perfectly clear. The more clay, the more water needed; the more clay, the greater necessity for careful low feeding, in order to avoid the choking up of the mortar. If too much water is used, to remedy the effect of careless folding, an unnecessarily large amount of slimes are carried off out of the mill in the waste water from the battery and tanks. To avoid the loss of slimes, it is well to use rather coarse screens, say No. 4 punched Russia iron, especially in clayey or slimy ores, so as not to puddle or churn the ores in the mortar more than necessary. This is particularly to be looked after when the ore is largely true silver ore, or the gold very fine. As regards getting the battery, it is, in my judgment, preferable to give the central stamp of the five in each mortar the most drop; those adjacent on each side one-fourth inch less, and the outside ones one inch less still. But some millmen prefer an even set.

Many persons advocate amalgamation in the battery, in order to catch part of the gold and native silver in ores containing, in addition to these metals, silver sulphuret, chloride, etc., or gold coated with oxide of iron, etc., and, therefore, requiring subsequent reduction and grinding in the pans. But there is a strong objection to amalgamation in the battery. The amalgam thus formed is mostly a gold amalgam, and hence it is worth much more than the ordinary amalgam of a silver mill, and of this the workmen are all aware. It is, therefore, an additional temptation to stealing. The only benefit to be claimed for it is the possible catching of some of the gold otherwise floating away in the water and catching in the slimes. It will be found, however, that this amount of gold is very small. By determining the proportion in weight of battery slimes, that is, the fine, clayey material carried away in the waste water from the tanks and battery, which has never been in the pans, and by ascertaining the value of the slimes in gold proportional to the value of the ore in gold, it will be found that, as a rule, the entire loss in gold in the slimes is not over one per cent. of the entire amount of the gold in the ore.

Epilepsy or Fits.

A sure cure for this distressing complaint is now
made known in a treatise (of 48 octavo pages) on For-
eign and Native Herbal Preparations, published by Dr.
O. Phelps Brown. The prescription was discovered by
him in such a providential manner that he cannot con-
scientiously refuse to make it known, as it has cured
everybody who has used it for fits, never having failed
in a single case. The ingredients may be obtained
from any druggist. A copy sent free to all applicants
by mail. Address, Dr. O. PHELPS BROWN, 21 Grand

LOOK TO YOUR INTEREST!

MANUFACTURED BY THE

PACIFIC RUBBER PAINT
COMPANY.For many years chemists and others have experi-
mented in mixing India Rubber with Oil, Lead, etc.,
in order to produce a perfectly

WATER-PROOF PAINT,

And at last successful in their effort, have formed a
chemical combination of Rubber with oil paints,
which when applied becomes hard and elastic enough
not to crack or peel, from the action of the atmosphere,
with a gloss equal to work finished with varnish. The

Pacific Rubber Paint Company,

Of San Francisco, California, together with the RUB-
BER PAINT COMPANY, of Cleveland, Ohio, own all the
patents covering perfect combinations like the
above, which is known and sold by them as "Rubber
Paint."The great demand for the Rubber Paint induced this
Company to purchase of the Cleveland, Ohio, and New
York Rubber Paint Company, the patents for this
coat, and are now manufacturing this paint in all col-
ors, in large quantities, and have put the price below
the best lead and oil paints. The Rubber Paint is
prepared in Pure White, in all Cottage and other
colors, comprising any number of different shades and
put up ready for use, being a great advantage, as it can
be spread by any one.It Flows From the Brush Freely, Works
Easily, and Settles Promptly. It is avail-
able for all kinds of Painting,
And may be used with equal advantage on iron, stone,
wood, brick, or plaster.The Rubber Paint will cover more surface, cover it
better, and last much longer than Lead and Oil. Two
coats of the Rubber Paint is better than three coats of
Ordinary Paint.

SAN JOSE, CAL., March 20, 1875.

PACIFIC RUBBER PAINT CO., San Francisco.—Gentle-
men:—I have used and sold the Rubber Paint in this
city during the last four years. We have about one
hundred buildings painted with the Rubber Paint.
Among the prominent ones are the State Normal School,
Gates Institute, City Market, the residences of Josiah
Belden, J. W. Hinds, President Gold Note Bank, J. R.
Arguello, Santa Clara, etc. It has never failed to give
satisfaction, with a test of from one to four years, so
that its durability has been well tested. My sales last
year were nearly five thousand gallons.

Truly Yours, AMASA EATON.

Ayer's Hair Vigor

RESTORING GRAY HAIR
TO ITS NATURAL VITALITY AND COLOR.Advancing years, sick-
ness, care, disappoint-
ment, and hereditary
predisposition, all turn
the hair gray, and either
of them incline to shed
prematurely.Ayer's Hair Vigor, by
long and extensive use,
has proven that it stops
the falling of the hair
immediately, often re-
news the growth, and always surely restores its color,
when faded or gray. It stimulates the nutritive organs
to healthy activity, and preserves both the hair and its
beauty. Thus brashy, weak or, sickly hair becomes
glossy, pliable and strengthened; lost hair regrows with
lively expression; falling hair is checked and stablished;
thin hair thickens; and faded or gray hair resumes their
original color. Its operation is sure and harmless. It
cures dandruff, heals all humors, and keeps the scalp
cool, clean and soft—under which condition, diseases
of the scalp are impossible.As a dressing for ladies' hair, the Vigor is praised for
its grateful and agreeable perfume, and valued for the
soft luster and richness of tone it imparts.

JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

IMPROVED GAS METER.—Jacob Radston, San Francisco. This invention relates to certain improvements in dry gas meters, and consists first in a novel construction and arrangement of the inlet and outlet pipes, so that the pipes may be put on or repaired with much less trouble and expense than hitherto. The invention further consists in passing the operating rods up through the pipes instead of through separate stuffing boxes, and in a novel device for connecting the diaphragms with the links of the operating rods, so that the connections are easily renewed, and the motion of the diaphragms made adjustable. By means of suitable passages, the interior and exterior chambers of any meter are so connected with a single discharge, that accumulation of liquid in either or both chambers can be at any time drawn off. By means of a simple device the inventor is enabled to renew the glass in front of the indicators at any time, and the whole apparatus of a three diaphragm meter is fitted into a square outer case, which is much more convenient than a round or other shaped case.

TAP AND FAUCET.—Amos C. Springer, San Francisco. This patent relates to certain improvements in that class of devices for drawing liquids, which consist of a tap to be permanently fitted into the vessel, and a removable cock or faucet, and it is of a more special value for beer barrels and for the gauge cocks of steam engines, and containing vessels which have an interior pressure. It consists first of a hollow cylindrical tube, which is permanently fixed in the barrel or other vessel, and is provided at its inner end with a hollow plug, having two or more screw threads upon the outside, and a soft metal packing upon a shoulder at the inner end, by which it is made tight. Combined with this portion is a cock or faucet, which has a slot at its inner end to fit over a corresponding projection upon the plug. A rubber packing ring surrounds the stem of this faucet and fits closely the smooth interior of the stationary tube, so that when a half turn is given the faucet to screw the plug back, the liquid can escape. A simple nut surrounds the tube of the faucet, and by screwing it into the tube, connects the whole to either. By the peculiar construction of this device the inventor claims that he secures a perfect working tap and faucet, and it will not be possible for it to leak, as most devices of this kind do before being screwed down to a bearing. It is also equally available for a gauge cock for boilers, and the cocks can be renewed whenever necessary, by simply screwing the plug down tight and removing the cock. As the plug turns out instead of into the vessel, it can be easily renewed to clean the vessel, and is not likely to become clogged with sediment.

AUTOMATIC RAILROAD SIGNALING DEVICE.—James Gordon, San Francisco. This invention is an improved device which is intended to signal the approach of trains upon railroad lines, and it consists in the use of a series of tanks filled with water, and having floats which will operate by means of air which is compressed or caused to move in pipes connecting the point where the train may be with the signal station. A train passing the point where the vessel holding the liquid is located will depress a lever and this will raise a gasometer, drawing air into an air chamber which is placed in the center of the tank, by means of metallic valves. As soon as the train has passed, the weight of the gasometer will press upon the body of air just admitted, and this will drive the air out through a pipe leading from the air chamber to another air chamber in the signaling apparatus, and communicate its pressure throughout the whole length of the pipe. A suitable device is used to serve as a check and prevent the air from flowing back when the gasometer is lifted and the valves opened. The pressure from the pipe leading from the air chamber is communicated to another vessel and then acts on a second gasometer, and will raise it together with any attached signal, the operation being very delicate and instantaneous. A certain amount of pressure is preserved so as to balance the signal and thus hold it in readiness to be acted upon by the slightest additional pressure. A valve in the pneumatic bottle allows the air to escape from the vessel so that the signal will gradually descend after the train has passed, and by regulating the size of the escape orifice the length of time which the signal occupies in descending can be controlled.

It was the intention of the officers of the Virginia and Truckee railroad to put two hundred white men to work Monday, on the switch that is to run by the new shaft of the Caledonia mine, provided they could employ them at \$2.50 per day. All the unemployed men thought the rates too low, and refused to go to work. The work will not be prosecuted at present.

THE STICKEN MINES.—The Sticken river is full of drift ice, but still closed for navigation. There are more miners and traders in Carlsbad than any previous year, and all are confident of big pay.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., May 18, 1875.

FOR WEEK ENDING MAY 4, 1875.

MAIL BAG FASTENING.—Jes. C. Franklin, Lena, Oregon.

OVERALLS.—Samuel R. Krouse, S. F., Cal.

NEWSPAPER FILE.—Franklin B. Alderson, San Jose, Cal.

CAR COUPLING.—Adolph V. Anderson, Virginia City, Nev.

STEAM PLOW.—Duncan Beaumont, Sacramento, Cal.

REFINING BASE METAL BULLION.—Frederick H. Bousfield, S. F., Cal.

SPRING BED BOTTOM.—Augustus M. Dennen and Cassy Newhouse, Stockton, Cal.

ENDLESS WIRE WAYS.—Andrew S. Hallidie, S. F., Cal.

VENTILATING MINES.—Levi J. Henry, S. F., Cal.

AUTOMATIC AIR BLAST FOR GAS MACHINES.—Robert Newton, S. F., Cal.

SHOE FASTENING.—Theophilus Tucker, Oakland, Cal.

RE-ISSUES.

STRAW-FEEDING ATTACHMENT FOR FURNACES.—David Morey, Watsonville, Cal.

STEAM BOILER.—Harvey W. Rice, Haywood, Cal.

—The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. Note.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

The Cuban insurgents are destroying the sugar plantations in most of the districts of that unhappy country. The entire number of estates destroyed up to about the middle of April is reported at 100, valued at \$7,200,000, but worth, previous to the war, \$25,000,000.

In a recent article describing Fitts' Road Steamer it was stated that "the pulling capacity was from ten to twenty tons on tracks." The last word should have read "trucks."

"A DROP OF JOY IN EVERY WORD."

FLEMINGTON, Hunterdon Co., N. J., June 26, 1874.

DR. R. V. PIERCE, Buffalo, N. Y.:

Dear Sir:—It is with a happy heart that I pen these lines to acknowledge that you and your Golden Medical Discovery and Purgative Pellets are blessings to the world. These medicines cannot be too highly praised, for they have almost brought me out of the grave. Three months ago I was broken out with large ulcers and sores on my body, limbs and face. I procured your Golden Medical Discovery and Purgative Pellets, and have taken six bottles, and to-day I am in good health, all those ugly ulcers having healed and left my skin in a natural, healthy condition. I thought at one time I could not be cured. Although I can but poorly express my gratitude to you, yet there is a drop of joy in every word I write. God's blessing rest on you and your wonderful medicines is the humble prayer of

Yours truly,

JAMES O. BELLIS.

When a medicine will promptly cure such terrible eating ulcers and free the blood of the virulent poison causing them, who can longer doubt its wonderful virtues? Dr. Pierce, however, does not wish to place his Golden Medical Discovery in the catalogue of quack patent nostrums by recommending it to cure every disease, nor does he so recommend it; but what he does claim is this, that there is but one form of blood disease that it will not cure, and that disease is cancer. He does not recommend his Discovery for that disease, yet he knows it to be the most searching blood cleanser yet discovered, and that it will free the blood and system of all other known blood poisons, be they animal, vegetable or mineral. The Golden Discovery is warranted by him to cure the worst forms of Skin Diseases, as all forms of Blisters, Pimples and Eruptions, also all Glandular Swellings, and the worst form of Scrofulous and Ulcerated Sores of Neck, Legs or other parts, and all Scrofulous Diseases of the Bones, as White Swellings, Fester Sores, Hip Joint and Spinal Diseases, all of which belong to Scrofulous diseases.—*Com.*

SUBSCRIBERS are requested to examine the printed address on their papers. If mistakes occur at any time, please report them to this office. The last figures (at the extreme right) represent the year that your subscription is paid to. Next to these the day and month is represented. For instance, your subscription being paid to July 4th, 1876, it would be represented, viz: 7-4-76; or 4/17/76; or July 4, 76.

General News Items.

JAMES LICK has made public his revised deed of gift. It gives his son \$150,000, \$500,000 to himself, instead of \$25,000 annually, as heretofore; \$540,000 for a school of mechanical arts, \$700,000 for the observatory, and reduces the appropriation for the Capitol to the city hall here. The Key monument is to be done for \$60,000 instead of \$150,000. The other appropriations remain unchanged.

SECRETARY BRISTOW has commenced a searching investigation of the doings of a gipsy whisky "ring." A large number of distilleries have been seized in Southern and Western States and internal revenue officers arrested for complicity in defrauding the government.

It is estimated that the total loss from the glanders at Benicia barracks—the horses killed and the harness and stables burned—was between \$30,000 and \$40,000. It is thought, however, that the disease and every germ of it has been exterminated.

A FIRE at Napa on Friday morning, the 14th inst., destroyed six wooden buildings, owned by Judge Hartson and occupied by six different persons and firms. The total loss will be about \$20,000; insured for nearly half that sum.

THE Southern Californian has been enlarged, and under the able direction of Mr. Julius Chester is doing good service in making known the agricultural wealth of Kern county.

THEY have a social ulcer fastened upon the municipality of Napa known as Spanishtown, which the Reporter demands shall be removed.

THEY have a printing press connected with the Gilroy Academy, and the pupils have the privilege of learning to set type.

It is hoped that most of the mines in Pennsylvania, where work was interrupted by the strikes, will resume operations within a week.

THEY have a street car driver in this city who has been on duty fourteen hours per day for 460 consecutive days.

GEN. JOHN C. BECKENRIDGE died at his residence, Lexington, Kentucky, last Monday evening.

W. C. RALSTON has disposed of his one-half interest in the Palace Hotel to Senator Sharon, for \$1,750,000.

MIAO-SOU is threatened with a grasshopper pestilence.

PRINCE NAPOLEON favors a Republic in France.

SENATOR NYE is hopelessly insane.

Industrial Items.

SINCE the opening of the Lincoln coal mine in Placer county, a stratum of excellent potter's clay has been discovered between the layers of coal. A company to utilize the deposit has been formed in Chicago.

A GENTLEMAN lately returned from the San Geronimo pass, reports to the Los Angeles Express that the Southern Pacific officials have the road graded beyond the Summit to the very edge of the desert.

A GENTLEMAN in Albany, N. Y., intends furnishing his residence with redwood, and Col. Armstrong, of Santa Rosa, writes that he can deliver it in New York for \$60 per M.

THE first assessment of \$5 per share on the stock of the Petaluma and San Rafael railroad has been paid up. Bids for cutting the tunnel near San Rafael will be received up to the 21st.

PROGRESS is the order of the day in Lane county, Oregon, and the Commissioners are ordering bridges rebuilt and roads improved without once stopping to count the cost.

THE people of Woodland, Yolo county, have organized a company to build a railroad from that place to Clear lake, and thence to Humboldt bay.

THE Grangers of Eugene, Oregon, and vicinity, have incorporated a company having for its object the erection of a mill at that place.

It is reported that Stanford, Crocker & Co., contemplate purchasing the newly-discovered coal mine near Cholaine valley, San Benito county.

THE graders are at work on the fourth mile of the Los Angeles and Independence railway, between Santa Monica and Los Angeles.

THE carpenter work on the Petaluma woolen mill is completed, and the work of setting up the machinery is progressing.

THE distillery connected with the Sacramento sugar was burned last week. Loss \$6,000.

THE Point Arena paper mill is turning out 125 reams of straw wrapping paper daily.

THEY have a telegraph line from San Rafael to San Quentin.

THE rapid falling of the Sacramento river is an indication of the shortness of the water supply in the mining regions north. Many gravel claims generally will have to be shut down for want of water this season earlier than usual.

- The Annie Belcher Quicksilver Mining Company, Sonoma County.
- The Geyser Quicksilver Mining Company, Sonoma County.
- The Cloydale Quicksilver Mining Company, Sonoma County.
- The California Borax Company (Sulphur Banks), Lake County.
- The Abbott Mine, Lake County.
- The Buckeye Mine, Colusa County.
- The Cerro Bonito Mine, Fresno County.

KNOX & OSBORN.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

(PATENTED MAY 26TH, 1874.)
Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.
To Supls. of Quartz Mills and Mining Men generally:
We take pleasure in stating that owing to the rapid
increase in our orders, our Pittsburg Manufacturers
have been compelled to add largely to their works—
a new gas furnace and heavier trip hammer—and are
thus enabled to reduce the cost of steel and at the
same time produce SHOES AND DIES superior to any yet
manufactured. We have consequently reduced the
price to 16 cents per pound and solicit a trial order,
guaranteeing that you will find them at least 10 per
cent cheaper than the best iron. There are no STEEL
SHOES AND DIES made excepting under our patent and
sold at this office, or by our authorized agents, though
certain Eastern manufacturers advertise STEEL SHOES
AND DIES which are only cast iron hardened by the
addition of a composition. They will not out-wear two
sets of common iron, though called steel. They are
very brittle and are not capable of being tempered,
flying from under the hammer like cast iron. Our
STEEL SHOES AND DIES are in use in many of the largest
mills on the Pacific Coast, and all who have tried them
pronounce them cheaper and far superior to iron in
every respect, even at the old price of 20 cents per
pound. Their advantages over iron are cheapness on first
cost, increased crushing capacity, time saved in chang-
ing and in setting tappets, increased value of amalgam
by absence of iron dust and chipping, and a saving of
75 per cent. in freight. It takes 60 days to fill orders
from the manufactory East. Price 16 cents per
pound shipped at San Francisco. Terms Liberal.

Address all orders, with dimensions, to
CAST STEEL SHOE & DIE CO., Room 1, Academy Building, S. F.

"Sheep Back" Rocks.

In a recent issue we gave a description of the "Mountain of the Holy Cross," in Colorado, and spoke of the trip of Hayden's party down the Eagle river, in trying to discover a means of access to the mountain. A little stream joins the Eagle river from the west side, which rises among the group of mountain peaks of which the "Holy Cross" is the most conspicuous. The valley of this stream varies from one-eighth to one-fourth of a mile in width, and is about eight or ten miles in length, and so covered with rounded glaciated forms of granite that it was impossible for the party to proceed with pack trains.

The most remarkable feature of this wonderful region is the proof of a great ancient glacier which must have filled up the valley from mouth to source. The bottom extending high up on either side, is covered with the rounded granite masses, varying in size from a few feet to several hundred feet length; so that looking down upon them from a high point, they resemble a huge flock of sheep, as our illustration shows, and from this fact they have received from the Alpine geologists of Europe the appellation of "Roches Moutonnes." It is most probable the valley itself has been worn out of the granite mass. The mountains on either side rise to the height of 2,000 to 3,000 feet above the valley, and the glacial markings are visible 1,200 to 1,500 feet. The moraine deposits on the northwest side reach a height of 1,200 feet above the stream and form a sort of irregular terrace, which, when cut through by the little side streams, show that it is made up of gravel and boulders much worn. In some instances there are well worn cavities in the sides of the mountains, showing how the running water in connection with a mass of rock, formed the cavity, much as a "pot-hole" is made in our streams at the present time.

Many of the "sheep-backs" are still covered with a crust-like enamel, but usually this has peeled off. There is no doubt that all these rounded granite masses were originally covered with what may be called a glacial crust, which has scaled off, so that only remnants remain at the present time. The rounded masses of granite are mostly oblong in form, or lie in parallel lines, as if the little stream had originally occupied a dozen or more channels parallel to each other.

SELF LIGHTING AND EXTINGUISHING LAMPS.—Prof. Wm. H. Zimmerman, of Washington College, Chestertown, Maryland, has invented a lamp which, in general construction, resembles an ordinary student's lamp. The improvement consists in an apparatus on purely scientific principles, attached to the lamp, rendering it self-lighting and extinguishing. The apparatus is simple, and not liable to get out of order, and so cheap, as to the chemicals employed, as not to cost in a year more than would the matches consumed in the usual way for that period. A slight pressure of the finger on a key infallibly lights the lamp without touching globe or chimney. On the other hand, squeezing a gutta puruha ball with hose connection as instantly extinguishes it. Like the ordinary student's lamp, it revolves and can be elevated at pleasure. Kerosene is the fluid used, but any other can be substituted. This is a practical invention, and if some manufacturer gets hold of the patent, who will introduce it properly to the public, lamps of this character will no doubt become quite common.

"GOLD FROM THE GRASS ROOTS DOWN."—A Montana paper says: "Gold from the grass roots down," is an expression not understood in the States, and yet some of the richest placer diggings worked in Montana were of this description. We have got \$2.50 to the pan by pulling up the grass roots on Carpenter's bar, Blackfoot, and washing them, and we have \$5 washed from a pan of grass roots pulled from the rim of Harris' hill, below Bannock. The gold was coarse, and in both cases the grass roots reached the bedrock. Thousands of miners have worked diggings of the kind down as gold from the grass roots down.

Improved Quicksilver Furnace.

John M. Cutler, of Healdsburg, Sonoma county, California, has recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, an improved quicksilver furnace, a representation of which is shown in the accompanying engraving. The improvement consists in combining with an upright or stack furnace an interior upright chamber or

ing between the fireplaces so that the ore will pass readily through the chamber and out through the discharge opening. The upper end of the chamber passes up through the roof of the furnace and has constructed over it a feeding device consisting of a hopper and screw conveyor by means of which the pulverized ore is constantly fed into the chamber. In the rear portion of the chamber is constructed a fume chamber with which an opening in the rear wall of the chamber communicates. An

VIEW ON ROCHES MOUTONNES CREEK, COLORADO.

retort into which the pulverized ore is fed continuously at the upper end and withdrawn through a discharge opening at the lower end, while the heat and products of combustion pass from the fireplace into the body of the main furnace so as to surround the chamber and convert it into a muffled furnace, thus converting or withdrawing the gaseous or volatile portions without drawing with them the soot and products of combustion which usually accompany them, and from which the condensed product is difficult to separate.

Inside of the ordinary upright furnace is constructed an upright chamber, as shown in the engraving, which extends from the top of the furnace down to near the fireplaces. This chamber extends directly across the furnace between the fireplaces in the manner of a partition, and is narrow enough to provide a space directly above the fireplace between the sides and the walls of the furnace, thus exposing a large wall surface of the narrow chamber to the heat. Pipes and tubes pass, as shown, through and across the chamber so as to open into the combustion chambers on each side of it, in the manner of placing tubes in a tubular boiler.

On each side of the chamber is constructed a small chamber which extends almost to the top of the large chamber, and these chambers communicate with the main chamber by means of holes, at different heights, for the purpose hereinafter mentioned. The lower end of the upright chamber is constructed with an inclined floor, and this inclined floor leads to a discharge open-

opening in the rear wall of the furnace also communicates with the fume chamber, through which the fumes are conducted from the chamber through pipes to the condensers. It will thus be seen that the inventor encloses a

roasting chamber inside of the furnace, so that the heat will surround, or partially surround it.

The ore to be roasted in this furnace is first pulverized so that it can be fed by the screw from the hopper into the upper end of the chamber. This chamber is kept partially filled with ore all the time, and the spent ore is occasionally drawn out through the discharge opening so as to maintain a uniform quantity of ore in the chamber. The ore as it falls through the feed opening will be distributed by the cross tubes or flues and will surround them closely as it accumulates. The surrounding heat, which is in the outside combustion chambers and in the cross flues, will then be sufficient to roast the pulverized ore in the ore chamber and liberate the volatile portion so that it will rise in the chamber or pass into the side compartments, and pass into the fume chamber through the opening or passage. The lower holes which connect the main chamber with the small side chambers, serve to draw off the fumes from the ore and deliver them through the lowermost holes into that portion of the ore chamber which is nearest the fume opening, thus giving them a free passage through the side chambers.

Holes are also made through the front wall of the furnace so that the operation in the chamber can be inspected. The inventor thus

provides a muffled furnace or chamber in which ores are roasted without intermingling the products of combustion with the fumes which are generated from the body of ore, and at the same time provide for making the operation continuous. Those desiring further information concerning this furnace, can address the inventor as above.

An Improved Rock Drill.

Mr. George Atkinson, of this city, has recently patented, through the Agency connected with this office, an improvement in drills, which consists of a novel mode of operating and rotating the drill and in the manner of constructing the parts of the frame and mechanism so that they can easily be taken apart, or portions detached at will. The device, which the inventor terms a "chura drill," consists of a supporting frame for the mechanism which is made strong and light and carries the drill, operating cams, driving shaft and supplementary shaft. The drill stands vertically and passes in front of movable cross beams. A lever arm curves around in front of the drill, one end being pivoted to a timber, while the other is held by a spring catch. At the top a cross lever steadies the upper end of the drill and is held and released in the same manner by a catch. The pivoted end of this lever on one side, and the catch on the other side of the frame, are mounted on blocks which are also mounted upon the frame so that they can be turned to one side, and by this means the drill and its supports can be removed so that access can be had to the drill hole without moving the frame.

The driving mechanism of the drill is also mounted on a sliding cross-beam, and a guide which can be moved back for some distance, so as to give additional space. The shaft carries two cams, one being of some size and serving to lift the drill for each blow. The head of the drill has an adjustable sleeve secured to it loosely, and this sleeve is provided with an arm beneath which the cam rises at each revolution, thus lifting the drill, which is then allowed to fall either by its own weight if sufficient, or a spring or additional weight may be added. One cam is considerably smaller than the other, the office of the smaller one being to turn the drill at each rise for a stroke. In order to do this a plate is fitted to move up and down the drill shaft, but so as to turn the drill around with itself. This plate has a ratchet cut upon its lower surface, and the smaller cam engages with a tooth of this ratchet at each revolution of the driving shaft, thus rotating the drill to as to make a smooth even hole. When the drill is to be worked on a level, the frame will stand firmly, so that the drill may work vertically; but if it is to work at an angle the two front legs of the frame must be elevated, and this would render it inconvenient to turn the crank by which the power is provided. The supplementary shaft is therefore mounted at a considerable angle with the driving shaft, and properly supported so that the crank may be changed from one shaft to the other as convenience may suggest. This drill is a very simple one, and for light work where steam is not to be used, will be very useful.

REVISED MINING STATUTES.—We have now in press and will shortly issue the Revised Statutes of the United States which relate to Mining. We recently published a pamphlet containing the Mining Laws of the United States, with the instructions of the Commissioner of the Land Office, blank forms, etc. At the time we issued this, the Revised Statutes of the United States had not come out. Since then we have received a copy of these Statutes and will add to the pamphlet referred to all the material relating to mining which appears in the revised Statutes. Those who have already purchased the pamphlet will receive this supplement free on application to this office. The Revised Statutes will also be published in the MINING AND SCIENTIFIC PRESS. With the additions now made the pamphlet printed by us will contain in *extenso* all laws of the United States relating to mining, and the cheapness of the publication—fifty cents—places it within the reach of all.

EXTENDING THE AIR SHAFT IN THE BELCHER MINE.—The air shaft in the Belcher mine, below the 1000-ft level, is going steadily forward.

Cutler's Improved Quicksilver Furnace.

The Stock-Jobbing Juggernaut.

We take the following suggestive article from the San Francisco Chronicle of May 20th:

In the city of San Francisco there is a great banking institution, at whose head and in whose directory are many of our first, best and most prominent citizens. On our coast there is a silver mine, the oldest in point of discovery, one of the richest in point of reputation, and fittingly named after that mysterious land visited by King Solomon and Hiram of Tyre for precious metals for the adornment of the temple. In the list of trustees of this mine, who number seven, the chief stockholder of the bank has a cousin by marriage; one it owns by right of appropriation, making use of him as St. Paul utilized his hired house at Athens; another is a brother; another is a private secretary; another is the land agent and confidential real estate operator of the bank; and the remainder are presumably friendly birds, as they are of the same plumage and roost in the same cage.

The President and Directors of the Ophir mine are: President, J. D. Fry; Directors—A. K. P. Harmon, James Freeborn, Joseph Sharon, James H. Dobinson, Maurice Dore and James A. Pritchard. This mine embraces 108,000 shares, a majority of which have from time to time been owned by people interested in the bank. One year ago shares of this mine were selling at \$8; its highest point of advancement within the year has been \$315 per share; its value by yesterday's sales was \$36 per share. The variations in price have been wonderful in range, and have occurred with astonishing suddenness; a single twenty-four hours has made a change in value of five millions of dollars. The bank, as we have been informed, has loaned money upon the stock at prices more than five times its present value. Mining experts and engineers believed to be in the pay, and supposed to be in the confidence of the bank ring, have given their earnest testimony as to the richness of the mine, the breadth, depth, and assay value of its ores. The confidential and personal friends of Messrs. Sharon, Ralston, and Mills have proclaimed their confidence in the mine as a permanent investment. Statements intended to give trust in the mine have been industriously circulated upon the street and whispered into confiding ears, purporting to come directly from gentlemen who own, manage and control it. The brokers who are supposed to represent the owners do conduct themselves in the Board of Brokers as to promote the advancement or depression of the stock. Just at the moment the stock market is the most disturbed, while panic is on the ragged edge of want of confidence, when margins are threatened and fortunes hang upon a rumor, when every anxious holder looks for some ray of hope to the Directory, these agents, brothers, cousins and friends of Messrs. Sharon, Ralston, and Mills proclaim an assessment, and it is announced that the prosperous mine named Ophir, which has been taking out one hundred and fifty tons of ore per day, and whose value, according as it was desirable to elevate or depress the stock, has varied from \$40 to \$700 per ton, requires \$216,000 to pay working expenses.

William Sharon is accredited with the control and direction of the mine. Mr. Ralston is supposed to have had large interests in it, and his relations with Mr. Sharon are intimate in business. D. O. Mills, late President of the bank, is supposed to be represented by James H. Dobinson, who is set down in Langley's Directory as his private secretary. He is also clerk to William Sharon and Secretary of the Union mill and mining company. Mr. Sharon is one of the reported owners of the Virginia Enterprise and the Gold Hill News, printed where the mine is located. These journals, for one year past, have written up this mine as one of great value; its discoveries have from time to time been announced as of startling importance. The highly wrought descriptive accounts of the extent of ores and richness of assays made by these journals would justify investment even at the highest price attained by this stock during the year, and we are not prepared to say that these articles have not, in the main, been correct, as we are not endeavoring to underrate the value of the mines at Virginia City. We raise no issue with these journals as to the truth of their descriptions, nor do we question the good faith of the writers.

If this mine is honestly administered it has been an unfortunate thing for the Pacific coast. It has ruined men and women; it has demoralized values and industries; it has destroyed confidence in mining property; it has made men distrustful of their fellow men. Unless there is an altogether mistaken impression abroad in the community, the wrong lies not in the mine, but in the management. It is believed that these alternate excitements and depressing prices, are the result of carefully devised and adroitly managed manipulation. It is believed that the gentlemen whose names we have felt it our duty to mention, are through these practices acquiring from the community in which they live, and at its expense, vast fortunes. It is believed that a systematized plan of operations is carried on, in which large capital, subtle intrigue and unscrupulous misrepresentation are resorted to for the purpose (we intentionally use a mild word) of draining from the many to enrich the few. Mining is necessarily a hazardous business, but if to its ordinary hazards there is added the crime of false suggestion and false suppression of facts, these

transactions in stocks cease to be operations or investments, and the buyers and sellers become the victims of a criminal conspiracy, and are robbed of their money. With a view to illustrate how these mining operations are interwoven with such other, and with a view to give our readers food for reflection, we append the names of some of the mines in which may be found as trustees the same individuals who figure in the Ophir Directory. This unusual number of trustees in a mine is five; we do not say that a bank ring can or do control all or any of them. In the Alpha Consolidated trustees are found the names of J. D. Fry and A. K. P. Harmon. In Escher, J. D. Fry, James H. Dobinson, A. K. P. Harmon, and Robert F. Morrow. In Ocholar-Potosi, A. K. P. Harmon, J. H. Dobinson, J. D. Fry and James Freeborn. In Crown Point, J. D. Fry, A. K. P. Harmon and J. H. Dobinson. In Challenge Consolidated, A. K. P. Harmon, J. D. Fry, William Sharon, J. H. Dobinson and James Freeborn. In Caledonia, A. K. P. Harmon and E. M. Fry. In Confidence, K. F. Morrow, A. K. P. Harmon and J. H. Dobinson. In Gold Hill Quartz, J. H. Dobinson. In Dayton, A. K. P. Harmon. In Empire, A. K. P. Harmon and J. D. Fry. In Eclipse, James Sharon and J. H. Dobinson. In Imperial, A. K. P. Harmon, J. D. Fry and J. H. Dobinson. In Meadow Valley, J. D. Fry and R. F. Morrow. In Monitor, J. D. Fry. In New York Consolidated, J. D. Fry and A. K. P. Harmon. In Overman, R. F. Morrow and J. H. Dobinson. In Raymond and Ely, A. K. P. Harmon and R. F. Morrow. In Segregated Belcher, R. F. Morrow, A. K. P. Harmon and J. H. Dobinson. In Savage, J. D. Fry and R. F. Morrow. In Sierra Nevada, R. F. Morrow and A. K. P. Harmon. In Silver Hill, A. K. P. Harmon and J. D. Fry. In South Comstock, A. K. P. Harmon. In Trench, Jas. H. Dobinson. In these mines there is invested millions by honest toiling men, men of business and limited means. These trustees occupy a sacred relation to the share-owners, and the share-owners number a host of confiding, simple minded, honest people. In the management of the mine there should be economy and integrity; every dollar received and expended should be accounted for as by a bank or insurance corporation. Every share-holder has the same right of information as Mr. Morrow, or Harmon, or Fry. If the mine is not so conducted, it is dishonest; if information is withheld, it is dishonest; if by innuendo or false suggestion, or by a suppression of facts, share-holders are induced to sell or buy, they are defrauded, and the men who manage are rogues and robbers. They obtain money under false pretences; and although the false token required by the Code is wanting, they are, nevertheless, guilty of crime.

And now that we have described the temple of the stock-jobbing Juggernaut, its idols and its priests, given some hints of its interior workings, we can only say to our intelligent readers, do as you please. If you believe you can cope with these inside managers of mines successfully, do so. If you think you stand upon such equal terms in point of information as gives you an even chance with them to win at this hazardous business, go in; these persons will roll so long as you make the game. Dealing in mines under honest and honorable management is a hazardous business. Dealing in stock under dishonest and dishonorable management will result in inevitable loss.

ETNA SULPHUR MINE.—James McAllister, of Mill City, one of the discoverers of Etna sulphur mine, near Table Mountain, arrived in town last night, and gave us the following particulars of the find: The sulphur bed is located on a hill about ten or twelve miles north of the Humboldt salt marsh, on the east side of Table Mountain range. It was discovered by McAllister and Elliot, who located four quarter sections of the mound in which it is situated, and which appears to be principally sulphur. There is a depression in the summit of the mound which looks like the crater of an extinct volcano, and from which gasses, emitting a strong sulphurous odor, were escaping. He thinks there is an immense deposit of sulphur in the locality, but as he and Elliot were not prepared to prospect it, they did not dig more than a few feet into the bed in any one place, but they satisfied themselves that the greater part of the surface was covered with sulphur to a depth of at least two feet, though for aught they know to the contrary it may extend downward to an indefinite depth. He says any number of teams can be loaded there by shoveling the sulphur right into the wagons, and that it can be hauled up Pleasant and Grass valleys to the railroad for \$12 per ton.—*Silver State.*

A MINERAL belt has recently been discovered in the foothills of the eastern slope of the Humboldt range of mountains that can be easily traced from Unionville to Humboldt City, a distance of twenty miles. Several locations have already been made on this belt, and considerable work done in different places, and good prospects obtained in every instance.

IN THE Utah mine, on the Comstock, putting in the foundations and preparing for the erection of the heavy bed plates and sills for the new and powerful machinery is making steady headway. This machinery when completed will be among the most improved and powerful on the line of the Comstock.

THE N. Y. Consolidated company are tearing down their old works, and will put up more substantial ones.

The New California Mill.

The site selected for the new California mill is on the brink of the large ravine which puts down from the neighborhood of the cemetery, and thence on into Six-mile canon at the Nevada mill. As the ravine makes to the south and east to join the canon, the site is a short distance north and west of the Nevada and some distance east of the new C & O shaft. The grading for the mill, which has been very heavy, is now about completed. It has been going on at the rate of two thousand cart-loads of dirt and rock per day, ten carts having been used on each shift. As the work is approaching completion the forces have been somewhat reduced, and only eight carts are used on the day shift and six on the night. Some very hard blasting rock has been struck near the southwest corner, which has made progress a little slower than at first.

The system of loosening up the dirt which has been adopted by T. H. Rooney, Esq., under whose supervision the work is done, is ingenious and the result of long experience in the business. The grade is from seventeen to nineteen feet in depth, and in order to lift and loosen the earth holes seventeen feet in depth are drilled with old-fashioned churn drills eight or ten feet from the edge of the grade. Into the bottom of these are placed a couple of cartridges of giant powder, then the hole is tampered about six inches above these cartridges and they exploded. Any one not experienced in this kind of work would expect some sort of a demonstration of effect from such a confinement and explosion, but the perceptible result is small. Even the hole drilled in is not injured by the discharge. The result attained is the formation of a large underground chamber. This is the peculiar compressing, gravitating effect of the giant. Of course, hard rock would be broken, but in a commixture of earth and loose rock it simply makes room for itself, and the result is the underground chamber before mentioned. This chamber is now filled with black powder—all that it will contain—and the hole tamped full to the surface. When this is exploded it lifts and pulverizes the whole mass so that no more picks are necessary for the primary breaking and loosening of it. This is one secret of the exceedingly quick work made of this large and heavy grade.

In order to pass the water which flows from the city round the mill site, a 3x3 flume, made of three-inch lumber, has been constructed, running along on the north side of the ravine and emptying below where the mill will be placed. This is being covered by the grade, so that it will be almost entirely out of sight when the work is completed. It will take about six days more to complete the grading. It is the intention then to go at once to work constructing the mill. In fact, the first load of lumber which is to be used in its erection was dumped on the grounds yesterday. It was three weeks on the 9th instant since the first pick was struck into the ground. At this rate the mill will be up and running so as to exceed the \$5,000,000 net proceeds of the California before January 1, 1876. The first shipment of freight for the mill was also received yesterday at the depot of the Virginia and Truckee railroad. It consisted of two boilers, 64x16, and two double breechings; total weight, 20,000 pounds.—*Virginia Enterprise.*

AGRICULTURAL AND MINING LAND.—An idea prevails, and not without some reason for it, that there is something wrong in the law that surrenders lands for agricultural purposes which are worth, in some instances, a hundred times as much for mineral purposes. At the rate lands are being taken up it will only require a few years to put a terrible check upon mining, and as it stands to-day the discoverer of a mine or one who is willing to work it, either has to suspend work or engage in a lawsuit that requires both time and money to adjust. We are informed that there are several places near town where men could make their three or five dollars a day, but the diggings are locked up by government patents in the hands of parties who are not even willing to cultivate the soil. We believe our county would double its population in a year if this drawback upon our great industry did not exist. We believe that men should own property and be fully protected in their possession of the same, but we believe that no one should be prohibited from digging gold in any locality where it exists to an amount greater than the value of the land. This, we believe, is the intention of the law, but it is misapplied in many instances, and a remedy easier than a heavy lawsuit ought to be put in force.—*Placer Argus.*

DECISIONS IN MINING LAND CASES.—In the matter of the gold and ore placer claim, at Marysville, California, a decision has been rendered by the Land Office regarding the claim of daughters and others upon the ground that the adverse claimant had not shown citizenship or compliance with the law in holding his claim in January last. The Secretary of the Interior affirms the decision of the Land Office that the claim in Montana, located prior to the Territorial Act of 1873, could not exceed 100 feet. A subsequent hearing of the case was had, but the Secretary has just overruled this motion and re-affirmed his former decision.

The Richmond Refinery.

The refinery, or separating works, of the Richmond company, says the Eureka Sentinel, give promise of doing much more for the general well of this section than many could have been led to suppose. The benefits derived from refining our base bullion at home can scarcely be over-estimated, and that it will redound to the interests of poor men and the general prosperity of the whole district does not admit of a doubt. Heretofore it required months to get returns from bullion shipped either east or west. This was particularly trying on small operators and men of limited means. Fortunately, by the construction of the refinery, all this is changed. Now, bullion may be deposited at the refinery one day and its full market value in coin is ready the next. This ought to operate as a great stimulant to the owners of mines who have not the means to carry on business on a comprehensive scale. The utter impossibility of obtaining speedy returns for our bullion has all along proven one of the greatest obstacles we had to contend with. It required more than a princely fortune to keep a mine and smelting works afloat until the coin could be realized for their product. Indeed this was the rock upon which the hopes of several of our smaller concerns were wrecked, as many worthy gentlemen in this community can attest from dearly bought experience. The promised early completion of the Eureka and Palisade railroad is also another of the beneficial results of the Richmond refinery. There can be no question that our ability to extract the precious metal from the base will greatly accelerate the construction of the unfinished division of this important enterprise. Other benefits will of course accrue to this community, but those cited are deemed sufficient to establish the Richmond company's claim to a very large share of our confidence and esteem. To Mr. Probert, the resident Director, through whose sagacity and energy these incalculable benefits have been vouchsafed us great credit and consideration is due, and we assume the liberty of tendering him the sincere thanks of the entire community.

A Quicksilver Bonanza.

The Vallejo Chronicle a few days since alluded to the fact that the owners of the St. John mine had reached the ledge for which they had been driving with their big tunnel. The developments made by the new tunnel show an immense body of ore. The ledge has been stripped a distance of twenty feet long and fifteen high, exposing its whole face. The ore is remarkably rich, being about fifteen or twenty per cent. Miners will have a better idea of the magnitude of the development on being told that the workmen have contracted to break the ore down and take it out of the tunnel at the low price of two dollars per ton.

The Big Tunnel.

The big tunnel of which we have been speaking, that has secured such important results, was begun over a year ago, and work upon it has been prosecuted steadily ever since. It is the sixth level of the mine, and is 650 feet from the surface. The total length is 1,150 feet; it is eight feet high, and well timbered the whole distance. It cost \$12,000 to run it. The striking of ore in this tunnel therefore proves a body of ore 650 feet deep. What its thickness is at this last level must yet be determined by development; but there is every reason to believe that the ore is

Still Growing Larger

As it goes down. On the first level—50 or 60 feet from the top of the hill—the ore body was only one foot thick on the foot wall and four feet on the hanging wall. Seventy-five feet down it has increased fifteen feet, and on the Wilson level, 450 feet down, the body is found 60 feet thick. It is therefore supposed with good reason that in the big tunnel, 200 feet below the latter, the bonanza is larger still. It has a uniform width of about thirty feet the whole way down. With these last developments, there is now no necessity for any further prospecting; and all work in that direction has been stopped. The ore in sight is sufficient to feed all the furnaces.

For Years to Come.

There are fourteen tunnels now run in the mine and in every one cinnabar is found. The company are preparing to run the mine on a scale commensurate with its developments. As we have before stated they have leased the Brownlie mine furnace and will erect another furnace at their mine this summer. This will give them three furnaces, which ought to furnish a smelting capacity of from 300 to 500 flasks a month. The mine will make a very big run the present month.

Those wonderful mines in Southern Oregon, about which so much interest has been aroused, are peculiar in one respect. Instead of being the cause of "flush times," as is usual in the early history of every mining camp, it appears that common labor at the mines commands only one dollar per day, and that wages and prices generally are proportionately low.

The new incline engines for the Ophir mine are of sufficient power to work the mine to a depth of 5,000 feet.

MECHANICAL PROGRESS.

Progress in Iron Work.

At a meeting of the New York Society of Practical Engineering, held on the evening of the 22d ult., George E. Harding, M. E., read the regular paper on "The Progress of Invention in the Metallurgy of Iron," reviewing the successive steps by which this industry has arisen from its primitive methods to its present complex processes and colossal proportions. He stated that the next step forward to be made in iron manufacture is the production of shaped articles direct from the ore, without reheating or intermediate processes. At the close of Mr. Harding's paper, the Hon. Abram S. Hewitt made an extemporaneous address on the most recent successes of iron making. Among other matters of interest he stated that the production of iron direct from the ore is easy by the use of charcoal, but not with hard coal. This direct production of iron is not, however, of the same importance as it was formerly, for the reason that steel may be made direct, and as so rapidly taking the place of iron for many purposes that the production in Great Britain has risen in a few years from 20,000 tons to upward of 1,000,000, and in the United States already amounts to 500,000 tons per annum. The elimination of phosphorus from iron is no longer the problem that only recently has been the case, for it has been found that by eliminating the carbon instead, a good steel can be made, containing as much as four-tenths of one per cent. of phosphorus. Good steel may contain either carbon or phosphorus, but not both together. The result of this discovery will be to open up immense tracts of American iron mines that hitherto have been of little worth. The midsummer session of the Society of Practical Engineering will be held in July next.

Expansion and Contraction of Boilers.

One difficulty to be contended with, in the management and working of steam boilers, arises from the unequal expansion and contraction of the parts of the structure. In some instances these are so great as to be the cause of more wear and tear than any other process to which the boiler is subjected.

Iron expands in volume one-eighth hundredth; or, in other words, a bar of iron one inch square and 800 inches long would expand one inch in length while heated from the freezing to the boiling point of water. The proportion of expansion, for any length of bar, corresponding to any length of boiler, can be easily estimated. It is not to be understood, however, that the maximum expansion would occur in boilers generally, for it is rare that one is allowed to get so low in temperature as thirty degrees. Still, in the winter season, boilers when "blown down," are liable to become very cold.

From experiments made by M. Wertheim, he concluded, from certain phenomena, that there is a kind of thermal elastic limit with iron. "When heated, and when its consequent dilation of volume does not exceed that which corresponds to the boiling point, it returns to its original dimensions. Beyond a certain temperature it does not contract again to its primitive volume, but takes a permanent dilation in consequence, apparently, of its elastic limits having been exceeded."

THE EXTENSION OF THE IRON TRADE IN JAPAN.

The Government of Japan is taking steps for establishing blast furnaces, in which the excellent magnetic iron ores averaging above fifty per cent. metallic iron, and which occur in lodes, are to be smelted both with charcoal as well as coke. The iron hitherto manufactured in Japan has been made, as described in a former report, from the iron sands which occur in the islands of Yesso, by a sort of bloomery process, and these iron sands have lately been described in the report of Mr. B. S. Lyman, the geologist and mining engineer to the Government of Japan, as consisting of two varieties, the one easily smelted and pure, whilst the other is difficult to smelt, and supposed to contain titanium. He estimates the total quantity of these sands at 125,000 tons, which he regards as containing 91,000 tons metallic iron, but states that only some 5,500 tons of the sand are of the easily smelted description. —Iron and Steel Institute.

A GUN MANUFACTURED IN AN HOUR.—A gentleman recently called at the Remington gun manufactory at Ilion, N. Y., with the view of asking the purchase of some arms. He was shown through the works, and evinced great interest in all the processes. At the close of his tour of inspection a gun was shown him and repeatedly discharged in his presence. He was then told that since his entrance into the works every part of the identical gun just fired had been manufactured and put together, and that his own eyes had witnessed every stage of the work. He then offered to purchase five or six loads of guns which the Spanish inspectors had recently rejected, probably with the view of getting some small reduction, and paid the less. Remington the price named in the original contract. It is supposed that this gentleman was an agent of Don Carlos. If this be the case the Spanish government has through its officials quite overreached itself.

American Ordnance—A Novelty in Gun Manufacture.

Before the war of secession our guns were the most powerful in the world; but since that we have made no progress in that direction, while the nations of Europe have gone a long way ahead of us. There is not in the United States to-day a private or public factory capable of forging a 100-pounder of steel or wrought iron, and the proposal by a bureau officer to purchase suitable guns from abroad would be justly construed as a gross affront to the American eagle. Urgent appeals have been made every year to Congress with a fall representation of the case, but with little effect. Congressmen seem to think but little of the necessities of national defence. The contingency of a foreign war is apparently regarded as so remote that it is not thought to be worth the smallest insurance premium upon it. It is not difficult to obtain each year a few thousands of dollars for experimental purposes; but when mention is made of the millions necessary to provide a national gun factory, Congress declines with astonishment the unwelcome proposal.

After many efforts the Ordnance Department succeeded in obtaining, two years ago, an appropriation for constructing and testing some heavy rifles. It was provided, in the act that one of these should be a breech-loader. A board was appointed to select the models, and those chosen were: 1, a 12-in. Krupp; 2, a 12-in. Woodbridge muzzle-loader; 3, a 12-in. Hotchkiss muzzle-loader, besides several minor recommendations. The Krupp gun was never negotiated for, because it soon became apparent that the other projects would more than allow for the appropriation, and American genius must be encouraged, not affronted. Hotchkiss' gun has been much elaborated and modified, and the inventor expects to have his gun finished during this spring, if the funds hold out. This gun is made up by welding together iron disks, and then boring out. The plan is an old one, and failed in the hands of Dr. Ames, the gun separating into sections at the welds. Hotchkiss' improvement consists in his method of welding.

The Woodbridge gun is in most respects a novelty. He proposed his plan as long ago as 1850, when his proposal was favorably endorsed by General Scott. During the war a small gun was made by him and could not be ruptured.

His plan consists in winding about a steel tube a coil of soft steel wire. The wire is fed to the coil in a band consisting of twenty or thirty wires, each wire of three-tenths of an inch cross-section. When the coil is wound up the whole is placed in a tight flask of boiler iron, and this is put into a specially constructed furnace, muzzle upwards, and heated to redness. An alloy of 80 of copper and 20 of tin is then poured into the flask. This is a very fusible alloy, and is expected to solder the wires into a practically homogeneous mass, and to give trunnions and contour to the gun. If this succeeds the finishing of the gun is of course mere lathe-work. This project seems at first to have some of the Munchausen elements in it; but a very careful study of the elaborate details of the plan, and of Mr. Woodbridge's preliminary experiments, led every member of the Ordnance Board to the belief that it was worth trying. It is known that bronze penetrates with astonishing power between clean surfaces of iron or steel, when the latter is hot enough to preserve the fluidity of the bronze, and when the surfaces are thoroughly clean. This has been abundantly verified at the Springfield armory. Moreover, the small gun made by Dr. Woodbridge in 1861 was out into small pieces, and was found to be homogeneous and solid throughout. The furnaces, machinery and steel tube for this gun have been procured, and the calibre of the first one is intended to be nine inches, on account of the extreme novelty of the experiment; but if it proves successful a 12-in. rifle will be immediately constructed—or attempted. Difficulty has been experienced in procuring the wire. It is required to be square in section and of three-tenths of an inch in gauge, and as the inventor is extremely exacting and cautious, much difficulty has been found in fulfilling his requirements.

The principle appears to have many points to recommend it. Its longitudinal strength will be guaranteed by the obliquity of the wires, which will be reversed in the alternate layers. It is objected by many that the heating of the coil and its subsequent slow cooling will deprive the wires of a great portion of their tensile strength; but, granting this, there will still be left a very high tenacity, as has been shown by Mr. Woodbridge in his extensive preliminary experiments, and, as already stated, the inventor combines with some daring a great and perhaps excessive amount of caution and foresight in providing against possible sources of difficulty and errors of detail, so that good results are very confidently anticipated.

RECIPE FOR A CEMENT FOR MENDING STEAM BOILERS.—Mix two parts of finely powdered litharge with one part of very fine sand, and one part of quicklime which has been allowed to slack spontaneously by exposure to the air. This mixture may be kept for any length of time without injuring. In using it a portion is mixed into paste with linseed oil, or, still better, boiled linseed oil. In this state it must be quickly applied, as it soon becomes hard.

NEEDLE MAKING.—There is a needle factory in New Haven where the whole process is done by a single machine without the manual labor of any person. A coil of steel wire is put in. The machine cuts it off at the required lengths. It cuts the steel pieces consecutively, punches the eye-holes, countersinks the eyes and grinds the points, and in fact does everything until the needles drop out completely formed. Another machine picks them up and arranges their heads and points together, and a third piece of mechanism puts them into paper. One of these machines occupies no more space than an ordinary table, and each of them turns out from thirty to forty thousand needles a day. Most of the needles in use in this country have been imported from England until a few years past.

SCIENTIFIC PROGRESS.

The New Method of Electric Illumination.

Dr. Wilde, of the St. Petersburg Academy of Sciences, has recently made a report to the Academy upon the new mode of producing the electric light proposed by M. Ladyguin, of that city. Since the discovery of the voltaic arc in 1821 by Davy, many attempts have been made to utilize it practically for illumination. But in spite of the regulators devised for the purpose, it still remains variable and inconstant; being too intense used at a single point, it is yet incapable of division. Since the improved magneto-electric machines have reduced the cost of the electric light to only one-third that of coal gas, these efforts to utilize it have been redoubled. And, as a result, M. Ladyguin has made an invention which, in a very simple way, resolves both problems, rendering the light steady, and at the same time capable of division. It has long been known that the electric light proper comes from the intensely heated carbons which the current traverses, the resistance of the air between them developing this heat. So the resistance of a platinum wire placed in circuit causes it to be highly heated; but the light thus obtained, though constant, and entirely controllable, is too feeble for practical use.

M. Ladyguin has conceived the idea of replacing the platinum wire in this experiment by a thin rod of gas carbon, and with complete success. Carbon possesses, even at the same temperature, a much greater light-radiating power than platinum; its calorific capacity is less than one-half that of platinum; it is, moreover, a sufficiently good conductor of heat; so that the same quantity of heat elevates the temperature of a small rod of carbon to nearly double that of a wire of platinum the same size. Again, the resistance of the carbon employed is 250 times greater than that of platinum; hence it follows that a rod of carbon may be fifteen times as thick as a wire of platinum the same length, and yet be heated by the same current to the same degree. Finally, the carbon may be heated to the same intense whiteness without the danger of fusion to which platinum is liable. These are some of the advantages of carbon; its only disadvantage is, that heated in the air it burns, and so gradually wastes. But M. Ladyguin has happily obviated this difficulty by enclosing the rod of carbon in a glass cylinder containing no oxygen and hermetically sealed. Dr. Wilde asks, in conclusion, that the Academy recognize the fact that M. Ladyguin has solved the grand problem of dividing and rendering steady the electric light, in the simplest possible manner, and that they award him, in consequence, the Lomonosow prize.

A New Earthquake Indicator.

A highly ingenious, though simple apparatus, designed by M. Malvosia, of Bologna, to indicate the commencement of earthquake shocks, has lately attracted the attention of Italian savants. We will try, briefly, to describe it: On a slightly inclined board is fixed a spherical cap, having eight grooves, corresponding to the eight principal points of the compass. A little beyond the edge of the cap there is a projecting wooden ring which limits the inclined surface. On the top of the cap is poised a little brass ball, which is slightly flattened at the point of contact. Upon the ball rests, very lightly, a conical weight by a small screw projecting from its base. This weight is suspended by a chain from an overhanging arm, moveable up and down on a support at the side.

It will thus be seen that the least shock will cause the ball to topple over. When it does so it will run down one of the grooves of the cap to the inclined plane, at the bottom part of which it finds a hole, and passing into it, causes the discharge of a pistol. But this is not all. Whenever the ball has left its position on the cap, a spring needle, longer than the diameter of the ball, shoots out from the little screw-knob that rested on the ball and catches in that groove of the cap down which the ball ran.

Thus the direction is indicated in which the shock has been given; it has been on the opposite side to that in which the needle hangs down. The instrument is said to be very sensitive, and will doubtless render good service in what is now a little understood branch of science.

SAFETY-LAMPS NOT ALWAYS SAFE—AND WHY. Twenty-two large explosions have taken place in English coal mines since the year 1866; among these seventeen took place at the moment of the firing of a blast at a distance. Galloway conceived from this the suspicion that a violent sound wave might be capable of pushing the flame through the wire gauze of the safety lamp, and thus ignite the inflammable gas around. It was known that when explosive gases are drawn through a wire gauze with a velocity of ten to twelve feet per second, the flame penetrates and ignites them; but it was not known that a sound wave would do the same thing, and this is what Galloway has proved by experiment. He placed a safety-lamp in an explosive mixture, and fired a pistol at a distance of twenty feet, or ignited a box filled with a mixture of coal gas and oxygen; in either case a large flame was projected through the wire gauze out of the safety-lamp, and ignited the surrounding gas. He found no difference when the gas was separated from the air by means of a thin membrane, which would not permit air currents to pass, but only transmit the sound wave. The experiment was varied by transmitting the sound wave through a tube twenty feet long, and of which the axis was directed toward the safety-lamp; closing this tube with an elastic membrane made no difference whatever. He therefore came to the conclusion that a blast in a coal mine may make all the safety lamps useless, while it explains the fact that an explosion in one part of a mine is often immediately followed by another explosion at a distant point.

NEW METHOD OF PRESERVING MEAT.—A method for the preservation of meat, by keeping it in a cool, dry chamber, has been communicated to the French Academy by M. Tellier, well known as the inventor of very efficient ice-producing machinery. His new device consists in the employment of methylic ether, a substance that is gaseous at ordinary temperatures and atmospheric pressure, but which can be reduced to a fluid by a pressure of eight atmospheres. The methylic ether is condensed and then allowed to expand in contact with metal compartments containing a solution of chloride of calcium, which it reduces to a low temperature. Air is blown through this apparatus, its moisture is deposited as hoar frost on the metal, and it passes in a dry and cold state to the chamber in which the meat is placed. It is found that the flavor of the meat is not injured by retention in this situation for forty to fifty days, although it is said to acquire a greasy taste after that period.

THE PLANET URANUS.—The spectroscope has enabled astronomers to ascertain that the atmosphere of the planet Uranus, which is further from the sun than any other planet except Neptune, is composed chiefly of hydrogen gas. Mr. Proctor says that if there is even a small proportion of oxygen present, an electric spark, however minute, would cause tremendous convulsions by combining the hydrogen and oxygen into water. The *Spectator*, referring to his assertion that there is probably no life upon the planet, asks, "Why may there not be life which needs no oxygen?"

FAILURE OF COPPER SULPHATE.—Railway sleepers injected with sulphate of copper will be preserved indefinitely, provided the copper remains in its original combination with the ligneous tissue. But M. Max Panlet shows that, on railways where carbonate of lime exists in the stone ballasting of the track or in the soil, the carbonate gradually penetrates the wood and substitutes the copper. Decay then follows, for carbonate of lime is not a septic agent.

MUSIC FROM GAS JETS.—An extraordinary new musical instrument, called the pyrophone, invented by M. Kastner, of Paris, has been exhibited at the Society of Arts. The notes are produced by the singing of gas jets in glass tubes, and are sweet and pure, and, at the same time, have great penetrative power. After the reading of the paper on the invention, illustrations of the music emitted were given separately and in concert with the human voice.

NEW ELECTRO-PROCESS.—A very ingenious application of electro-metallurgy has recently been brought before the notice of the Society of Arts. It consists in the application of a coat of silver, by means of electro-deposition, on natural leaves and flowers. By this means very delicate ornaments are produced, since the precise form and texture of the natural leaf is preserved under the thin silver film. The special process by which these results are attained is the invention of a Mr. Denton.

INTERESTING DISCOVERY.—A discovery of a curious nature has been made in Egypt by a savant who has found and deciphered an inscription in honor of Toutmosis III., containing more than four hundred geographic names, very precise and recognizable, concerning Arabia, Armenia, Nubia, and the coasts of the Mediterranean. The inscription is thirty-five centuries old, and will give rise to some historic and geographical debate of great value.

LEAD VEINS are evidently formed by the accretion of gaseous particles, and the growth or repletion carried forward by the laws of crystallization. Suppose this crystallization to be under the control of any appposable principle, and each mass of ore (whether in regular cubes or having the edges or solid angles of the cubes truncated) to have direct reference to each other cube, and the key of the filling or repletion of the vein system of a lead field may be had.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

BUNKER HILL.—Amador Ledger, May 22: This mine, situated near Amador City, is being rapidly developed into a valuable property. The main shaft has reached a depth of 270 ft., and the ledge at that depth is very extensive, and the entire mass of ore far beyond the average in point of value. In connection with the mine is a 10-stamp mill, which yields from the rock crushed, from \$7,000 to \$8,000 per month, with an almost unlimited amount of ore now developed. The mine is under the superintendence of Mr. John Palmer, a practical miner, under whose intelligent management the Bunker Hill is rapidly advancing in importance, and may now be ranked with the permanent paying mines of the county. The mill now in use will, at the proper time, be superseded by one of greater capacity, when the monthly yield of the mine will equal the most productive on the great mother lode.

KENNEDY MINE.—As sinking progresses in this mine the prospect of its future value becomes more apparent. The rock taken out in sinking is becoming remarkably rich, far more so than at any former period in the history of the mine. We saw rock taken from the bottom of the main shaft literally filled with gold, and which would yield a fabulous amount of gold to the ton of ore; nor does such rock seem to be of limited quantity; on the contrary, about four feet of the ledge in the bottom of the main shaft is very rich in free gold and sulphurets.

A NEW QUARTZ MILL.—Amador Dispatch, May 22: The owners of the Volunteer mine near this place have already commenced hauling the timbers, etc., for their new 10-stamp quartz mill, which they will erect on the creek a short distance below the mine. This looks like business, and is an evidence that the proprietors have the most implicit confidence in the richness and permanency of their mine.

CALAVERAS.

WEST POINT ITEMS.—Calaveras Chronicle, May 22: Champion, rich as ever. A large quantity of ore on the dump. Mina Rica running levels at the depth of 167 ft., with fine indications that the main north chertony will prove extensive on this level. The Enterprise company are also running a tunnel transversely to the former "Maria." The tunnel is in some 200 ft., and the vein will be tapped in two weeks time. The mill is kept in motion. A. M. Harris crushed a lot of ore from an abandoned mine which yielded \$123.33 per ton. Josephine shaft found 60 ft. Although a large shaft, nothing but pure pay ore is in sight. Some 100 tons are being hauled to the Zacarero mill and will be worked with the appliances available. The superintendent intends to send sample lots of ore to San Francisco to be worked there at prominent reduction works previous to erecting a mill on the mine. Good Faith tunnel is very near the third vein it is intended to tap and will soon be in condition to turn out large quantities of high grade ore. The new shaft on the Doyle mine is down 40 ft.; the machinery is now being used for hoisting. Mr. Carey deserves success for his unflinching energy. A new shaft is being sunk on the Anderson Flat mine, 200 ft north of the working shaft; the two will be connected by a level which has been already started from the south shaft. Times, never better.

FRESNO.

QUARTZ.—Fresno Examiner, May 26: W. A. Sanders, who has lately been visiting the quartz mining region at the head of Big Dry creek, left at this office samples of gold, silver and copper ore which he had procured in that neighborhood. Some of the specimens were very good in appearance. The claim of Barnes & Co. he thinks the best of any that he examined, though none of them were sufficiently developed to enable a proper estimate of their extent or value to be formed. The quartz mill to be erected by Messrs. Jensen & Keys will enable an estimate of the value of the mines to be formed. In our opinion the day is not far distant when a number of valuable quartz mines will be developed to this county and be profitably worked. It is indeed strange if valuable quartz mines do not exist in Fresno when rich ones have been discovered in all the adjoining counties.

INYO.

PANAMINT DISTRICT.—Panamint News, May 18: The Jacob's Wonder is being thoroughly opened and prepared for taking out ore in large quantities. In the west winze, which is now down 76 ft from No. 1 level, 4 ft of \$275 ore is exposed, and the quality is steadily improving as sinking progresses.

STEWART'S WONDER.—Work on this mine is being rapidly pushed ahead, and it will soon be opened by drifts and winzes to a depth of 325 ft.

HEMLOCK.—We have always looked on this mine as one of the greatest on the Pacific coast. It is being most thoroughly opened, and great preparations are being made to supply the mill with its rich ores. The mine is being opened by a shaft 70 ft in depth, from the bottom of which a tunnel has been run in 80 ft, cutting the ledge. From this level a drift has been run east 127 ft, through a body

of fine ore. To the west a drift has also been run 204 ft on the same level. From where tunnel No. 1 cuts the ledge a winze has been sunk 142 ft, through an excellent body of ore. At the depth of 50 ft, drifts have been run east and west 40 ft, showing a body of high grade ore. A tunnel is also being run to cut the ledge at the bottom of this winze, through which all the ore will pass out to a fine road that is being built.

WYOMING.—This mine is being the most extensively worked of any in the district. The preparations and plans for opening it are not only on a large scale but are being rapidly pushed ahead. Tunnels, drifts, winzes and stopes are so numerous in this mine that it is almost impossible to remember them. There has been a tunnel run 185 ft, which cuts the vein at the 287-ft level, and at this level a drift has been run 74 ft west on the ledge, running through the finest body of ore that has ever been found in this mine. The drift has now passed the winze sunk from the 193-ft level, giving fine ventilation to this portion of the mine. The cutting of this vein at the depth of 286 ft removes all doubt as to the permanency of this mine, and settles to the wind the prognostications, made some time ago, of certain incredulous experts, who never can be made to believe that the works and ways of the Almighty are past finding out.

The Panamint Consolidated mining company are working 25 men, running night and day, on their mines.

NEVADA.

IRON MINE.—San Juan Times, May 22: The North Bloomfield gravel mining company have recently struck a bed of blue gravel which is paying immensely. This strata was struck near one of their numerous tunnel shafts and only a few feet below the surface gravel, and about fifty or sixty feet above bed rock. It extends to bed rock and grows richer as they go down. The company is now washing through two monitors, using 3,000 inches daily. Their dam at Bowman's is filled with water, and if no accident occurs they will have a sufficient supply of water to keep the two monitors at work until the fall rains set in. The company now employ about fifty laborers, half of whom, probably, are Chinamen.

HIRSCHMAN & GROVER'S CLAIMS.—Nevada Transcript, May 22: The hydraulic claims of Hirschman & Grover, situated about a mile west of Nevada City, on Quotaham hill, are being worked, and the owners are busily engaged in piping away. The company has 850 inches of water, using two monitors. The remainder of the mining season will be employed in washing up bottom gravel, which is very rich. The water will probably last six weeks or two months longer, and it will take that time to complete their season's work, in securing the large proportion of gold, which is always found on the bed rock. None but white labor is employed in these claims, the owners being satisfied that they can be better served by paying a higher price for white men than employing Chinamen. The Hirschman & Grover claims have had some good clean-ups this season, but the next one, judging from the appearance of the ground sluices, will eclipse them all. There is now no doubt, from the gravel formation and the discoveries continually being made, that the lead is a continuation of the Manzanita and Nebraska claims, and that the main channel runs directly under the Sugar Loaf ridge.

AMERITA.—Foothill Tidings, May 22: This is the name of a mining location on Deadman's flat, on the now famous Pittsburg lode. The owners are about to open it up in good shape by a tunnel, which in its extreme length—300 feet—will give them 220 ft of back. 300 ft in, however, they expect to get the ledge and pay ore.

PLACER.

DURCH FLAT AND GOLD RUN.—Placer Herald, May 22: Both places the large hydraulic mines are nearly all running with full heads, and it is thought that the water will hold out until the last of June. During the recent cool weather, which has been interspersed with showers here and in the valley, there has been considerable snow fallen on the mountains, which, though somewhat unexpected at this season of the year, will serve to materially lengthen the miners' harvest season, and result in an important difference in the year's yield of gold in this county, and doubtless in the whole State, to what was a few weeks ago expected. Altogether the season for hydraulic mining will be almost, if not quite, an average; for though we have had no rush of water this spring from the sudden melting of large deposits of snow, as is usually the case, what we have had has been well distributed, enabling the minor to commence early, and as now seems, to run tolerably late.

The discoverers of the chrome mine have made a new arrangement with the proprietors of the chrome reduction works of Baltimore. The latter take the mine and work it, and pay the former \$3 a ton royalty, for all the ore taken out.

We learn that a mine on the St. Lawrence extension, near Ophir, is now being opened, which gives very favorable indications of being rich and extensive. It is rumored that an English company, with over a million dollars capital, are about to take hold of it, who, it is thought, will put on extensive works.

PLUMAS.

QUARTZ MINE SOLD.—Plumas National, May 22: A few days ago the Wolf Creek company's mine and mill near Greenville, owned by

Butcher, Borge, Lowery & Co., was purchased by Messrs. Lawrence, Bidwell & McIntyre, for the sum of \$8,000. The mine has recently been paying well, and the gentleman purchasing probably got a good bargain.

IRON CLAIM.—Wilburn & Haven, whose claims are situated near Hardscabble, Mohawk valley, have certainly got a big prospect ahead. They took out about \$19,000 last season, and we are credibly informed that, notwithstanding the short run of water, they will do fully as well this year. They picked up a \$200 chip the other day, and it is reported that they pick up \$100 per day in coarse gold. No clean-up has been made yet, but when the "indications" are such as above mentioned, it don't require much judgment to tell what the result will be.

GRANT GRAVEL MINING COMPANY.—This is the name adopted for the extensive gravel claims on the Middle Fork, recently purchased of Gould & Telf by Mr. F. A. Smith, of Sacramento, who buys for a company of Sacramento capitalists. Mr. Smith has been making a thorough examination of the ground and water right, and the indications show that he was pleased with the prospect. The claim will be opened on a creek, directly at the eastern side of Little Long valley. At this point there are splendid advantages in the way of dump, fall for flume, undercurrents, etc., and the solid, clear gravel is over 400 ft in depth. Work on the ditch to bring water to the mine will be commenced about the 1st of June. The ditch will be fourteen miles in length, and will take up all the waters of Cedar creek, and the undrained waters of Hurley creek, Anthony creek and Willow creek, and from there to the Middle Fork. The plan of operations is first to dig a grade 10 ft in width, in which the ditch is to be sunk. It is to be 7 ft on top, 4 ft on bottom and 20 inches deep, and with a grade of one-half inch to the foot. It is calculated that it will be of a capacity of from 3000 to 4000 inches. Work on the ditch will commence at the lower end, so as to get water to the claims as soon as possible. No flume will be used, but in one or two places the water will be conveyed by iron pipes for a short distance. It is probable that the ditching will be done by contract, and as the proprietors intend to finish it this summer, a large force of men will have to be employed. Mr. A. J. Gould has received the appointment of superintendent. We think Mr. Smith showed good judgment in the investment, for the water will cover any amount of gravel, and can be used for 50 years to come in such a way as to make it profitable.

GREENVILLE NOTES.—The Wolf Creek mining company have sold this week to Messrs. Bidwell, Lawrence and McIntyre. The price paid was \$8,000. The new proprietors propose putting up a new mill immediately, and the contract has already been let for the timbers. The Lone Star mill is to be taken down and removed, and steam power attached. All the mills in the neighborhood are doing better than usual. The Greenville mill, twenty-four stamps, will start up in a few days, after a rest of eighteen months. The paying rock recently discovered in the ledge continues to improve in quality as developments are made, and the chances of the Greenville are flattering. Tanner and Wiley are erecting hoisting works on the Cornville ledge, and are preparing for extensive operations soon.

SAN BENITO.

TIN MINE.—Gilroy Advocate, May 22: Mr. C. H. Pratt spent Wednesday night in Gilroy with his son, H. O. Pratt. He has been engaged in prospecting for tin and quicksilver in San Benito county, and says the prospect is encouraging for a good tin mine. A piece of pure tin, the size of one's fist has been found. The place is high up on the mountains and difficult of access. With some grading for five miles it could be reached with a team.

SHASTA.

MAMMO.—Correspondence San Jose Mercury, May 22: Mining prospects are looking up in Shasta county; in fact, the copper mines of Oak Run, the gold mines on Bear creek, and the iron mountain on McCloud river, all in this vicinity, and all recently discovered, are attracting hundreds of adventurous ore seekers to the mineral region. As far as prospecting, the mines in all the above named places offer abundant yields. Coal of superior quality has also been found in the same region, and with this combination of metals, certainly nothing is wanting to facilitate the extraction of the valuable from the invaluable. Mr. Peck, proprietor of the copper mines, recently disposed of a part of his mine not yet prospected, for the sum of \$15,000.

SIERRA.

RICH.—Mountain Messenger, May 22: The rich strike in the Union mine at Gibsonville is a big thing, and promises to stimulate prospecting in that section. It is an entirely new lead that they have found. It has generally been supposed to exist, but never before demonstrated.

DERON.—We understand that the prospects are very good for the building of a large ditch this summer, to convey the water of several lakes in the vicinity of Gold Lake to the northern portion of the county, particularly to the ridge running from Soles' digging to St. Louis. There are thousands of acres of rich mining ground in the limits spoken of, lying idle and unproductive, simply for the want of water. The enterprise of bringing in this ditch will not involve the outlay of over \$150,000, it is indeed, that much. There are no canyons to cross and no expensive tunnels to run. The volume of water obtainable would be large, and

its sale, in a few years, would repay the outlay and good interest thereon.

BIO STRIKE AT GIBSONVILLE.—"Sheep," the La Porte mail carrier, informs us that the Union company, whose claims are located back of Gibsonville, have recently struck it rich, and the best part is, it proves the existence of the big blue lead under the main ridge, and will cause the owners of the adjoining claims to drive ahead their works, with a certainty of being rewarded for their toil. The Union company washed up fifty-three ounces from 200 car loads. There are sixteen shares in the claim, and the owners are jubilant, feeling certain of a fortune. The chances are now favorable for Gibsonville to regain all its lost glory and come back to the lively times of twenty years ago. The owners in the Union are entitled to credit for their perseverance, having run their main tunnel over 3,000 feet, and that, too, without being positive that they would get pay. We hope the strike may make rich men of all of them.

TUOLUMNE.

THE GAZELLE.—Union Democrat, May 22: We are informed that very good ore has recently been found in this once famous mine. A vast amount of money has been made here the past few years without adequate returns, but patience and perseverance seem about to be rewarded.

ALABAMA.—Tuloume Independent, May 22: The Alabama mine has passed into the hands of an incorporated company, under the title of Consolidated Alabama gold and silver mining company. It is their intention to work the mine on a large scale. The company are now engaged erecting hoisting works, and contemplating running a tunnel to their mill, and say that within a year they will be taking out of the mine one hundred tons of rock per day, which (the mine opened) they can extract and mill for less than \$2 a ton. Cowles and Johnston are putting up one of their patent giant quartz mills. They are confident that they can crush fifty tons of hard rock, through a sixty screen per twenty-four hours.

OMEGA, TABLE MOUNTAIN.—The Omega gravel mine is five miles above the "Rough and Ready." E. L. H. Watt has again taken hold of the above claim with his wonted vim as superintendent, and is pushing the work with night and day shifts to intersect with the Alpha at the line of their claim. At this point, Superintendent Collins, of the Alpha, has a forty foot breast of gravel with ledge pitching. Considerable pieces of heavy, black gold, etc., (indicating the old Caldwell channel), weighing eleven, thirteen and twenty-one dollars, were found. This character of gold does not amalgamate, but nevertheless, on account of its great heft, finds its way and nestles into the riffles of the flume.

Nevada.

WASHOE DISTRICT.

ORION.—Gold Hill News, May 20: Daily yield, 150 tons of ore. This ore is being mostly extracted from the 1455-ft level. The ore stopes are all looking well and are yielding the usual quantity of good ore. Three mills are now running steadily on ore from the mine, and others will be added as soon as they can be obtained. The northeast winze has reached the 1600-ft level, and the bottom has been connected by a drift with the prospecting works at the bottom of the north winze, thus securing a fine circulation of pure air, and greatly facilitating the operations in that portion of the mine. The northeast winze passed the entire distance from the 1455 to the 1600-ft level through good milling ore, the body of ore at the bottom being over 100 ft in width. The winze below the 1600-ft level, being sunk with the inclination of the ledge, is down 45 ft, the bottom still in good milling ore. The east drifts from the main shaft, on both the 1500 and 1600-ft levels are being pushed rapidly ahead, and will soon reach the main ledge. Cross-cut No. 3 on the 1700-ft level is being pushed rapidly ahead toward the ore vein, and it is the intention, in a day or two more, to start also cross-cuts Nos. 2 and 4 on the same level. The erection of the new incline machinery is making favorable progress.

FLORIDA.—The station at the 400-ft level is well opened, and the drift started west for the ledge. It is in to-day about 10 ft, and will have something over 100 ft to run in order to reach the ledge.

UTAH.—All the men that can be worked to advantage are employed in grading, laying the foundations and in the erection of the new machinery, and new hoisting works building.

BAVAGE.—The new incline machinery is all working finely. Sinking the main incline is again making rapid progress, the rock in the bottom blasting out finely.

CALIFORNIA.—The cross-cuts on the 1500-ft level are all being forwarded with all the energy possible, there being no change of importance in any of them since our last report. The lateral drift to connect cross-cuts Nos. 3 and 4, on the 1500-ft level, is steadily advancing, the face still in rich ore.

BALTIMORE AND AMERICAN FLAT.—Sinking the main shaft is again making rapid progress. On the 750-ft level, the north cross-cuts have developed a body of fine compact quartz and low-grade ore 30 ft in width, of a very promising character. This development is an entirely new and very important feature, as no such body of quartz and ore has ever been found before so far to the northward.

CONSOLIDATED VIRGINIA.—Daily yield, 400

tons of ore. The ore breasts are all yielding richly as usual, and show no signs whatever of giving out. The mills are all steadily running, and the yield for this month will undoubtedly be as great as that of the month of April. The joint east cross-cut on the California line is steadily proving a much greater extent of ore in that portion of the mine than was expected.

SERRA NEVADA.—The rock in the bottom of the old shaft is much harder. The face of the main east drift on the 700-ft level is still in ledge material. Sinking the new shaft is also making fine progress. The foundations for the new and powerful air compressor are completed.

EUROPA.—The new three-compartment working shaft is well timbered and completed to the depth of 25 ft. The necessary carpenter and blacksmith shops have been erected, and the timbers are beginning to arrive for the erection of the new hoisting works building.

YELLOW JACKET.—Work is being pushed at all points on the 1740-ft level with all the vigor possible. The north drift is being especially crowded forward to make a connection with the main south drift on the 2000-ft level of the Imperial for air purposes.

PAUL SHERIDAN.—The face of the main west drift is to-day in porphyry, quartz and clay, being considerably softer material than that heretofore met with.

SUTRO.—A survey has been made during the week which shows the ledge to be over 50 ft distant from the face of the tunnel yet, the distance to run being greater than was anticipated.

IMPERIAL EMPIRE.—The main south drift on the 2000-ft level is being steadily pressed forward to connect with the north drift from the Yellow Jacket on the same level.

CROWN POINT.—Daily yield, 550 tons of ore, keeping the mills all steadily running. The ore breasts show no change for the week past. Prospecting on the 1600-ft level has made no new developments of importance. Work will be resumed in a day or two more at the 1700-ft station.

ORIGINAL GOLD HILL.—Cross-cut No. 2, south, at the 340-ft level, is in fair grade ore, and shows improvement as further progress is made into the ore body.

HALE & NORCROSS.—The west cross-cut on the 2100-ft level is still pressed vigorously ahead, the face in ledge material.

GOULD & CURRY.—The north drift on the 1700-ft level is being driven vigorously ahead to connect with the Best & Belcher south drift.

BULLION.—The ledge developments on the 1400-ft level of the Imperial shaft continue to improve as the work advances, with every indication of the finding of a pay mine.

LADY BAYAN.—The main west drift on the 380-ft level has penetrated the ledge for a distance of 30 ft, which at this point is solid white quartz, of the most encouraging character, carrying spots of fine ore. The red, oxidized ores, found on the levels above, have apparently all disappeared, and the ledge is assuming all the essential characteristics of the Comstock. The south drift on this level has not yet reached the ore vein. The face of the main south drift on the 250-ft level is still in ore of a good quality, as is also that of the south drift on the 170-ft level. The main south drift, on the 80-ft level has developed a fine body of milling ore, further to the southward than any heretofore found, one that promises a lasting development of much value.

BELCHER.—Daily yield, 500 tons of ore. The ore for the past week shows a slight improvement in quality, and there seems no prospect whatever of a diminution of the yield. Work at all points on the 1500-ft level is again being vigorously prosecuted.

BUCKETT.—The prospects of the mine are of such an encouraging character that it has been decided to erect more powerful machinery for its development. The new machinery is to be of sufficient power to sink the shaft to a depth of 1500 or 2000 ft.

CHOLLAR-POSSL.—Sinking the main incline is making fair progress. The south drift on the 1250-ft level is also making rapid progress, the face in soft porphyry. Grading for the new combination shaft is making all the progress possible.

NAGARA.—Sinking the main shaft is making splendid progress, the ore vein at the bottom showing a steady improvement as greater depth is attained.

AMAZON.—The cross-cut now being run to intercept the ledge at the 100 ft station is in 20 ft, and will soon reach the ore vein. This portion of the Comstock ledge is beginning to attract considerable attention, and it is confidently expected that pay ore will be found in this cross-cut.

JUSTICE.—The drift south at the 800-ft level is softer and more favorable vein material than heretofore.

SUCOON.—Preparations are being made to track ore from the slopes opened in the drifts in from the bottom of the shaft, east of the hill.

BEST & BELCHER.—The rock in the face of the south drift from the bottom of the winze at the 1700-ft level continues extremely hard. **JACOB LITTLE CONS.**—Good ore continues to meet with in the northeast drift, some of which gives high assays.

NORTH SAN FRANCISCO.—Sinking the main shaft is making the usual steady and favorable progress, the rock in the bottom working freely.

WALLS-PARCO.—Three shifts of hands, working night and day, are making lively work in sinking the shaft, and drifting at the 150-ft

level. Very promising and favorable material is met with at both points.

OVERMAN.—Draining the water from the bottom of the shaft is making favorable headway. No work is yet being done on the 900-ft level.

MEXICAN.—The winze below the 1465-ft level is down 12 ft in quartz and ore of a highly encouraging character.

Arizona.

MINING ITEMS.—*Arizona Citizen*, May 15: The Silver King, Pinal mountains, is now down nine ft and richer than ever.

Welch's new discovery, five miles north of the "King" is said to be half silver.

Florence, the county east of Pinal county, depopulated on account of the above information, only four persons remaining to take care of the women and children.

"Pike" came in Thursday from the mountains with the richest lot of specimens ever brought here, and reports rich veins in the different parts of the Pinal.

Parties who have visited the Quacharty pronounce it a true and rich mine and negotiations are now pending for its purchase. In the hands of parties able to conduct operations on a large scale there is no question but these valuable mines would be made to produce immensely.

The Young America copper mine is beginning to receive returns from shipments made to California and receive over \$100 per ton profit. This is claimed to be the most valuable copper mine on the globe.

Colorado.

BULLION.—*Georgetown Miner*, May 15: The silver bullion shipped by the Stewart silver reducing company for the two weeks ending May 14th, amounted to \$15,948. The Juda & Crosby reduction works shipped during same time \$3,645.

LOW GRADE ORES.—There has never been a time, in this mining camp, when more interest was manifested in the great veins carrying low grade ores, than at present. The immense veins that have been for years neglected will soon be paying tribute to industry and enterprise. It only remained for the time to arrive when enterprises, guided by experience, should construct dressing works calculated to condense the wealth locked up in these great "ore channels," to make them yield the wealth they have so long securely held locked up in the chambers of the hills, and that time is at hand.

GENEVA.—Through the efforts of James Teal, in England, a strong company has been organized, which has bought and will work a mine in Geneva district. As soon as the snow melts on the Range, Mr. Teal will commence operations.

From Downieville and Mill City comes encouraging news. Several mines have lately been discovered that show large bodies of mineral, and are being rapidly developed. Old neglected claims, which litigation has paralyzed, have been re-located, and are receiving due attention, while our high prices for ore have stimulated the owners of many mines to fresh efforts.

Idaho.

OTU MINES.—*Owyhee Avalanche*, May 22: Reports of the condition and prospects of the mine in this vicinity are quite encouraging, and there is every indication that the season will be one of marked activity and prosperity. The developments in many of the leading mines are of the most hopeful character, and fully justify our recent predictions concerning the extent of the yield the coming summer.

GOLDEN CHARIOT.—The developments within the past week are the most promising of any that have ever yet come to light in this or any other section of the Pacific slope. The samples of the new ores which are now on exhibition at the office of Superintendent Keown fully justify this statement. They are from a ledge of the Chariot which has long been supposed to have an existence, and which, both as regards the quality and quantity of the ore, is a remarkably important development. The ledge was discovered from the old workings on the second level, following a vein running west of south, which led into the main vein 30 feet west, parallel with the old vein of the Chariot. It bears characteristics of the true dip, the ore being surpassingly rich, and in the best walls of the mine, demonstrating that the ledge of the mine has now been reached. By cutting west on different levels, a new mine of untold wealth presents itself.

SOUTH CHARIOT.—The 10th level drift is coming into good ore. The 9th level drift, north and south, are in good ore, that in the south being no doubt a portion of the rich chimney recently opened in the lower levels of the Mahogany mine, and the superintendent thinks that the same class of ore will be encountered on the 10th and 11th levels, which will be reached in the course of two months. The prospects of the mine are steadily improving.

MAHOGANY.—Superintendent Corey, under date of the 19th inst., reports that large bodies of high grade ore are being opened on the 9th and 10th levels. They continue to widen and lengthen as they are opened. Milling will be commenced about the 1st of June, when it is anticipated that the results will come up to the most sanguine expectations of all interested. All work at the mine is in progress as usual.

RED JACKET.—The developments in this mine for the past week have been very satisfactory.

WAB EAGLE.—This mine is said to be looking better throughout its entire work than it has ever looked before. The New York mill is kept

constantly at work on its ore, of which there is a large quantity on hand at the mine, and is now being hauled to the mill.

Montana.

MINING ITEMS.—*Helena Independent*, May 8: Silver Star, in Madison county, expects to have three mills running ere long. Hoisting works will be put on the Green Campbell lode, and Mr. Everett will give his attention to the business of the company this season.

Wadams & Shenon, of Bannack, have enough ore on to run their mills through the summer.

Bragg & Peck have been working all winter on the Del Norte lode, Blaine Wing district, taking out rich ore.

At Vipond, Spott & Co., Collins, Patton, Sautorn, Wunderlich, Bubecker, Wilber and others, are taking out good ore, which they hope to convert into money this summer. The ore assays from \$50 to \$200 per ton, and can be reduced here at considerable profit.

At Divide, Mr. Elser's reverberatory smelter has more than paid for itself, though only operated for a short time before the cold snap, and is now running with a splendid prospect ahead. All the material for building, lining and hearth was found near the site, and the peculiarities of the ores in camps near by are such as to enable the works to run steadily at a profit to proprietor and mine owners. Wunderlich and Elser are to be congratulated, on their success.

Oregon.

CLEAN-UP.—*Bedrock Democrat*, May 19: Powers & Co., of Rye valley, made a clean-up from a short run in their placer claims, and had the proceeds run into a bar at the assay office of J. W. Virtue on last Monday. The bar was worth \$2500. We understand the claims are yielding and prospecting better than ever before.

VIRTUE.—(Telegram) Bullion shipped on the 25th, \$11,000.

SALE.—*Coos Bay Record*, May 19: It is reported that the Eagle mining company has sold its black sand claim. The terms are not made public as yet.

Industrial Items.

THE LOS ANGELES EXPRESS of the 20th says: The car for the prismoidal railway came down on the *Orizaba*. As soon as it reaches the city it will be tried on the section of track 200 feet long which has been prepared for the experiment, and if the test proves satisfactory the work will be begun at once on several prismoidal roads. No doubt is entertained but that the experiment will prove a success.

REPORTS are to the effect that the Carson river is lower than ever before at this season of the year. Even the wood drivers are in despair, and the mill men are fast joining them. The wood-drive comes down so slowly that great difficulty is apprehended in getting the full supply.

MESSES. Clark & Banghman, a firm from Quincy, Illinois, will start an organ manufactory in this State, and although they made their sample instruments in Oakland, the Petaluma *Argus* thinks they will establish their manufactory permanently in Petaluma.

THE ALASKA COMMERCIAL company of this city has entered into a contract with Cramp & Sons, whose works are on the Delaware river, by which the latter will construct a first-class thousand ton steamer for the Northern trade.

THE LAST LEGISLATURE of Arizona passed an act awarding a premium of \$5,000 for the first artesian water obtained at a greater depth than 500 feet, or \$3,000 for artesian water obtained at a less depth, in that Territory.

THE DEMOCRAT says Santa Rosa has now an opportunity to erect a woolen mill. H. Bale & Son, of Petersburg, Illinois, are willing to bring their mill to California and take one-third the capital stock.

THE LOS ANGELES PAPERS think the oil wells of that section will some day rival those of Venango county, Pennsylvania, or at least yield a better profit to the producer.

THE SALT LAKE HERALD says that the amount which the English parties are to have for constructing the Portland, Dalles and Salt Lake railroad is \$28,000 per mile.

WORKMEN are engaged in putting machinery in place in the Petaluma woolen mill, and if no looked for event transpires, the factory will be in operation within two weeks.

THE MACHINERY of the California broom factory has been moved to South Vallejo, and the manufacture of brooms will hereafter be conducted there.

VISALLA expects to have gas works; the illuminating property being derived from crude petroleum.

A MRS. BLACKBURN, of Merced, is supplying the community with rag carpet woven by herself.

THE PETALUMA CHEESE-FACTORY will make 150 tons of cheese this year.

THE VIRGINIA, NEVADA, CHRONICLE has again changed hands. Mr. D. E. McCarthy, formerly of the San Francisco *Chronicle*, is now the sole proprietor.

ANOTHER explosion at the Hazard powder works. Three widows mourn the fatality which leaves their children fatherless.

Hints on the Washoe Process.

(Continued from last week.)

The Crushing In the Battery, Continued.

This is not a very heavy loss, and, besides, most of this gold can be collected in the slime yard, while of the remainder much is so fine that it is doubtful if quicksilver in the battery would catch it. The saving, then, is very small, if there be any, on ordinary ores. But, on the other hand, it is not practicable to use quicksilver without a mechanical loss; and the quicksilver being more or less charged with gold, the loss of each as is not gathered and united involves more or less gold also. Every casting, such as a shoe or die, in the battery is full of flaws and blow-holes. Hard gold amalgam collects in these, and in spite of the most careful picking and breaking, (to say nothing of the occasional carelessness of workmen,) every shoe and die, when used up and thrown away, contains a very considerable amount of gold amalgam. The cracks in the wooden troughs get filled with gold amalgam; the settling vats or tanks have their seams, after a long time, caked with it; and in the slime yards will be found some of the gold partially amalgamated. Why should we, then, amalgamate in the battery, when we know that, except a very small and doubtful saving from the gold of the slimes, (which seems offset by the mechanical losses above alluded to,) all this gold is saved just as thoroughly in the cast-iron pans? The pulp is not concentrated before entering the pans. If it underwent such a process, of course there would be additional chance of loss of fine gold, an additional argument for amalgamation in battery. It will be perceived that the reasoning just given applies, therefore, to the Washoe process, and not necessarily to gold mills where pans are not used. Yet even then the practice of amalgamation in battery is not universal nor, indeed, the best.

The Settling in the Vats or Tanks.

There should be as many tanks as possible, in order to settle the maximum quantity of slimes inside the mill; and the system should be so arranged that as each tank is emptied of sand, the escape or waste water can be returned into it. Each tank thus becomes in turn the final one of the series, and receives all the water after settling through all the other tanks. There should never be more than three tanks full of sand; the remainder, even if there are twenty of them, should be used for the settling of the slimes in the water.

Each tankful of sand must be settled or prepared so that the contents can be easily handled with the shovels, and charged into the car for transfer to the pans. In other words, the superfluous water must be removed; and this should be done without allowing the slimes to pass out of the tank, only to be carried by the current through the other tanks, and thus be driven ahead constantly toward the escape. Hence, it is as well not to settle the sand at all till the tank is full of sand. Then let the apout be turned into the next tank, and put in the plugs of the full one, thus cutting off communication and isolating this tank, after which the sand may be settled with crowbar and shovel, and the water haled out.

The ore is now in the shape of a wet, coarse sand, called pulp, containing, according to its original nature and the character of the crushing, more or less slime, (locally called "slim.") So far the process has been entirely mechanical, and the efficiency which has been achieved in this part of the treatment is measured by mechanical tests. The result with the arrangements above described may be summarized as follows: forty-eight tons of hard ore, crushed with twenty stamps of 650 pounds, dropping eight and a half inches ninety-five times a minute; the ore from the breaker being fine, and No. 4 screen being used. This is, per twenty-four hours, two and four-tenths tons per stamp, or 1.39 tons per horse-power developed.

The Treatment of the Pulp in the Pans.

There are many different styles of pans. I prefer the Wheeler for a small pan, and the Stevenson mold-board pan where a large one is desired. The general principle is the same. The ore is to be heated and ground thoroughly to an impalpable substance; an active motion or circulation given to the pulp; the silver thoroughly reduced; the gold thoroughly brightened and cleaned from its occasional intimate mechanical mixture with foreign minerals; and finally, the gold and silver are to be as entirely as possible taken up by the quicksilver. Chemicals are used, partly to reduce the ore, partly to save quicksilver and keep it clean, and partly to reduce by cheaper means what would otherwise be reduced at the expense of the quicksilver.

(To be Continued.)

The following portion of the programme for the celebration of the Centennial of our Independence has already been perfected: President of the day, the President of the United States; Orators, Charles Francis Adams of Massachusetts, and Lucius Q. C. Lamar, of Mississippi; Poet, H. W. Longfellow, of Massachusetts; Reader of the Declaration of Independence, Ralph Waldo Emerson, of Massachusetts; Grand Marshal, General W. T. Sherman; Master of Ceremonies, General Joe. E. Johnston.

The Kern County *Courier* has changed hands, and the last issue presents an improved appearance.

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Fourteenth Lecture Delivered before the University of California College of Agriculture, on Monday, February 8th, by Prof. C. E. BRSEY.

(Continued from our last issue.)

Ornamental Plants.

In the Virginia creeper, *Ampelopsis quinquefolia*, found east of the Rocky Mountains, we get one of the finest deciduous vines that we have.

In a little order, very nearly allied to the vine family, the order *Meliaceae*, a small group of two hundred species, tropical shrubs and trees, we find the mahogany tree; and as it is a tree of great commercial value, it is worthy of special notice. This tree is the *Swietenia mahoganii*, found in Jamaica and tropical America, a large tree with ash-like leaves. Very frequently they can get the trunks large enough so that they will square from four to five feet.

Jamaica cedar, which also comes into this market from the island of Jamaica, is *Cedrela odorata*, a large tree resembling mahogany. The only thing I need mention here is, that it is not a cedar. It stands nearer to the maples than the other trees. *C. australis*, found here also in the market, is a good, large tree, sometimes ten feet in diameter, yielding very valuable wood. Satin wood, of which you can see specimens at the furniture shops, is *Chloroxylon*, (the species I don't know) from the East Indies; and then again in another allied family, a very small one, of some fifty species, we get what is called zehra wood, a reddish brown wood, with peculiar zehra-like markings upon it, (*Omphalobium Lambertii*.)

It is a good sized tree found in South America. The wood is fine. These are of great importance to furniture makers especially. We pass now to another family, the

Flax Family,

Linaceae, containing about one hundred species of herbaceous or small, shrubby plants. They are usually rather a natural species, and are found mostly in temperate regions.

The only plant of importance to us is the common flax, *Linum usitatissimum*, which has been grown for nobody knows how long. We find the remains of linen fabrics among the remains of the pre-historic lake dwellings, in Switzerland. You know that within the last few years discoveries have been made about those lakes, archaeologists finding that some people lived there long before the period of which history gives any account. Among other discoveries are these remains of linen fabrics, proving the use of linen to have been known at a very ancient period.

Mummy Cloths

Are found in a good many cases to be made of linen also. The plant, now grown almost everywhere in the temperate climates, seems to be peculiarly well adapted to all climates, can be grown in temperate climates as well as down next to the tropics; it is accordingly grown very largely. Its fiber, which belongs to the outer portions of the stem, is separated from the remainder simply by breaking it up and then by carefully combing out the bark and woody portions.

In order to facilitate this it is subjected to a sort of rotting process, either artificial or in the open air, and is allowed to lie for some time, and then it is broken up.

Within the last few years some French chemists have been experimenting on the flax fiber, with a view to making it finer, as all our fiber is somewhat coarse. These chemists, knowing very well the nature of the fiber, that it is simply a hollow tube, tried soaking it in an acid solution, then washed this out, then used a certain alkaline solution, then soaked it in a solution of a carbonate—some carbonate which had a great deal of carbonic acid in it, etc., the object being to burst open the fibers. The result was that the flax was very much finer than it otherwise would have been. In that way the "Cottonized Flax,"

As it is termed, was made. It was supposed at one time it would be brought into general use, but for some reason it is not used as much as perhaps it deserves to be. In some countries where flax is grown, the seeds are gathered and used for the manufacture of oil, which is the linseed oil so largely used in all paints, and the crushed seeds are manufactured into what is called cake meal, used for feeding cattle.

Passing to the next group, the tea family, the order *Camelliaceae*, embraces trees or shrubs, mostly of the better parts of the globe—in fact none are to be found in the colder climates.

About 130 species are known, and of these the plant of most importance is the tea plant, *Thea Chinensis*. (Fig. 2.) a small sized tree, growing ten or fifteen feet in height and supposed to be a native of Assam; it is a little country just north of the bay of Bengal; and from this country it was carried eastward into China and Japan. It is now grown largely throughout China, Japan and to some extent in some other countries with a climate somewhat similar. In your botanies you will probably find that instead of one species given for the tea tree you will have two species. This comes from a mistake made by the earlier botanists. We have in the market what is called green and black tea. Botanists first thought that these were derived from different plants. Later investigations show that they are derived from the same species. In procuring tea, the pro-

cess is this: simply gathering the leaves, and more or less rapidly drying of them. If they are dried very rapidly, so that no fermentation takes place, the product is green tea. If they are dried slowly, so that fermentation begins, the product is a black tea; and there you get the essential difference. There is another element that may come in to determine the greenness or the blackness of the tea. If the earliest leaves are taken, the first growth of small leaves, it is much easier to make green tea than if the old ones are taken. So that they do not need to be as careful with the early as with the later growth, to determine whether the tea shall be green or black, while from old leaves they cannot make anything but the black tea. Now, whether green tea is better because it has not been partially fermented, or not, I cannot say. Possibly it is, my taste would say that it was. [Student.—"I have heard, Professor, that green tea was the tea leaves dried on copper, and that there was an acid came out of the leaves, as it were, which gave color to the leaves." That statement has been made, and if you attempt to look up the matter thoroughly, you will find that the observers make all sorts of statements. Now, in some books you will find that there is one variety of green and another variety of black. That, we know to be a misstatement. Others state that the difference is due to packing. That is, some observers, seeing the manner in which the natives separate the young leaves from the old, have been led to this conclusion. Others give another story, saying it was entirely due to manipulation. The fact is this, that all these might have something to do with the determining of the variety of the tea. Some very poisonous coloring matter has been used, so that a great many years ago many people stopped using green tea on that account; but the facts are as I have essentially given them. Peculiar varieties are obtained by selection and manipulation; and under the head of manipulation, of course, you will get the use of coppers and all that. They are results of different methods of growing, or, just simply slight differences. Of course, you understand, only a slight difference would give another variety. Now,

Teas Can be Grown in California

And in very many States east of the Missis-

Fig. 2. Leaves and Flowers of Tea Plant. This has been tried here, but labor is so costly we cannot manipulate it, cannot roll it, cannot gather it leaf by leaf; and you see that you cannot go and take a stem and take all the leaves. They have to be carefully picked.

So they found they could not produce tea after it was actually grown, and so, of course, it was given up.

Now, if our ingenious mechanics here can give us some machines which will do the work which has hitherto been done just by hand—all of our best teas have been rolled leaf by leaf—if that work

Can be Done by Machines

There is no reason in the world why we cannot grow all the tea wanted on this coast; also, all wanted on the Atlantic coast. There is a curious thing about this matter of tea. The demand is wonderful—almost beyond belief. We brought into this port here, last year, more than fourteen million pounds; of course a considerable amount of it was reshipped, sent across the continent; and yet, about a hundred years ago the first tea was taken to England; about a hundred years ago it was first taken to Europe and introduced there, and yet, in this time we have so changed our habits that the demand is such an immense one as I have just given you. Taking the statistics for the past few years I find that the proportion of value is about this: Fourteen million pounds of tea are valued at

About Five Million Dollars

When brought here. Now you see the immense profit that there must be in it right here at home. The more you study up this matter of tea the more you will be astonished, and you will find yourself especially astonished at the cheapness of it where it is produced. At the present time you can buy it for almost nothing. And then, when you consider the amount of labor given to it, and the transporting of it hundreds and thousands of miles, the only wonder is that we do not have to pay more for it than we do.

I will briefly call your attention to the remaining matter I have on the board, because I cannot spend any more time on this subject of economic botany. I have upon the board the mallow family, order *Malvaceae*.

It is made up of herbs, shrubs and trees, including about 1,000 species. It has some representatives in the temperate regions, but they

grow mostly in the tropics. Under these is the most important plant in the world, the cotton plant, *Gossypium herbaceum*, growing in places about five or six feet in height. It produces cotton which is made up of little fibers. It is found native in the East, in the Asiatic countries and in the tombs of the Incas; in Central America and in Mexico we find the remains of cotton fabrics. The question is, how they got there. It is cultivated now almost all over the globe, and very largely in the United States. It is biennial, triennial, or annual, just as it is treated. The one that we have specimens of here is the species called *herbaceum*, and is the one mostly grown. They plant it in the East about as they plant Indian corn, in March or April, and pick it along in the latter part of the year. In the Mississippi valley it yields 357 pounds per acre, that is about a bale per acre. In 1858, 3,000,000 bales were produced there. Now, to illustrate the dependence that agricultural labors have upon mechanical inventions, I simply will call your attention to the invention of the cotton gin. In 1793 Whitney invented a machine for separating the seeds from the cotton fiber. If you try to hand to do that, you will find the process tedious. Before he invented that machine it took a man about a day to get out a pound of cotton. By his machine, after it was improved a little, a man was able to separate 300 pounds, so that it increased one man's usefulness just three hundred fold. The next thing that is needed, and the thing that will make it possible to grow cotton in California, is a

Machine to Pick the Cotton.

It will not do to cut the whole growth down and take it to the barn or stack to be afterwards separated. The field must be gone over time after time, and if when the pods burst open, rain comes, there is danger of their being spoiled. The need now is, for some Eli Whitney to get up, or invent, something by which this can be easily gathered. Its culture in California will have to be deferred until that time; you cannot do the work cheap enough, unless you can train Chinamen. But I am told after a time they become as well accustomed to demand high wages as other people.

This, (alluding to specimens,) is the California cotton, very good, too.

Under the poppy family, *Papaveraceae*, we have a hundred species, milky, narcotic plants, including the one of greatest importance, the opium plant, *Papaver somniferum* of Asia Minor and India.

Under the magnolia family, we get trees again, and the most important is this great soft wood tree of the east, the tulip tree; or white wood, or yellow poplar (*Liriodendron tulipifera*), the best soft wood, perhaps, in the world; grown only in the United States, east of the Mississippi river.

Wood and Iron in Building.

This is much more nearly the age of iron than any which has preceded it. The age of wood is passing. In every part of the world, the demand for timber is so great, that forests are being cut down at a rate which threatens to leave the earth's surface in a few years desolate and bare. Metal must become an object of increasing use, and iron, as the strongest and cheapest of metals, will be most generally employed. Ship-building has already taken a very decided turn in that direction, which is due in a great measure to economy in the use of metal. In houses and public buildings iron is used for many purposes which were at one time entirely occupied by wood. In this country the plentifulness of timber has been a great source of injury rather than of benefit. We have used it in many ways wasteful and dangerous, and the fact that more property is destroyed by fire in the United States than in any other country in the world is to be attributed to the reckless use of wood in our buildings. But we have already reached that boundary of this extravagance.

In the next place, it is a matter of complaint that the supply is lessening with such rapidity that it will be absolutely necessary not only to create legal obstructions to the course of extravagance, but to encourage the planting of trees, in the hope of producing wood for future advantage. In building, although the use of timber continues, it is by no means as common as it was a few years ago. The frame house is a novelty in the cities. Brick and stone replace it. The shingle roof is becoming scarcer, iron, and tinued iron, and various roofing compositions have superseded the shingle. Some of the latter are not improvements in the line of inflammability, but they show that the cypress shingle is becoming scarcer, and necessity requires the use of other materials. The diminution in the use of wood for building purposes will reduce the risks from fires. Buildings of stone, brick and iron, in which wood is employed for no purpose, would be practically fire-proof, and stand in the way of those destructive conflagrations which sweep through our great cities, causing tremendous destruction of valuable property. The insurance companies have it in their power to aid in a great work by offering policies at reduced rates for fire-proof, or nearly fire proof houses. This might be done with great advantage. The problem is one of necessity, a solution of which can not much longer be deferred.—*American Builder*.

Antique and Walnut Furniture Finished in Oil or Wax.

This style of furniture is very effective if the design is appropriate. The French call it the style Renaissance, or revival of old style. In removing ancient buildings there were many fine sculptured oak panels (copies of those found in the Vatican at Rome, and designed by Raphael, Michael Angelo, and other celebrated artists,) the wood of which, from age, had become very dark. They were adapted to book-cases, cabinets, etc., in connection with new oak. The new wood was dyed with nutgalls to match the panels, and all finished in oil or wax. This was to bring the carving out in bold relief, as varnishing or bright polish destroys the effect.

The color of American walnut, when oiled, approaches very near the color of dark old oak, and finishes much finer. American walnut requires the grain to be well filled with a composition to resist the action of the heat of our dwellings, and mere oiling will not do, as it leaves the pores of the wood so open that it absorbs the heat; in a room at a temperature of seventy-five degrees the oiled walnut will absorb the heat to within five degrees of that of the room, whilst varnished oak will reflect the heat, and will not reach over forty-five to fifty degrees. It is therefore important to have wood well seasoned and the grain filled with shellac or other material to prevent shrinkage.

If the furniture is well varnished it is easily renovated by rubbing with a rag moistened with turpentine and linseed oil, in equal parts. If not properly finished and the dust collects in the pores of the wood so much that it will not wipe off, the application of oil and turpentine will restore the color, and a very light coating of shellac will protect it in a great measure. If nothing but oil is in the wood, it is best to have a cabinet maker finish it properly, otherwise it must be oiled every time it looks rusty. Linseed oil hardens wood, and well made walnut work, finished with it and shellac, will in a few years become polished almost like bronze. The French use this finish only on sculptured work or on very fine root walnut veneers in connection with ebony moldings. They do not use it as a finish for plain furniture, but use a polish made of gum shellac and alcohol, applied by manipulation, using a wooden pad, moistened with polish, enclosed in a soft old linen rag. It makes a fine soft finish and wears well in a humid climate; but evaporates soon in ours. Wax is used on walnut when the natural color is to be preserved, and in connection with ebony moldings, polished finely, the effect is beautiful. This style is the favorite in Europe, and will no doubt become popular here.—*The Cabinet Maker*.

THE EUROPEAN larch has such a fine grain, and is so exempt from cracking that painters use it for their pallets and to paint pictures on; for this purpose it was used by the ancients; several of Raphael's paintings are on larch wood. Its beautiful color and capability of high polish adapt it well for cabinet work.

The late Duke of Athol, (the great larch planter,) several years before his death had boards of it sawn to make his coffin. At his death they were sent to a cabinet maker to be worked for that purpose, and in them he was buried. While lying in state, and the people passed to view the body, their persons were reflected by its lustrous polish.

REMOVING PAINT FROM WINDOWS.—Inexperienced painters, when painting window-casings and sashes, frequently spatter paint in minute dots over the surface of many of the panes, where it is left until it becomes dry and hard. Neat workmen always have a clean cloth or sponge, which is dipped in a little spirits of turpentine, and the paint is rubbed off before it has dried. After the paint has become dry and hard, strong soap-suds will not remove it without a vast deal of hard rubbing. The most economical way to remove dry paint from the panes is to make a small swab having a handle some eight inches long, dip it in a little diluted oxalic acid, and rub off the paint with the swab.

THE ELDER.—It has been said that the elder tree supplies us with the softest kind of timber, as well as that which is the most easily split; and yet experience shows us that in the water it is the most enduring of all. But, soft as it is, it sustains the greater part of the city of Venice, for the massive buildings stand upon piles of elder which have been for ages sunk in the sea. No other timber could have endured so long under the great harden and the rotting power of the water, and formed such a sure and lasting foundation for that noble city.

To paint on zinc, make a weak solution of sulphate of copper and wash the zinc with it, then wash it afterwards with hot water. When dry, it will take any paint you wish to lay on. Mix your colors with turpentine, and not with oil, adding a little good varnish, that the colors may dry a dead face. When completed, varnish with good copal, your paint will not blister, and the colors will be bright and durable.

ENGLISH IRON IN THE UNITED STATES.—Last year no English railroad iron was brought into the United States, except on the Pacific coast. Some Bessemer steel rails were also imported under the name of iron. In 1873 English rails declined in the United States from \$73 to \$58 per ton. In December, 1874, they had sunk to \$49 or \$50.

USEFUL INFORMATION.

The Fahrenheit Thermometer.

"Zero," on the common thermometer, like the fanciful names of the constellations, is a curious instance of the way wise men's errors are made immortal by becoming popular. It may be worth while to say that the word itself comes to us through the Spanish from the Arabic, and means empty, hence nothing. In expressions like "90° Fahr.," the abbreviation Fahr. stands for Fahrheits, a Prussian merchant of Dantzic, on the shores of the Baltic sea. His full name was Gabriel Daniel Fahrenheit.

From a boy he was a close observer of nature, and when only nineteen years old, in this remarkably cold winter of 1709, he experimented by putting snow and salt together and noticed that it produced a degree of cold equal to the coldest day of that year. As that day was the coldest the oldest inhabitant could remember, Gaeriel was the more struck with the coincidence of his little scientific discovery, and hastily concluded that he had found the lowest degree of temperature known in the world, either natural or artificial. He called that degree zero, and constructed a thermometer, or a rude weather glass, with a scale graduated up from zero to the boiling point, which he numbered 212, and freezing point 32—because, as he thought, mercury contracted the 32d of its volume on being cooled down from the temperature of freezing water to zero; and expanded 180th on being heated from the freezing to the boiling point.

Time showed that this arrangement, instead of being truly scientific, was as arbitrary as the division of the Bible into verses and chapters, and that these two points no more represented the real extremes of temperature than "from Daa to Beere-haba" expresses the exact extremes of Palestine.

But Fahrenheit's thermometer has been widely adopted, with its inconvenient scale; and none thought of any better until his name became an authority, for Fahrenheit finally abandoned trade and gave himself to science. Then hisbit made people cling to the established scale, as habit makes the English cling to the old system of cumbersome fractional money.

Our nation began to use Fahrenheit's thermometer about the middle of the last century, or not far from the time when old style was exchanged for new style in the writing of dates.

The three countries which use Fahrenheit are Holland, England and America. Russia and Germany use Reaumur's thermometer, in which the boiling point is counted 80° above freezing point. France uses the centigrade thermometer, so called because it marks the boiling point 100° from freezing point.

On many accounts the centigrade system is the best, and the triumph of convenience will be attained when zero is made the freezing point, and when the boiling point is put 100 or 1,000° from it, and all the subdivisions are fixed decimally.

If Fahrenheit had done this at first, or even if he had made it one of his many improvements, after the public adopted his error, the luck of opportunity, which was really his, would have secured to his invention the patronage of the world.—*Ex.*

FOREIGN TALENT AS AN AID TO PROGRESS.—Some countries, such as Russia for instance, have always done their best to attract foreign workmen, foreign artists, foreign talent of every sort, conceding special rights and immunities to the valuable colonists whose skill and knowledge silently help to reclaim the natives from barbarism. But for such importations from England, Holland and Germany the great empire of the Czars would not at the accession of Peter the Great have possessed a ship, or a sailor to navigate it, or a foundry for cannon. Some famous old manufactures are now all but extinct in the birthplace of the art. Toledo and Damascus no longer furnish their historic sword-blades to half a world; Florence and Mantua no longer clothe Europe; the Venetian glass has been but artificially revived, for none can obtain the subtle spirit Prosperity to their chariot wheels; and when greed or neglect has brought about the period of decay, it is but a blank prospect that awaits native industry.

HOW TO MAKE OIL LAMPS SAFE.—A great many accidents are happening every day from the use of kerosene. I will tell you a method by which they can be to a great extent prevented, and I hope you will publish it for the benefit of poor people, who are obliged to buy cheap oils. If the body of the lamp is filled with cotton, such as jewelers use to wrap their articles in, after it is stuffed lightly it will receive one-half the quantity of oil which it would if the cotton were not put in. If any accident happens, the oil cannot spill or flow about; but is, as it were, "sopped up" in the cotton, which burns like a fagot, but all in one place.—*Ex.*

TO RENDER PAPER OPAQUE AND AGAIN TRANSPARENT.—It is worth knowing that if one volume of castor oil be dissolved in two or three volumes of spirits of wine it will render paper transparent, and the spirit rapidly evaporating, the paper, in a few minutes, becomes fit for use. A drawing in pencil or in Indian ink can thus be made, and if the paper is placed in spirits of wine, the oil is dissolved out, restoring the paper to its original condition. This is the discovery of Herr Fischer.

GREEN BRONZE ON IRON.—A process for producing a green bronze on iron, devised by Paul Weiskopf, is given by *Dingler's Journal* as follows: One part of sylvate of silver is dissolved in twenty parts of oil of lavender, forming a sort of varnish, which imparts a beautiful and permanent green bronze appearance to cast and wrought iron, sheet iron and wire. The surface to be bronzed is cleaned and dried, but need not be polished. The varnish is thinly applied with a camel's hair brush, and the object heated quickly to 300° Fahr. The proper temperature is indicated when the article shows a bright green color which is even all over it. To produce a bronze drawing, Venetian turpentine or colophonium solution is substituted for part of the lavender oil. It is better to rub up the dry sylvate of silver with resin in a mortar or on a palette, and then add enough lavender oil to make it as thin as ordinary paint. Articles of iron bronzed in this way can afterward be electroplated.

LIQUID PARCHMENT.—According to Dr. Hoffman, a fluid by this name, consisting of gutta-percha softened and soaked in ether, is especially adapted for forming a coating for pictures and cards, it permitting the removal of dirt with a moist rag. Pencil and crayon drawings may be rendered ineffaceable by sprinkling with this liquid by means of an atomizer, an exceedingly delicate film remaining on the evaporation of the ether.

MAKING BRITTLE GOLD STRONG.—Gold is sometimes so brittle that the jeweler can not well work it; this is probably due to phosphorus, which, being no metal, is of course not detected in the assay. The remedy is to pass chlorine gas through the molten gold, by which treatment most of the gold which had otherwise to be set aside as unfit for certain kinds of work, can be redeemed.

CEMENT TO UNITE BRASS AND WOOD.—The *English Mechanic* says the best cement for this purpose is a glue composed of best gelatine one part, glacial acetic acid one part. Soak the gelatine in cold water until it has swollen up and become quite soft. Throw away the water and dissolve the gelatine in the acetic acid, applying gentle heat if necessary.

GOOD HEALTH.

Copper in the Human Organism.

Recent experiments by M. Bergeron demonstrate the presence of traces of copper in the human body. The organs examined were the livers and kidneys; and in fourteen instances copper was detected. The experiments were made with 800 to 1,000 grammes of organic materials in each case. Special precautions were taken to prevent the accidental introduction of copper into the solution undergoing analysis. A special chamber was constructed containing no copper; the laboratory tables were of wood; the balance, water-baths, gas-burners, etc., were of iron; and the filter paper, distilled water and reagents were carefully tested, and found to be free from this metal.

The organs were heated in a large porcelain capsule to complete dryness, and afterwards to carbonization. Incineration of the carbonaceous mass was performed in a muffle furnace at a low temperature.

The ash, treated with nitric acid, evaporated to dryness and, redissolved in water, produced a solution which gave reactions for copper—with ammonia, with ferrocyanide of potassium, and with polished steel.

In eleven cases, the organs being taken from individuals varying in age from seventeen to fifty-eight, the maximum amount of copper found was .002 grms.; the minimum amount .0007 grms. In one case, the individual being seventy-eight years of age, the amount of copper was found to be .003 grms. In six other cases, where fetal organs were examined, copper was detected in minute traces.

The copper existing in the organism is without doubt introduced in the use of food.

The use of copper vessels, the daily contact with various objects of copper or brass, coins, keys, etc., introduce in our organs traces of copper, of which the greater part is eliminated; but there remains in a state of combination a minute trace of the metal; which is found in the liver and the kidneys, and this is true whatever the age, sex or mode of life, and averages .002 grammes in weight.

TREATMENT OF WOUNDS.—A wound produced by a sharp cutting instrument will heal without trouble when the edges are nicely brought together and then kept so, and left without putting on any salve, provided the access of air is not shut off and the individual possesses a constitution not undermined by the excessive use of drink or the results of other vices.

If the wound is produced by a rusty nail or a similar cause, so as to be septic, it will soon become very inflamed, and in such a case it is recommended to smother the wound with burning wool or woolen cloth. It is said that twenty minutes in the smoke of wool will take the pain out of the worst wound, and that repeated once or twice it will allay the worst case of inflammation arising from a wound. It is claimed to have saved many lives and relieved much pain, and assuredly it is worth trying.

Typhoid Fever.

If you knock a man down, he may rise up again, but after two or three such knockings, he loses the power of rising. In ordinary fevers the system has a recuperative power, especially when the weight of the malady has been removed by suitable medicine; but when that recuperative power is lost, the system will not rise to health, although medicine has done all that was expected from it, and the patient dies. This inability may exist in all forms of disease. "Typhoid" means "like typhus," and typhus itself means "stupor," a kind of sleep or death. There is a growing tendency in all diseases "to take on the typhoid type," which simply means that the constitutions of the people are growing weaker and weaker, less and less capable of resisting the onsets of disease; hence a less amount of sickness kills now than formerly; and added to this, physicians of every grade have observed that their patients can't bear as large doses of medicine as heretofore; and the tendency is to give less and at longer intervals, and wait and see "what nature will do." The practical use to be made by the reader of these facts is to habituate himself to a greater watchfulness against the causes of all disease, and to a greater care of himself when he is sick; and this care should be observed in three main directions:

1. In recovering from any form of disease, keep abundantly and comfortably warm.
2. Stodiously avoid taking cold.
3. Watch against over-exercise for several days or weeks.
4. Eat very moderately and at regular intervals, of plain, nourishing food.

If these four things are observed, relapses would be rare, and the patient would be saved. The most difficult of the four is to avoid eating too much; there is special danger of yielding to a craving for some particular kind of food. We knew an estimable lady who was happily recovering from an attack of typhoid fever, but she had such a strong desire for a sweet potato that it was allowed her; in less than an hour the symptoms became unfavorable and she died the next day.

The sleepiness or stupor arises from the fact that the brain, and thence the whole nervous system, is oppressed by the disease; is weighed down; can't act; goes to sleep and dies!—*Hall's Journal.*

A MAN DIES OF THE HICCUGHS.—One of the most singular cases of death that ever came within our province to mention, is that of Milton W. Blair, of Louisa county, who died last week in a town in California, of the hiccoughs. Mr. Blair is an old merchant of Louisa county, but has not been engaged in business for a number of years. He has been residing near Morning Sun since retiring from business. Last fall he was attacked with a fit of hiccoughing, which continued for some weeks, with scarcely any intermission. Becoming alarmed at the long continuance of the spell, Mr. Blair came to Burlington to consult with a doctor, who, after treating him awhile, declared he could give him no relief. From this city he proceeded to Chicago, and consulted the best medical authorities there, who did all in their power for him, but could not relieve him. By their advice he went to California, accompanied by his sister, thinking that the change of climate would help him; remaining in that State to the time of his death, hiccoughing almost continually, and having but few intervals of rest. The continued strain and distress wore him to a mere shadow of his former self, and last week his sister telegraphed to friends and relatives in this and Louisa counties that he was dead, and she was bringing his remains on for burial.—*Burlington (Iowa) Hawkeye.*

WALKING EXERCISE, as a means of health, is the most practical and universally available of all other forms; it promotes the activity of the circulation; it enlivens the spirits; exhilarates both body and brain, and, not least, it costs nothing. But to take a lively, active, brisk, cheerful walk, which infuses a new energy into the whole being, there should be a well-fitting shoe, and feet undeformed by corn or bunion, or other distortion; but, standing at any point on Broadway, and taking the first hundred persons over twenty years of age, for examination as to the condition of the feet, we may feel very sure of not finding half a dozen which are natural. It fairly makes one shiver to look at the exposed foot of any adult—ngly protuberances, bony excrescences, turned-in nails, piled-up toes, and skin all mottled and scarred by excessive hindering or ill-fitting shoes, all inclining us to pity human nature, if not to despise it, for unnecessarily submitting to the numerous evils arising from the unnatural conditions referred to.

THE DURATION OF LIFE.—The old saying is on the duration of life appear in a German paper: In ancient Rome, during the period between the years 200 and 300 A. D., the average duration of life among the upper classes was 30 years. In the present century, among the same classes of people, it amounts to 50 years. In the sixteenth century the mean duration of life in Geneva was 21.21 years, between 1814 and 1833 it was 40.68, and at the present time as many people live to 70 years of age as 300 years ago lived to the age of 43.

DOMESTIC ECONOMY.

The Art of Cooking—No. 2.

FRYING.—That part of cooking is not as difficult as it is generally believed, and properly fried objects are good and do not taste greasy. To fry requires care, and nothing fried will taste greasy if it has been dropped in fat properly heated and in enough of it to immerse the object. When an object tastes greasy, it is not because it has been fried in grease, but because there was not enough of it, or because it was not properly heated, for, if heated enough, it closes the pores of the object and carbonizes the exterior, so that it cannot absorb any.

ROASTING.—When an object is placed on the spit according to directions, remember that it cannot be basted too often. The time necessary for roasting a piece of meat, or anything else, depends as much upon the fire as upon the nature of the meat. Meat especially requires to be placed very near the fire at first, and then put back by degrees. There is nearly as much difference between roasted and baked meat as there is between broiled and fried meat. It is generally admitted here that English roast beef is so superior to American roast beef that it cannot be compared to it. It is not in the quality of the meat that the difference lies, but in the process of cooking. Meat cannot be roasted in an oven, be it in an ordinary or in a patented one. That peculiar flavor in roasted meat is produced by the air coming constantly in contact with the heated meat while revolving on the spit. Cold roast meat, when desired to be served warm, is enveloped in a battered paper and placed on the spit just long enough to warm it.

SEASONING.—This is the most difficult part in the science of cooking. To season is not difficult, but to season properly is quite another thing. It is not only necessary to know well how to stew or roast a piece of meat or anything else, but to know how to season it, to be able to judge what quantity and what kind of spices can be used to season such or such a dish, to what extent all the spices used agree together, and what taste and flavor they will give to the object with which they are cooked; for, if not properly used, they may just as likely destroy the taste and flavor of the object as improve it. Some dishes require high and much seasoning, others just the contrary. With a good fire and a good spit it is not necessary to be a thorough cook to roast a piece well, but the cook is indispensable to mix the gravy or sauce with the proper seasonings.

SIMMERING.—Simmering differs from boiling only in the amount of heat allowed under the boiler, kettle, or pan. To simmer is to boil as gently and slowly as possible.

SEWING.—To sew properly it is necessary to have a moderate fire and even as possible. A brisk fire would cause much steam to evaporate, which steam is the flavor of the object stewed.—*The Housekeeper.*

Routine Work.

The recurring duties which the change of seasons brings naturally suggests the fact that the greater part of the life of the average man and woman is spent in doing the same thing right over and over and over again. Every spring the housewife renews her house, in order, in cleanliness, in comfort, reclothes the members of her family, and makes due preparation for the summer. She does essentially at this time the very same thing that she did the last season, that she will do the next. If she is a good housekeeper, each succeeding season makes the task easier because she is more accustomed to it and should know how to take it to better advantage than ever before, but the task is still the same.

The farmer plows the same fields that he plowed last spring, harrows them, plants them, and then goes over them again and again, and again with hoe or cultivator till the harvest, so far as he can make it so, is secure. The merchant takes account of stock just as he did last year, lays in his goods for the summer season, depends and widens the channels of his trade, if possible, but lets the channels remain the same. In like manner the mason, the carpenter, the compositor, the teacher, the editor, the lawyer, the physician, minister, do over the same work from week to week, from month to month, from year to year, with variations so slight that the routine seems essentially the same. Of course all this monotony sometimes gets tiresome and we clamor for a change and fancy that some other mode of industry will be easier and more agreeable than that which circumstance or choice has made ours—that somebody else is better off in this respect than we are. But when we get inside of the life of that somebody else we find that routine work makes up the larger portion of it, and that without the mastery of routine work in the lower fields success in the higher ones had never been attained. The biographies of all who have achieved nobly, shows this so plainly that he who runs may read.—*N. Y. Tribune.*

TO CLARIFY DRIPPING.—Put the dripping into a basin; pour over it boiling water, in which a teaspoonful of salt has been dissolved, and keep stirring the whole to wash away the impurities, let it stand to cool, when the water and dirty sediment will settle at the bottom. Repeat this operation at least twice with fresh water. When cold, remove the dripping from the water and melt it into jars.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—"Sheep Back"
Rocks; Improved Quicksilver Furnace; Improved
Rock Drill, 345. Among the Foundries; Chances
for Finding Mines; Short Lectures on Patents; En-
gineering Items; San Francisco Microscopical Soci-
ety, 352. Gravel Mining; Mint Operations; New
Patent Camp Lunge; Notices of Recent Patents,
353. General News Items; Patents and Inventions,
357.

ILLUSTRATIONS.—View on Roche Montanose
Creek, Colorado; Outler's Improved Quicksilver Fur-
nace, 345. Economy of the Vegetable Kingdom,
350. Ladies' Camping Lounge; New Patent Camp
Lounge, 353.

MECHANICAL PROGRESS.—Progress in Iron
Work; Expansion and Contraction of Boilers; The
Extension of the Iron Trade in Japan; A Gun Manu-
factured in an hour; American Ordnance—A Novelty
in Gun Manufacture; Recipe for a Cement for Mend-
ing Steam Boilers; Needle Making, 347.

SCIENTIFIC PROGRESS.—The New Method
of Electric Illumination; A New Earthquake Indi-
cator; Safety-Lamps not Always Safe—and Why? New
Method of Preserving Meat; The Planet Uranus;
Failure of Copper Sulphate; Music from Gas Jets;
New Electro Process; Interesting Discovery, 347.

MINING SUMMARY.—From the various counties
in California, Oregon, Nevada, Arizona, Colorado,
Idaho and Montana, 348-9.

POPULAR LECTURES.—Economy of the Vege-
table Kingdom, 350.

USEFUL INFORMATION.—The Fahrenheit
Thermometer; Foreign Talent as an Aid to Progress;
How to Make Oil Lamps Safe; The Tender Paper
Opaque and Again Transparent; Green Bronze on
Iron; Liquid Parchment; Making Brittle Gold Strong;
Cement to Unite Brass and Wood, 351.

GOOD HEALTH.—Copper in the Human Organ-
ism; Treatment of Wounds; Typhoid Fever; A Man
Dies of the Hiccoughs; The Duration of Life, 351.

DOMESTIC ECONOMY.—The Art of Cooking—
No. 2; Routine Work; To Clarify Drippings, 351.

MINING STOCK MARKET.—Sales at the San
Francisco Stock Board; Notices of Assessments,
Meetings and Dividends; Review of the Stock Mar-
ket for the Week, 356.

MISCELLANEOUS.—The Stock-Jobbing Juggler;
nant; Elina Sulphur Mine; The New California Mill;
Agricultural and Mining Land; Decisions in Mining
Land Cases; The Richmond Refinery; A Quicksilver
Bonanza, 346. Wood and Iron in Building; Antique
and Walnut Furniture Finished in Oil or Wax; Re-
moving Paint from Windows; The Elder; English
Iron in the United States, 350.

Among the Foundries.

Risdon & Tower, managers of the Pacific
Boiler, Sheet Iron and Water Pipe Works, are
now engaged in making the boilers for the new
"C & C" shaft on the Consolidated Virginia
and California mines on the Comstock. They
are also making two sets of boilers to go to Pan-
amint mining district. They are making boiler-
era to go to Peru, and have a large amount of
other work contracted for. Fifty men are em-
ployed at these works, all kinds of boiler and
sheet iron work being done and high and low
pressure boilers built and repaired. The of-
fice and works are 118 and 120 Fremont street,
between Mission and Howard. Mr. J. N. Ris-
don was formerly of Office & Risdon and Risdon
Iron Works, and Mr. Charles Tower was for-
merly foreman in the boiler works of the same
institutions.

Large amounts of mining machinery are at
present being made by our local foundry and
machine shops. This has perhaps been the
busiest season in this direction our foundrymen
have ever experienced. The machinery being
made is mostly of a heavy and expensive char-
acter and of the most improved patterns.
Scarcely any of the foundries are without or-
ders for mining machinery of some kind.

At the Pacific Iron Works, on First street,
the immense hoisting works for the joint shaft
of the Consolidated Virginia and California
mines on the Comstock, are rapidly approach-
ing completion. We described the machinery
in detail a few weeks since, so that our readers
probably remember its large proportions. It
will be the heaviest machinery on the Com-
stock.

At the Dayton mine laying of the founda-
tions, and the erection of the new and power-
ful hoisting and pumping machinery is being
pushed to completion with all the energy pos-
sible.

Chances for Finding Mines.

The limits of the areas on the Pacific slope
which are unexplored by the prospector, are of
course being gradually reduced, but there still
remains much country which, for all practical
purposes, is unknown to the miner. It is not
enough for his purpose that nearly all parts of
the country are, even when not settled up, oc-
casional visited by hunters, stock men, etc.,
or run over hastily by people not seeking pre-
cious metals. Every day fresh discoveries are
being made in places which have had a small
population in the vicinity for years, and we have
no reason to assume that a tract contains no
gold, silver, lead, coal or quicksilver, because
up to the present time it has not attracted the
attention of the miner. The prospector has
not to travel far to find new country, and in
the neighborhood of older mining districts
there are many tracts yet undeveloped. More-
over, there are many claims which were aban-
doned years ago, before perfect appliances for
saving the precious metals were thought of,
and when labor and food was high.

It is, moreover, by no means certain that be-
cause other prospectors have passed over
ground that there is nothing to be found.
Many of us remember instances where ground
was supposed to have been thoroughly pro-
spected, and after perhaps a hundred different
men had gone over it, another man would
come along and strike it rich. The writer
remembers having camped in one locality a
week with three other prospectors, and thor-
oughly worked over a small section, finding
nothing. Two weeks after two men camped at
the same spring, and found a vein cropping
out, which, after working about three years,
they sold for \$130,000. This vein was not 200
yards from the spring where the camps were
located, and the first party had passed over the
croppings, which were small, many times with-
out seeing them. This is by no means an
isolated case.

Many old miners, however, prefer to work
and re-work well known gulches and flats rather
than spend their time in making trials in new
ground. It is often stated that in new camps,
the miners, curiously enough, almost always
accidentally open the richest claims first; but
those who make this statement do not always
take care to examine the facts. At first new
discoveries—the finding of any rich pocket,
excited the public mind, and even without ex-
aggeration, the facts made known in the early
days of our gold mining were startling; but
more extraordinary results are obtained now,
week after week, than many which occurred in
early days.

When we read a paragraph in a newspaper
informing the public that the last clean-up of
such a claim was \$60,000, or such a mine is
raising 200 tons of ore per day, worth \$150 per
ton, there is neither surprise nor excitement.
The public has become accustomed to regard
these as ordinary occurrences, and fails to con-
trast them with what was presented to their
observation ten or fifteen years ago. In Cali-
fornia, this is more particularly noticeable in
quartz mining.

In fact, the prosperity of California mining,
paradoxically, stands in the way of its advance-
ment. If our miners were not well off, if they
had not good machinery and appliances to aid
them, if they were obliged only to select the
richest rock, and pound it up in a mortar, as is
often done in new camps, the results of their
labor when made known would attract hun-
dreds to the mines. But merged in averages
and given in bulk, they fail to convey intelli-
gence which excites the mind. In many cases,
if miners had to select the rock, as in early
days they used only the richest dirt, results
now often obtained would seem so extraor-
dinary as almost to exceed belief.

Take California, for example, with regard to
new mines. Ten years ago it was thought
that at this time there would not be a thousand
miners in the State, but there are more than
ever before. All this time with quicksilver as
valuable as it was, there were only two or three
mines of this character being worked. Last
year, when the price of the article was very
high and a new mine or two was found, pros-
pectors started in all directions, and the result
was that many people found the precious metal
almost under their noses, on their ranches, near
their towns and in all directions. It has been
found in all the coast counties from Mendocino
to San Diego and away back in the interior.

The measure of the success of the mines
must not be gauged by our exports alone, nor
must it be gauged altogether by the published
statements of hullion product. Immense sums
have been expended in all the mining States
and Territories in the construction of roads,
ditches, mills, machinery, etc. In many places
large towns, with fine buildings, etc., show
that no small share of the wealth the mines
have yielded has been profitably used in turn-
ing the wilderness into a habitable abode. In
many places where a few years ago man's step
was unknown, we hear now the roar of hun-
dreds of stampheads, the rush of water, and
see the hills stripped of their trees, the streams
elevated from their natural beds, fine houses,
wide streets, tall chimneys, churches, theaters,
etc. If in some places there has been a profuse
outlay, it has not been that of the spendthrift,
but rather that of the wise, enlightened and
perhaps too liberal population, who have faith
in their prospects, and show it more in deeds
than words.

Short Lectures on Patents.

Nb. 6—By JND. L. BOON, of Dewey & Co's MINING AND
SCIENTIFIC PRESS Patent Agency.

Re-Issues.

If the patent covers more than the inventor
is entitled to claim, or if it does not cover all
that he might claim, it can be re-issued and
the trouble remedied. There is no limit to the
number of times that a patent can be re-issued.
In applying for a re-issue a new or amended
specification, and new or amended claims are
presented to the Patent Office for action. If
the application is granted the old patent must
be delivered up and a new patent or re-issue is
issued to the inventor, and the new patent will
stand in lieu of the one originally issued. A
re-issue does not extend the life of the patent
but it will expire on the day that the original
patent would have expired had it not been re-
issued. A re-issue is not retroactive in its
operation. It cannot reach the infringer of the
original patent if the original patent could not
do so, and even then the infringement must be
continued after the date of the re-issue. The
old patent stands as a repealed act while
the re-issued patent goes into force on the day
of its issue.

Nothing can be claimed in a re-issue which
does not appear in the application on which
the original patent was issued. The specifica-
tions can be re-written entire, new claims may
be substituted instead of the old, but no new
matter, nothing discovered or invented since
the issue of the old patent can be embodied in
it. An application for a re-issue is examined
the same as if it were an original application,
and the Patent Office can even reject a claim
which is contained in the original patent if it
is embodied in the re-issue and is found on the
re-examination to be wanting in novelty. The
old patent must be delivered back to the Patent
Office if the re-issue application is granted, but
if it is rejected the patentee can withdraw his
old patent and hold it the same as if he had
not applied for a re-issue, and this is the case
even if a portion of the claims contained in the
old patent are rejected, but such a withdrawn
patent is liable to be defeated in a suit at law.

If a patentee has assigned an undivided in-
terest in his patent he cannot re-issue it with-
out first obtaining the consent of the assignee.
If two or more separate inventions are covered
by one original patent, the patentee can in a
re-issue make each invention the subject of a
separate application and receive a separate
patent for each.

To properly prepare a re-issue case requires
the greatest skill of the patent solicitor. It
involves not only the necessary legal knowl-
edge, but a thorough mechanical knowledge
of the principles involved in the invention.
He must develop in clear and unmistakable
terms the little mechanical points which unite
together to form the main idea, and he must
grasp the main and connected features, so as to
make legal and allowable claims on legitimate
and necessary combinations. It is the tearing
down of a poor or defective structure, in order
to build another and a perfect one in its stead
and with the same materials. Knowing the
defects of the original patent, and having had
the experience of actual practice and tests ob-
tained in his endeavor to introduce the inven-
tion to the public, it is expected that the inven-
tor will see that his patent covers the invention,
fully and completely, so as to hedge out possi-
ble infringers.

Usually the defects of a patent, if it has any,
are revealed soon after the patentee introduces
his invention to the public. Our American
inventors do not often permit the patentee to
escape long if he makes a successful invention
without giving him cause to look to the scope
and validity of his patent. His only defence
if any flaw exists is in a re-issue. It is seldom
that the specification and claims of a patent
cannot be proved after the inventor has had
the experience of a year or two before the
public, and it is generally the case that the
Patent Office will allow broader and stronger
claims on a re-issue application than on an
original application. It is usually those who
are successful in introducing their inventions
that apply for reissues. The patents for in-
ventions which cannot be made pecuniarily
profitable are seldom interfered with by in-
ventors, and they do not therefore need to be
re-issued. It is the successful patents that need
to be strong to ward off infringers. It is there-
fore of the greatest importance that these cases
be prepared carefully and by some person who
is skillful, both in law and in a knowledge of
mechanics.

Although the reissue is usually resorted to
for the purpose of enlarging the scope of the
patent, it is also used to lessen its scope when
it contains more than the inventor is entitled to.

It is well that the law provides a means for
remedying the defects in a patent. The coun-
try is over-run with a class of patent agents,
who know but little about the requirements of
a patent, and care less. Their sole object is to
secure patents for their clients, no matter how
much or how little the patents cover, so long
as they receive their pay for getting them. If
the patentee does not succeed in introducing
his invention and making money out of it, he
may never know how poor a patent he holds,
but if he is successful in his attempts to in-
troduce it he soon discovers that in order to
protect himself he must reissue his patent, and
claim what he should or might have claimed in
the first instance.

[To be continued.]

Engineering Items.

Work is still being carried on at the Oakland
harbor improvements. Mr. Gnarin is now
superintending the operations. The first con-
tractor, being unable to fulfill his contract, was
removed, and the second lowest bidder is now
on the work.

PRELIMINARY operations are now being car-
ried on in San Diego for the improvement of
that harbor, by turning the San Diego river
into False Bay. Gen. Alexander, Col. Stewart
and Lieut. Weedon of the U. S. Board of Engi-
neers are now in San Diego making the neces-
sary surveys.

The new revenue steamer for the Pacific
coast is to be built by the Oregon Iron Works,
of Portland, Oregon, their bid being the low-
est—\$92,000. The vessel is to be one of the
staunchest in the service, and will be 145 ft
long, 23 ft breadth of beam and 11 ft depth of
hold. Her draft of water will be 10 ft 10 in,
and she will be of 227 tons custom-house
measurement. She is to be a propeller with a
vertical inverted engine, 34 in. diameter of cyl-
inder by 34 in. stroke, and provided with a an-
tifa condenser.

The following information may be useful to
our steamship owners. It is an extract from a
Glasgow journal of a recent date: "An inter-
esting paper was read before the graduates of
the Glasgow Engineers' and Shipbuilders' In-
stitution, on the 13th ult., on 'Corrosion of
Marine Boilers,' illustrated by sketches and
specimens of boiler plates, angle iron and stays,
exhibiting the riddling effect of the agent to
which the metallic fragments had been sub-
jected. The result was attributed to the pres-
ence inside the boiler of a powerful, volatile,
fatty acid, which speedily dissolved the surface
of the iron wherever it was unprotected by
the water. This acid is the issue of the de-
composition of tallow, which is frequently in-
troduced to excess, for the purpose of prevent-
ing the annoying occurrence known in engi-
neers as 'priming.' In order to neutralize the
effect of the acid, the lecturer recommended
that pounded chalk should be largely used in
boilers, as this substance, by forming a basis,
would render the acid inoperative."

San Francisco Microscopical Society.

This hard working little society held its regu-
lar semi-monthly session last week. The
Committee on Annual Reception made a report
of progress, stating that Mercantile Library hall
had been engaged for Thursday evening, May
27th. Nearly all the members present handed
the committee a list of objects which they would
exhibit on that occasion; and the favored ones
who receive tickets from the members to attend
the reception will find an exhibition most grati-
fying and instructive. We acknowledge the
receipt of an invitation.

Mr. Hyde exhibited a sample of some wooden
ships which he had made from well-seasoned
Spanish mahogany and perforated with one
or more different sized apertures, which he
utilized as cells for dry mounting. The sides
were noticeable for lightness and durability,
but he stated that they were rather more ex-
pensive than glass ships.

Mr. Kinne exhibited a turn-table of his own
invention, which he stated could be attached
to any now in use, and by means of clamps,
levers and light spiral springs, automatically
fixed the slide in a central position for mount-
ing objects, cell-making or finishing. The ap-
pliance was made by Will & Finck, of this city,
under the direction of the inventor, and its
finish and usefulness were both noted and re-
ceived the approbation of all present.

As several members of the society who had
been interested and instructed by the papers
and remarks of Dr. Harkness on the vegetable
cell, were desirous of hearing and seeing some-
thing of analogous animal structure, the Dr.
had prepared a series of objects for exhibition,
which he introduced by a few remarks as to the
general characteristics of the animal in cell,
and which he fully described and alluded to as
the basis of life, all the tissues being eliminated
therefrom. Proceeding to the illustration of
the matter, he exhibited a number of objects,
which had been prepared by himself and
mounted for the evening's study. The meet-
ings of this society are always well attended,
and great interest is manifested in the proceed-
ings, both by members and visitors.

Progress at the Sutro Tunnel.

The following is the report of progress in the
Sutro tunnel, for week ending May 22, 1875:

Number of feet in tunnel, May 15.....	9,408
Number of feet driven during week.....	57

Distance in, May 22.....	9,475
--------------------------	-------

Details of work performed, are as follows,
heading being 8x10 feet:

Holes drilled.....	460
Holes blasted.....	460
Holes re-blasted.....	76
Aggregate depth.....	2,530 feet
Average depth.....	5 to 10 feet
Powder consumed.....	1,315 lbs
Explosives consumed.....	640
Car loads.....	379

Six drill, instead of four, will soon be set at
work, probably by the end of this week.

[Signed] A. SUTRO, Gen. Supt.

Gravel Mining.

Generally throughout the State a short water supply for hydraulic mining is expected, and most of the gravel mining enterprises are being pushed ahead with vigor at present, to make the most of the present abundant water supply. The result of most of the operations coming under our notice is quite favorable and the aggregate yield will doubtless be larger than usual. In many localities new enterprises are being started up and larger areas of ground will next year come under the pipe. In Calaveras county all the hydraulics are running full banded and the tunnel claims are being worked to the extent of their capacity. The Calaveras *Chronicle* states that a number of abandoned claims have been re-located, and there is no question but there are extensive gravel fields within the reach of the water company's ditch, yet comparatively unprospected, that can and will be profitably worked. For several years past, especially since the more modern appliances for hydraulic mining came into use, the gravel mining interest has been constantly increasing in importance, until it has reached a place second to none other in the county. Further development in that direction is stimulated by the success so uniformly met with and the *Chronicle* thinks they can safely calculate on a steady enlargement of the field of operations.

In Plumas county the recent strike of blue gravel under the lava cap at Neelon Point promises to be one of the most important discoveries made in the county for years. The owners of the ground, Messrs. Pierson, Winters & Jolly, have been pushing their tunnel along, and although they are not on bedrock, are getting splendid pay. The Plumas *National* is credibly informed that the gravel in the top of their tunnel prospects at the rate of twenty-five cents to the pan. The layer of gravel is from fifteen to twenty feet deep from the bedrock to the lava cap, and as it seems to run wherever the lava is found, it gives promise of being very extensive. Considerable excitement has been raised in mining circles, and the ground, it is said, is already claimed for over two miles. There is talk of making up a company to start in another tunnel. Should this prove to be the continuation of the blue lead it will bring back the old-time flush times to Nelson, and make it one of the liveliest mining camps in Plumas county.

Another strike in the ancient river channel was recently made at the Rough and Ready claim, on Table mountain, near Peoria Flat, owned by the Tuolumne hydraulic mining company. The Tuolumne *Independent* states that they have four feet of blue gravel in the face of the tunnel, with an overlay of two feet of secondary wash, red gravel, which latter prospects well. The former, the regular blue gravel, prospects all through from one to two bits to the pan. This claim was formerly worked by hydraulic, and the red gravel was supposed to be the cream of the mine, but after about two years' trial the Superintendent concluded there must be another channel in the mountain, which he went after with a determination to find. He commenced tunneling, starting from the old tunnel, which was 1200 feet in. He, however, started from a point 800 feet from the mouth, and commenced running levels up the mountain, and struck the old river bed as before stated. Wherever this has been found in Table mountain heretofore, the old channel has proved immensely rich. Taking the lay of the ground, they have probably the best thing yet struck in the county. The gravel is expected to average ten to twelve dollars to the car load, and they are working night and day shifts.

The channel spoken of here, as most of our readers probably know, runs through the whole length of Tuolumne county, in Table mountain, and spots equally rich have been found in most cases where the old bed has been reached. All up and down the mountain are tunnels given up years ago, many of which are probably within a few feet of the old channel; but the coin and patience of old prospectors gave out before they reached the reward which will be repaid hereafter by those who have the faith to invest.

At Michigan bluff, Placer county, old miners who reside there estimate that there are ten thousand acres of good paying mining ground in that divide now lying in its primitive state for want of capital to open it up. Hydraulic mining is extensively carried on at Michigan bluff, but the Placer *Herald* thinks that tunnel mining is bound to take the lead there. To open and work a mine on this principle, as on the hydraulic principle, requires extensive capital. Hence much of the ground in that section—perhaps the best—has never yet been touched. There are many drift claims at or near the bluff now, but they are being worked, but not one tenth what might be. Several are now being worked with profit and others are being fitted up. The principal hydraulic mines now in operation at Michigan bluff are the Big Gun, Light Foot, and Sage Hill. These and other smaller mines in that vicinity have had quite a successful run, though their season is destined to be short. The water is already beginning to fail, and in a few days more the ditch company will shut off the supply entirely in order to repair and improve the ditch.

The Gene-e Valley mine, in Plumas county, recently incorporated, is a little mine which has paid steadily in a modest way ever since it was discovered and opened in 1854. No assessments have been levied on it. This mine was first worked as a hydraulic mine, yielding an average of six or eight dollars per day to the

man. The bed rock exposed by the water showed a perfect network of small veins of decomposed quartz, some of them fabulously rich. As high as \$70 has been taken from a single pan of this decomposed rock. When the surface ground was exhausted a small mill was erected, and its stamps have been busy ever since, and always with good results, and the *National* is informed that the prospects of the mine are to-day as good as they ever were.

A circumstance of this kind ought to encourage prospectors in other directions. In this connection we notice the Grass Valley *Union* recommends prospectors to try the head of Squirrel creek, in Nevada county, for quartz. A week or so since a lot of beautiful gold nuggets, taken out of James Gassaway's claims, on Osceola ravine, were shown in a Grass Valley bank. The nuggets were valued in all at \$450, and the largest was worth \$115. They came from near the head of the ravine. Osceola ravine empties into Squirrel creek, and the creek has always been noted for having heavy lumps of gold in its bed. It is quite probable that a large quartz ledge exists somewhere near the head of Squirrel creek, and the *Union* advises prospectors to hunt it up.

Mint Operations.

Professor R. E. Rogers, of the University of Pennsylvania, who arrived in this city last

LADIES' CAMPING LOUNGE.

week, commenced immediately to prepare the refinery for the mint. This refinery will have a capacity of 1,500,000 ounces per week. The present refinery, at the corner of Brannan and Seventh streets, is able to refine \$1,000,000 monthly. The refinery at Carson has a capacity of \$300,000 monthly, and that of New York a capacity of \$1,000,000 per month. No refining is done at the Philadelphia mint, and little elsewhere in the country. The aggregate capacity of all the refineries of the United States is at present far behind the production of the precious metals, and likely for some time to remain so.

NEW PATENT CAMP LOUNGE.

The United States mint, in this city, is the finest establishment of the kind in the United States, being able to coin \$2,000,000 per month in silver and \$3,000,000 in gold. The coinage for this month will probably amount to about \$3,500,000, making a total for the last eleven months of \$30,000,000. Double eagles and twenty-five cent pieces are now being coined, and the coinage of the twenty cent pieces will soon be commenced. This new coin is described as follows: "On the obverse side a female figure sits, holding in her hand a pole bearing the liberty cap, the whole representing the usual figure of the Goddess of Liberty. Underneath the figure are thirteen stars, representing the thirteen original States of the Union. On the reverse side is the figure of an eagle displayed, surrounded with the inscription 'United States of America,' and the denomination of the coin. A rim inside the edge and the edge itself will be ribbed, as are our other coins."

The new refining machinery is being put in place as rapidly as possible, under the direction of Professor Rogers, who has been sent out by the government for that purpose. It is said that the Professor has some new methods, which he will put to practical test, that will greatly facilitate the process of refining.

The new "C & C shaft" on the California and Consolidated Virginia mines is making rapid headway, the work being driven with all the energy possible. The foundations for the new machinery are fast approaching completion, and preparations for the erection of the different portions are being forwarded with all the speed possible. The grading for the new mill is about completed.

New Patent Camp Lounge.

To people who are accustomed to go on camping trips every summer, and to hunters, prospectors and others who frequently sleep out of doors, the patent camp lounge shown in our illustration on this page is of interest. As may be seen from the engraving, it makes a light compact couch, easily carried and capable of being quickly arranged for use. The invention is simply a piece of canvas, which, when stretched on a frame, forms a bed or lounge. There are two side sticks, three feet nine inches long, and two girths, one at the head and one at the foot, forming the transverse portions of the frame. The girth forming the head is straight, and into its extremities the shanks of the double ferrules are screwed with right and left hand threads. The inner pair of ferrules receive the ends of the side sticks. The shanks of the ferrules of the lower girth are arched so as to raise the hip of the person reclining a short distance above the ground. The width of the frame can be extended at pleasure. In putting the couch together the side sticks are inserted through the side hems and the head girth through an additional head piece. The foot girth rests on the ground. The girths are

then turned to proper width and the canvas stretched tightly. In order to support the lounge at a suitable incline, two sticks are inserted in the outer ferrules of the double ferrules on the head girth, said ferrules being formed at right angles to those to which the side sticks are inserted. A loose piece of canvas is provided, secured to the main portion, and which rests upon the ground beneath the lower portion of the body and feet of the occupants. The small compass and convenient shape into which the device can be folded is shown in the small cut. It comprises the head and front girths and canvas.

It is not absolutely necessary to carry any of

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

IMPROVEMENTS IN WINDMILLS.—Albert H. Southwick, San Francisco, Cal. This invention relates to improvements on the "Dexter" windmill, which was patented by the same inventor. The present improvements relate to the construction of and arrangements for operating the shutters by which the wind force is admitted, regulated and cut off entirely, when desired, from the wind-wheel. In the "Dexter" windmill a horizontal wind-wheel is mounted inside of a suitable frame or awning and is surrounded by a series of overlapping shutters, mounted on suitable bearings and connected together so that they can be simultaneously opened and closed, so as to regulate the speed of the wheel by ganging the quantity of wind admitted to it. In constructing these shutters the inventor secures, longitudinally along the middle line and on each side of each shutter, a rib or baton, which will prevent it from warping; and to each end of the shutter is secured a metal shoe which also aids in keeping it from getting out of order, and preserves its easy movement in its bearings. The bearings of the shutters being made of metal, the shutters cannot bend or become stiff. The inner or overlapped edge of each shutter is made angular, so that when the shutters are closed the angular edge will fit closely against the inner outside edge of the next shutter and make a tight joint. The angular edge will also project inside of the plane of the shutter and thus form a wing which will receive the force of the wind as it passes between the shutters. Therefore, when the wind increases in force its action upon this wing will tend to close the shutters in proportion to the pressure of the wind. The rods which connect the shutters are so secured that the length of the rod can be adjusted after it has been secured in place. To provide for the simultaneous adjustment of the shutters the upper end of two opposite shutters is extended through the ceiling of the frame or housing, so as to provide a projecting end above the ceiling, to which a crank arm is secured. A lever extends across above the wind-wheel and is pivoted at its middle so as to provide two arms. One end or arm of the lever is connected with each of the crank arms by a rod, so that by moving the lever about its center or groove the shutters are simultaneously opened or closed. A cord is attached to each end of the lever and extends down outside of the frame to within easy reach of a person standing on the platform of the mill. By drawing upon these ends the lever is shifted and the shutters operated. The shutters can be turned with precision and held at any desired position. This invention greatly improves the "Dexter" mill by obviating faults which it has heretofore possessed.

BIT STOCK.—E. R. Charles, Petaluma, Sonoma county, Cal. This is an improved tool holder and bit stock, in which is a novel arrangement for securing tools or bits in handles, so that they can be readily removed, and which will at the same time hold the tool or bit securely when fastened to the handle. The hole in the end of the stock in which the base end of the bit is inserted is made round, and along one side of the hole is made a groove. The inserted end of the tool is made round to fit the hole and has a rib on one side which fits into the groove referred to. A short distance from the end of the bit stock a groove is made entirely around it, and in this groove is fitted a ring with a milled edge, which can be turned by the fingers. In the bottom of the groove in which the ring fits is a slot on one side of the groove, and on the inside of the ring is a projection so that when the ring is turned in one direction the projection will be moved across the groove. The rib in the base of the handle has a recess out in it at the proper point to allow the projection on the ring to enter it when the tool has been inserted in the stock and the ring has been turned so as to bring the projection across the groove, thus fixing the tool firmly in the handle or stock. This arrangement is quite simple and extremely strong, while it is easily operated to place and remove tools.

BRAKE BLOCKS.—Wm. Hendricks, Milton, Stanislaus county, Cal. This invention relates to certain improvements in brake bars and the securing of the independent brake blocks to these bars so that the block is firmly held in its place. The brake bar is not weakened by cutting it away inside of the line of wheel and the screw which operates to secure the block is protected from injury from the outside. The block can also be adjusted to accommodate the increasing "dish" of the wheel by use.

THE BLACK HILLS.—A company of cavalry has passed through Dubuque, Iowa, en route to Yankton, Dakota. They were well equipped, and intend to keep a vigilant eye on the movements toward the Black Hills. General Canby says his expedition to the Black Hills will leave Fort Lincoln June 1st, and if miners are going into the Hills in large numbers, as Western papers report, it will probably take the whole summer to drive them out.

SAFE INVESTMENT.

The Pacific Coast Twelve Per Cent.
Consols.NEW METHOD WITH ASSURED AD-
VANTAGES.

A rapidly growing interest is being taken in the Pacific Coast Twelve Per Cent Consols, in consequence of the many advantages offered in regard to investment, interest and dividends. So much uncertainty exists in connection with nearly all mining and other speculative companies, there is something very assuring in an incorporation which not only guarantees twelve per cent. per year to all stockholders, but provides for the honest payment of dividends. The Twelve Per Cent. Consols were incorporated on the 12th of February last, for the purpose of transacting a general business in buying and selling mining properties, city real estate, and agricultural and other lands, in the States and Territories of the Pacific Coast. Determined to do only a strictly legitimate business, the Directors rejected the old method in vogue by mining companies generally, and adopted a new one which secures to all parties who become shareholders, equal advantages in the business transacted. By the provisions of the by laws,

A Sinking Fund

Is to be made of one-half the proceeds of the total capital stock, which shall be held on the joint account of the original co-owners. The stock will be classified as follows: Sinking Fund, mining property, city real estate and agricultural lands. Before any stock is issued in any class, the property will be appraised by the owners, and the stated value entered upon the books of the Company. Shares for not more than fifty per cent. of the valuation will be issued in any of the classes, and the amount of shares offered for sale in any one class, exclusive of the sales of stock in the Sinking Fund, will not be allowed to exceed 50,000, if sold at less than the par value of a dollar per share.

Guarantees of Safety.

In regard to the Sinking Fund, which will constitute fifty per cent. of the par value of the stock, all moneys received as the proceeds of sales of stock on account of the fund will be deposited with some solvent banking institution, which pays interest on deposits invested in interest bearing stocks, bonds and other securities, which can be realized on in thirty days, and in no case will it be lawful for the directors or trustees to invest any moneys of the Sinking Fund in the purchase of stocks, bonds or other securities of any incorporation whatever, which shall have failed to pay interest or dividends for a period of six months preceding any proposed investment pertaining to the Sinking Fund of the Company.

Payment of Interest.

The by-laws further make positive provision for the payment of interest monthly on all stock issued in each class at the rate of twelve per cent. per annum, payable on the 5th day of each month. Another important concession is that any shareholder has the option to take stock in payment for interest at par value in any class that may be preferred. No assessment will be levied until the total stock of the Sinking Fund shall have been sold and paid out as provided by the by-laws. Indeed, so secure is the plan of the Company that in case the whole capital stock of the Company should be sold immediately and the Sinking Fund invested as provided, the proceeds would be sufficient to pay the interest for eight years and a half on the total capital stock. Perhaps no other company in the world has ever been able to present so brilliant a certainty.

Dividends.

Stockholders will not only be sure of their twelve per cent. per annum, but will share in all the surplus profits. The dividends will be paid from the profits and sales of property, and only on shares of consols that have been issued for property valued and entered on the books of the Company. As there can be very little question that the transactions of the Company will be very extensive, and that the profits will rapidly reach something handsome, the dividend prospect should serve as a strong inducement to stock purchasers, for perhaps in no other direction can they be positive of receiving one per cent. a month for money invested, and almost a certainty of large yearly dividends in addition.

A further provision can be made at any time by the Company by setting aside the percentage agreed upon of the sales of the properties of the Company. The main object of the directors is to incorporate a more legitimate and assured method of transacting business in mining and property than has hitherto obtained on this coast. They are therefore resolved to touch nothing but bona fide investments, and to make it a rule to have nothing to do with speculative values. Every possible care will be taken to protect the interests of shareholders; and in order that they may be constantly posted in the transactions of the Company, a monthly statement of affairs will be prepared by the officers, and the books will be at all times open for inspection. Shares for the first series issued for mining property in Washoe, Storey and Lyon counties, and on the Comstock lode in Nevada, and for account of Sinking Fund, will be ready for delivery to subscribers and purchasers to-morrow, at Greenbaum & Co's, 306 Montgomery street. The net selling rate will be one-twenty, and the buying rate one-nineteen. The principal office of the Company is at 306 Montgomery street. T. Phelps is the President, and W. S. Reynolds the Secretary. my22sohwbp

Epilepsy or Fits.

A sure cure for this distressing complaint is now made known in a treatise (of 48 octavo pages) on Foreign and Native Herbal Preparations, published by Dr. O. Phelps Brown. The prescription was discovered by him in such a providential manner that he cannot conscientiously refuse to make it known, as it has cured everybody who has used it for fits, never having failed in a single case. The ingredients may be obtained from any druggist. A copy sent free to all applicants by mail. Address, Dr. O. PHELPS BROWN, 21 Grand street, Jersey City, N. J.

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR APPLICATION—requiring no thinner or dryer, and will not spoil by standing any length of time.

It is Cheaper, more durable, more Elastic, and produces a more Beautiful Finish than the best of any other Paint.

It will not Fade, Chalk, Crack, or Peel off, and will last twice as long as any other Paint.

In ordering White, state whether for Outside or Inside use, as we manufacture an Inside White (Flat) for inside use, which will not turn yellow, and produces a finish superior to any other White known.

Put up in 4, 5, 12 and 5-gallon packages, and in Barrels. Sold by the Gallon.

For further information send for Sample Card and Price List, or apply to the office.

DIAMOND
REMEDIES.

DIAMOND INVIGORATOR.

DIAMOND NERVE PILLS.

CATARRH AND COLDS—Dr. Evory's Diamond Catarrh Remedy never fails; perfect cure; try it; fifty cents per bottle. Depot, 608 Market street, San Francisco, Cal., opposite Palace Hotel. Sold by all druggists.

This is a Sure Cure for Screw Worm, Scab and Foot Rot in Sheep. It also kills Ticks, Lice, and all Parasites that infest Sheep.

Prevents scratching and greatly improves the quality of the wool. One gallon of the Dip properly diluted with water will be sufficient to dip one hundred sheep, so that the cost of dipping is a mere trifle, and sheep owners will find that they are amply repaid by the improved health of their flock.

The Dip is guaranteed to cure when used according to directions, and to be vastly superior to Corrosive Sublimate, Sulphur, Tobacco, and other remedies which have heretofore been used by farmers.

Circulars sent, post paid, upon application, giving full directions for its use, also certificates of prominent sheep growers who have used large quantities of the Dip, and pronounce it the most effective and reliable known Cure and Preventive of Scab and other kindred diseases in Sheep. m18-bp

Ayer's Cherry Pectoral,

For Diseases of the Throat and Lungs, such as Coughs, Colds, Whooping Cough, Bronchitis, Asthma and Consumption.

The few compositions, which have won the confidence of mankind and become household words, among not only one, but many nations, must have extraordinary virtues. Perhaps no one ever secured so wide a reputation, or maintained it so long, as AYER'S CHERRY PECTORAL. It has been known to the public about forty years, by a long-continued series of marvellous cures, that have won for it a confidence in its virtues, never equalled by any other medicine. It still makes the most effectual cures of Coughs, Colds, Consumption, that can be made by medical skill. Indeed the CHERRY PECTORAL has really robbed these dangerous diseases of their terrors, to a great extent, and given a feeling of immunity from their fatal effects, that is well founded, if the remedy be taken in season. Every family should have it in their closet for the remedy and prompt relief of its members. Sickness, suffering and even life is saved by this timely protection. The prudent should not neglect it, and the wise will not. Keep it by you for the protection it affords, by its timely use in sudden attacks.

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at a price which will bring it within the reach of every household.

It is unequalled for cleaning Woolen Fabrics, Cutlery, Carpets or Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing. It renders water soft, and imparts a delightful sense of coolness after washing.

DIRECTIONS.—For Laundry, use two to four table-spoonfuls to a washful of water. For bathing, use one table-spoonful in the bathtub. For removing grease spots, apply with a brush, undiluted, and wash with water afterward. For stimulating the growth of plants, use a few drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.

Also, SULPHATE OF AMMONIA for chemical purposes, fertilizing, and the preparation of artificial manure. AMMONIACAL PREPARATION for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing, and PURIFIED LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes. Manufactured by the

JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco

The Mining Stock Market

Mining stocks still continue in a depressed condition, although some signs of improvement in prices have been manifested this week. As will be seen by our stock quotations, Ophir still comparatively low in price, although whether it is not even now higher than the mine warrants is a question. The stock has fluctuated between \$40 and \$50 during the week, and no one seems to know what way it is going. Mexican follows it steadily up and down, as in fact do most of the Comstock mines. Even the Houanzas mines feel to some extent the depression caused by Ophir's downfall. All along the line of the Comstock, however, according to the local papers, more or less better development work is being done than ever before, and more capital being effectually employed.

The new Pacific Stock Exchange now has seventy-nine members, including some of the heaviest capitalists and dealers on California street. These men are mostly desirous to do business with the old Board, preparatory to transferring it to the Exchange, and the effect is apparent. The withdrawal of a few such men as Baldwin, Kellogg, and a score of others we might name, is a serious blow to the usefulness of the old Board, and their places cannot be filled.

A handsome premium is now offered for seats, \$10,000 being bid, with no takers. The Exchange has secured the Museum property for which \$325,000 will be paid as soon as the necessary preliminaries are arranged, and will immediately proceed to pull down the building now cumbering the site and erect a new structure. In the meanwhile Sauborn's Long Room has been secured, Sanborn turning over the lease for one year, at a monthly rental of \$1,000.

The only outside stocks showing any animation at present are the Idaho stocks. If you can credit the local papers the strike in Gold Chariot is a valuable one, and consists of new vein not heretofore known. All the other Idaho keep up well in the market, and are beset with glowing reports. The Gold Chariot stock dividend comes this way. It will be remembered that the capital stock was recently increased from 30,000 to 90,000 shares, the par value remaining unchanged, namely \$100 per share. The trustees used 15,000 shares of the increased capital to liquidate some claims against the company. This makes 45,000 shares remaining of the new stock. It is to the holders of these shares that the stock dividend applies. The remaining 45,000 shares were divided pro rata among the present stockholders, 375 holders.

STOCKHOLDERS OF THE 27th INSTANT.

ANSWERS TO CORRESPONDENTS.

In answer to "Alphabetical," in your last issue, for a remedy for consumption in its first stages, I can recommend Dr. Pierce's "Golden Medical Discovery," if taken according to directions, for it has been thoroughly tried by my family, and the results were glorious. "Alphabetical" must not expect one bottle to do the work—my wife took three bottles before she could discover any change, but after the third bottle every dose seemed to strengthen the lungs, and now she is well and hearty. "Alphabetical" will write to me I will get answers to the above.

HENRY H. M. PATTON
Lawrence, Mariou Conuty, Ind.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

(FROM OFFICIAL REPORTS FOR THE MINING AND SOLENTI PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

By Special Dispatch, Dated Washington, D. C., May 25th, 1875.

FOR WEEK ENDING MAY 11TH, 1875.

WAGON-BRAKE BLOCK.—George G. Beckland, Milton, Cal.

FREEDER FOR TRESHING MACHINES.—Byron Jackson, Woodland, Cal.

DISTRIBUTOR FOR FREEDING BELTS OF TRESHING MACHINES.—Byron Jackson, Woodland, Cal.

FOLDING OAR-LOCK.—Augustus W. Thornton, of Oakland, Cal., and Martin Vice, of S. F., Cal.

ROASTING APPARATUS.—Louis Duterte, S. F., Cal.

PAYMENT.—Louis Duterte, S. F., Cal.

SINGLE RAIL RAILWAY CAR.—Chandler McWayne, Colfax, Cal.

BROOM-HANDLE SOCKET.—John H. Pitts, S. F., Cal.

TRADE-MARKS.

FOR WHISKY.—Lilienthal & Co., S. F., Cal.

FOR WATCHES.—John W. Tucker (two cases), S. F., Cal.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

General News Items.

The seat for Tipperary has been awarded to Moore, opponent of the late John Mitchell, on the ground that the latter was not entitled to an election, as he had forfeited his allegiance to the crown.

THE San Francisco Fire Petrol is now ready or duty.

Two earthquakes in Santa Berhere last week.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

SPRING CREEK DITCH & M. Co.—May 14. Trustees—P. H. Kramer, R. E. Brewster, E. Green, J. L. E. Kelly and Joseph Messinger. Capital, \$5,000,000. CON. COMPTON & S. M. Co.—May 14. Trustees—John Scario, Charles S. Peck, H. W. Plummer, F. W. Reynolds and Holland Smith. Capital, \$500,000.

CARDUETTER GAS MACHINE Co.—May 14. Trustees—Charles F. Webster, John O. Henderson, Marshall Pierce, F. E. Monteverde and D. P. Barstow. Capital, \$500,000. CON. COMPTON & S. M. Co.—May 14. Trustees—S. E. Holcombe, H. J. Craven, O. E. Bogert, W. W. Hickles and Dennis Heagerty. Capital, \$10,000,000.

HAMSTON M. Co.—Location: Eureka, Nev. Trustees—G. F. Lewton, S. P. Donney, Geo. F. Bragg, U. D. O'Sullivan and John A. Pastore. Capital stock, \$500,000.

KAN RIVER LAND AND CANAL Co.—May 20. Object: To construct a canal for water, more or less, and four feet deep, from a point on Kern river, near the railroad bridge, Kern county, extending thence to Tulare Lake, for irrigating, manufacturing, commercial and mining purposes; to buy and sell, lease and otherwise acquire lands and manage the same; to raise, buy and sell live stock, and generally to engage in every kind of business pertaining to canals, agricultural, timber, mineral or grazing lands. Trustees—W. H. Baxter, William Holden, J. P. Moore, O. P. Calloway, J. A. Robinson, Charles F. Brown and E. W. Scott. Capital stock, \$500,000; shares, \$100.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL, MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extractions of their Respective Metals without Quick Silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 143 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his speciality. Price \$2.50 coin, or \$3 currency, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Oold and Silver Ores generally, with 120 Lithographic Diagrams. 1867. This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, the most recent and successful methods of mining, Metallurgy, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO \$5.

Nevada and California Processes of Silver and Gold Extraction, for general use, and especially for the Mining Public of California and Nevada, with full explanations and directions for all metallurgical operations connected with silver and gold from a preliminary examination of the ore to the final casting of the ingot. Also, a description of the general metallurgy of silver ores. 1864.

As its title indicates, this work gives a wide range of information, applicable to all vein miners and workers in precious metals, affording hints and assistance of exceeding value to both the moderately informed and the most expert operator. Price, \$5 in cloth; \$6 in leather—coin.

BY OTHER AUTHORS.

The Quartz Operator's Hand-Book; by P. M. Randall. 1871. Revised and Enlarged Edition. Cloth bound, 175 pages. Price, \$2.

Sulphurets: What They Are, How Concentrated, How Assayed, and How Worked; with a Chapter on the Blow-Pipe Assay of Minerals. By Wm. M. Barstow, M. D. 1867. cloth bound, 114 pages. Printed and sold by DEWEY & CO., Price, \$1; postage free. The best written work, and most complete work on the subject treated. ANY OTHER BOOKS DESIRED will be furnished at the most reasonable rates by DEWEY & CO., Mining and Scientific Press Office, S. F.

The Large Circulation of the Mining and Scientific Press extends throughout

the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana, British Columbia and to other parts of North and South America. Established in 1860, it has long been the leading Mining Journal of the Continent. Its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

PACIFIC RURAL PRESS,

A first-class 16-page Agricultural Home Journal, filled with fresh, valuable and interesting reading. Every farmer and ruralist should take it. It is immensely popular. Subscription, \$4 a year.

DEWEY & CO., Publishers, No. 224 Sansome street, SAN FRANCISCO.

SUBSCRIBERS are requested to examine the printed address on their papers. If mistakes occur at any time, please return them to this office. The last figures (at the extreme right) represent the year that your subscription is paid to. Next to these the day and month is represented. For instance, your subscription being paid to July 4th, 1876, it would be represented, viz: 7-4-76; or 4/176; or July 4, 76.

UNITED STATES

Mineral Land Laws, Revised Statutes, And Instructions and Forms Under the Same.

We have just issued a pamphlet containing the general mineral land laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1860; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Register's Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Leases or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of MINING AND SCIENTIFIC PRESS, S. F.

N. B.—We have also added to the above publication, the REVISED STATUTES OF THE UNITED STATES, so far as relates to Mining Laws.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

Mining and Other Companies.

California Consolidated Mill and Mining Company.

Location of principal place of business, San Francisco, Cal. NOTICE.—There are delinquent upon the following described stock, on account of assessment levied on the 1st day of April, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

NAMES.	No. Certificate.	No. Shares.	Amount.
Burke, T.	33	100	\$ 50 00
Burke, T.	34	50	25 00
Burke, T.	35	50	25 00
Hendy, Joshua.	84	70	35 00
Hendy, Joshua, Trustee.	73	24,550	12,275 00
Hendy, Joshua, Trustee.	73	2,116	1,058 00
Kendon, John.	80	50	25 00

And in accordance with law, and an order of the Board of Directors, made on the 1st day of April, 1875, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of the company, 408 California street, room 10, on the 18th day of May, 1875, at the hour of 1 o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

J. W. TRIPP, Secretary. Office, Room 16, No. 408 California street, San Francisco, Cal.

POSTPONEMENT.—The above sale is postponed until Tuesday, the 15th day of June, 1875, at 2 o'clock P. M. By order of the Board of Directors. J. W. TRIPP, Secretary.

Carbon Coal Company—Principal place of business, San Francisco, California.

Location of principal place of business, Contra Costa County, California. NOTICE is hereby given, that at a meeting of the Board of Directors, held on the 1st day of May, 1875, an assessment of \$1.25 per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, N. O. Fassett, No. 220 Clay street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 1st day of June, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the 14th day of June, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

N. O. FARRETT, Secretary. Office, No. 220 Clay street, San Francisco, California.

Cordillera Gold and Silver Mining Company.

Location of principal place of business, San Francisco, Cal. Location of works, Morelos Mining District, State of Chihuahua, Mexico. NOTICE is hereby given, that at a meeting of the Board of Directors, held on the 8th instant, an assessment of Ten cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, No. 321 Washington street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 15th day of June, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the 30th day of June, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

HENRY R. REED, Secretary. Office, No. 321 Washington street, San Francisco, Cal.

Geneva Consolidated Silver Mining Company.

Principal place of business, City and County of San Francisco, State of California. Location of works, Cherry Creek Mining District, White Pine County, State of Nevada. NOTICE is hereby given, that at a meeting of the Board of Directors, held on the 18th day of May, 1875, an assessment of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, Room 14, 302 Montgomery street, San Francisco.

Any stock upon which this assessment shall remain unpaid on the 14th day of June, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 30th day of June, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

L. T. MILLIKEN, Secretary. Office, Room 14, 302 Montgomery street, San Francisco, Cal.

Nevada Land and Mining Company.

Location of principal place of business, San Francisco, California. Location of works, Spruce Mountain Mining District, Elko County, State of Nevada. NOTICE is hereby given, that at a meeting of the Board of Directors, held on the 14th day of May, 1875, an assessment (No. 17) of Two cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, Rooms 3 and 6, No. 302 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on Saturday, the 19th day of June, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the 18th day of July, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

WM. H. WATSON, Secretary. Office, Rooms 3 and 6, No. 302 Montgomery street, San Francisco, Cal.

Orleans Mining Company.—Location of principal place of business, San Francisco, California.

Location of works, Grass Valley Township, Nevada County, California. NOTICE is hereby given, that at a meeting of the Board of Trustees of said corporation, held on the 27th day of April, 1875, an assessment (No. 4) of one cent per share was levied upon the capital stock of said company, payable immediately, in gold coin of the United States of America, to the Secretary, at the office of the company, room 6, No. 315 California street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Tuesday, the 1st day of June, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the 22d day of June, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

GEO. E. THURSTON, Secretary. Office—Room 8, No. 315 California street, San Francisco, Cal.

Silver Sprout Mining Company.—Location of principal place of business, San Francisco, State of California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment levied on the seventeenth day of February, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

NAMES.	No. Certificate.	No. Shares.	Amount.
George Hearst.	42	2000	\$ 100 00
George Hearst.	83	580	29 00
John J. Mountain, Trustee.	66	100	5 00
John J. Mountain, Trustee.	67	100	5 00

and Hot Liqueur Pumps and Wine Pumps. Particular
attention paid to AIR PUMPS, also to

DIVERS' SUBMARINE PUMPS.

Artesian Well Pumps Made to Order.

Brass Castings Made to Order.

No. 222 FREMONT STREET, - - SAN FRANCISCO.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT
for DIAMOND POINTED DRILLS, now brought to the
highest state of perfection, are prepared to fill orders
for the IMPROVED PROSPECTING and TUNNELING
DRILLS, with or without power, at short notice, and
at reduced prices. Abundant testimony furnished of
the great economy and successful working of numerous
machines in operation in the quartz and gravel mines
on this coast. Circulars forwarded, and full informa-
tion given upon application.

VOLUME XXX
Number 23.

Short Lectures on Patents.

No. 7.—By Jno. L. Boone, of Dewey & Co's Mining and Scientific Press Patent Agency.

Caveats.

It is seldom that an inventor conceives an idea and at the same time conceives the best method of carrying it into effect. Usually the main idea comes first, and little by little the method of operation develops itself. The caveat is intended to protect the inventor during the period which ensues between the conception of the main idea and its embodiment in a practical form. Many inventors do not understand the real object and effect of a caveat and there are some persons who do not even pronounce it correctly. One person recently asked what it would cost to file a "cavis," another wanted to file a "cravat," and still another thought that he must file a "cavity" in order to secure his inventions. These Partingtonisms, however, are of rare occurrence.

A caveat is a document addressed to the Commissioner of Patents, giving notice that the caveator, or person who files the caveat, is engaged in experimenting upon a certain plan, method, system, device, machine or combination with a view to applying for a patent on the same when it is perfected, and the caveat must describe the manner in which it is proposed to accomplish the end, with sufficient accuracy to enable the office to understand what the caveator proposes to do, and how he proposes to do it. This having been done, the law provides that in case another person should, while the caveat is in existence, apply for a patent which would interfere with the rights of the caveator, the Commissioner shall suspend action upon the application, notify the caveator and require him to file his application for a patent within a specified time. The two applications being now on file, it is an easy matter to determine whether any conflict exists between them or not. If there is a conflict an interference is declared and the parties are required to produce proof as to when each one made the invention, and the one who proves priority takes the patent. To use a homely phrase, a caveat is a watch dog that barks when his master's rights are in danger.

When a caveat is placed on file, no examination is made by the Patent Office as to the novelty or patentability of the invention. It is placed in a pigeon hole ready for reference, and if no conflicting application is filed during the year that it remains in force, it is never heard from afterwards. A person might file a caveat on a device that has been in use for fifty years; the Patent Office would take the fee, file the caveat and let it lie until it runs out. While a caveat is on file no one but the Examiners in the office, the caveator himself, or a person duly authorized by him, is allowed to examine its contents, hence it is called a secret paper. Formerly the caveator was allowed credit for a portion of the caveat fee when he applied for his patent, but this provision has long been abolished, and now the filing of a caveat entails an expense which is entirely separate from the application for a patent.

An impression seems to have obtained amongst a large number of inventors that they can secure their inventions by simply paying the caveat fee into the United States Sub-Treasury in this city, and receiving therefor a receipt, without any other formality, and that such a proceeding is equivalent to filing a caveat. The Sub-Treasury has nothing whatever to do with patents or inventions. The inventor may purchase Sub-Treasury certificates for the purpose of forwarding them to the Patent Office in payment of Government fees simply as a convenience, but the Patent Office prefers a postal order. In order to secure the protection provided by law, the inventor must file his caveat in the Patent Office, and nowhere else. The caveat does not begin to take effect until all of the papers are duly filed. The Patent Office returns to the inventor an official receipt sealed with the seal of the Patent Office and signed by the commissioner, and until this receipt is dated, the caveat does not begin to take effect. It some times happens

that an examiner overlooks a caveat and grants a patent on the same invention to another party while a caveat is on file. When this is done the caveator must apply for a patent within a reasonable time and demand an interference with the patent which has been granted. The Patent Office does not hold itself responsible for such oversights. Some times a caveat is on file in one department of the office while the substance of the invention is embodied in an application which is acted upon in another department. In such a case it would be impossible for the examiner in one department to know about the caveat in the other department, and the patent would be granted. When this is the case, the caveator, if he diligently files his application, will not be prejudiced by the prior application, and the interference will proceed the same as if neither party had a patent.

two countries in which a caveat system exists. In England they have a provisional protection, which only protects the inventor for six months, but which does not begin to compare with our caveats. Too many inventors take advantage of the privilege of filing a caveat to protect them after they have completed and perfected their inventions, and when they ought to apply for patents. In such cases a caveat is liable to do more harm than good, because the inventor must make oath, in order to file a caveat, that his invention is not complete. This would give a showing of priority in favor of any person who subsequently filed an application for a patent and produced proof that he had completed the invention prior to the filing of the caveat.

The office of a caveat being to protect a crude and imperfect invention, it requires considera-

McFARLAND'S PATENT DRY ORE CRUSHER.

"A caveator who neglects to apply for a patent for more than a year after another has obtained a patent for the same invention is presumed not to have completed it." (Com.'s decision, Hildebrand, 1869). The ground upon which this decision was made, was that the grant and issue of a patent was a public act, and the caveator was bound to take notice of it and to file his application within a reasonable time thereafter.

The law only provides for the filing of a caveat for one year, but it can be refiled one year after another by paying the proper fee, but each renewal is considered as a new caveat and not as an extension of the old one. If a caveator allows his caveat to run out and another party subsequently obtains a patent for the same invention, the right of the caveator to make use of his caveat in a contest for priority depends upon his diligence in making his application, for if he should not make immediate application, his caveat cannot help him. "A caveat is a secret proceeding which can only benefit the caveator if diligently followed up by the completion of his invention and the filing of his application." (Com.'s decision, 1869.)

The expense of filing a caveat is comparatively small and the legal requirements are few, so that it constitutes a cheap and ready means of protection to the inventor and experimenter. It relieves his mind of the fear that his discovery or invention will be appropriated by some one else, and leaves him free to experiment and direct his energies to the work of improving and perfecting.

Canada and the United States are the only

ble skill in its preparation. An improperly constructed caveat is inoperative, and is worse than nothing. It lulls the inventor into a feeling of security, and the confidence that he places in it is often "a cloud that hides the progress of his enemy." When properly employed and skillfully filed a caveat is the inventor's safeguard; without it he would be like the crow in the fable of the crow and the fox. Let him but open his mouth to explain and Reynard grabs up the prize and is off.

THE STATISTICIAN.—The May number of this excellent hand book contains one noticeable feature. We refer to the complete, accurate and admirably arranged list of postoffices in California, Oregon, the Pacific Coast Territories and British Columbia. By consulting this list the inquirer can ascertain at a glance the time of the arrival and closing of mails for any desired point. The other tables and the general fund of useful information it contains make the *Statistician* indispensable to the business man.

HEALD'S STRAW BURNING ENGINES.—Mr. J. L. Heald, of Vallejo, is building six straw burning engines of the following dimensions: cylinder, eight inches, twelve inch stroke, and sixteen-horse power; boiler nine feet six inches long, forty inches diameter, a twenty-four inch main flue, thirty-two two and one-fourth inch tubes seven feet long. Engine bolted on to side of boiler. Sheave governor and improved heater; adjustable exhaust. Some of the boilers of steel.

A New Style of Dry Ore Crusher.

The illustration on this page represents a new method of crushing dry quartz, which has been patented by J. M. McFarland, of Virginia, Nevada. The device is a novel one, the salient features of which may be seen by a glance at the engraving. A large horizontal iron cylinder is provided, through which a shaft passes, having its bearings in a suitable frame. Inside of this cylinder is another smaller iron cylinder which is bolted at each end to the ends of the main cylinder, both rotating simultaneously by means of the same shaft. The inner cylinder has slots cut in it at intervals, in which are inserted small peculiarly shaped stamps, or bars of iron with a stump head at each end. The cylinder is arranged a suitable distance from the outer cylinder, so as to give the stamps the requisite fall. The stamps as they approach the vertical line slide in the cylinder and strike a blow in the ore, and are then forced around by the cylinder and have a grinding effect. They strike two blows at each revolution. They are arranged as close together as they can be and work well, and strike a great number of blows to each revolution.

The outside cylinder is the ore holder into which the ore is fed at one end through the hopper shaped spouts and discharges through holes at the other end on to a screen, which is arranged to separate the fine particles and carry the coarse portion back to the head of the ore holder, to be delivered to it again for reworking if necessary. The cylinder has sufficient inclination to cause the ore to pass to the discharge openings.

The stamps consist of bars with steel heads, the bars and heads being considerably longer than the diameter of the cylinder which carries them, and arranged in diametrical holes or mortises in it, so as to project from the surface as close together as they can and slide freely to strike the blows. They slide endwise and fall into the ore in the bottom of the outer cylinder whenever they approach the vertical line; the end sliding down and striking the ore remains until it arrives near the top of the cylinder, when the bar slides again and the other end falls on the ore, and so on. A beveled shoulder on the stamp keeps it in position in its mortise until just at the proper moment, when it drops on the ore.

The screen shown under the apparatus has a shaking motion communicated to it by means of the device shown at the end of the machine. A toothed wheel engages with a smaller one which operates a crank and rod, giving a lateral shaking motion to the screen.

In the revolution of the cylinder the coarse quartz will constantly roll over the fine, and even without the aid of the stamps this will tend to finely pulverize it. The stamps, however, keep continually dropping on the quartz passes under them, and this, with the attrition of particles caused by the revolution of the cylinder, serves to pulverize the quartz thoroughly. As the coarse quartz constantly rolls over the fine the stamps will work on the coarsest quartz and have a better effect than if dropping into a mass of coarse and fine quartz. The friction of cams against tappets is entirely avoided in this device.

This machine is very simple in construction and operation. The stamps are made in such a shape as to be easily replaced. None of these machines have been made as yet, but the inventor thinks of making the outside cylinder five or six feet in diameter and eight or ten feet long, with stamps to weigh from ten to three hundred pounds each, with a drop of eight or ten inches. The inventor will make liberal arrangements with parties who purchase rights. After full investigation and practical tests, he will give a free right to proper parties to make the first one. Those interested can address J. L. Tharp, Mining and Scientific Press office, where the working model can also be seen.

This year the southern counties of California, principally Los Angeles, sent to San Francisco 5,380,000 oranges, 620,000 lemons and 80,000 limes. The consumption of California is about 10,000,000 oranges a year, and 5,000,000 are brought from Mexico and the Pacific islands.

CORRESPONDENCE.

Mineral City Mines.

EDITORS PRESS.—Thinking a few lines from here might be interesting to some of your readers, I take the liberty of sending the following few items. Just at this time we are having a remarkably dull and gloomy time, not a stroke of work being done in the camp.

Last fall the Hayes mine was shut down, and although the indications and prospects were good, yet up to the present time work has not been resumed.

The Ward Ellis closed their work about this same time, and although the mine is perhaps as good, if not the best mine in the camp, they have quite a large pile of good smelting ore on the dump, and can extract plenty more very easily. It is a great pity this company have not got a furnace of their own. The Watson company, after expending several months' time, and a large amount of money, on their own mines working them, it is generally understood here, under the direction of some spiritual medium in San Francisco, and assisted by an expert with a crooked stick, or some other device that was supposed to turn or indicate where the rich bodies of ore were, finally had to abandon their mines, or at least are not doing anything on them at this time. To add to the disagreeableness of the situation their mill was burned lately by some incendiary. Up to the present time, no one has been arrested for the act, but suspicion points very strong to certain parties as the cause, and to one certain party as having applied the match.

I hardly think the company will ever do any more work here, as their mines do not look very encouraging, and the camp is flooded with their now useless checks, and the chances not very brilliant of their ever being redeemed.

Judge Welsh, of this place, has had a lease of the furnace and mines of the Canton company, and has been working the mines and smelting the ore for nearly a year, and I think with fair results.

The mines are certainly looking splendid and show a large amount of good smelting ore, that will pay well in silver. One of the mines will average thirty dollars per ton in silver and gold, and is rich in lead. Another, the Altman, is rich in gold, averaging at least \$100 per ton. Smelting was resumed this spring, after about three months' idleness, and all things bid fair for a season of activity and prosperity, but when the furnace was started it was under the foremanship of a totally incompetent person—one who probably had never helped charge a furnace. As a natural consequence, the lining of the furnace did not last more than half as long as it should have done, and from 250 to 300 bushels of coal was burned unnecessarily every day; besides, not more than three-fourths the usual amount of bullion was made.

At Ward District,

Some twenty-five miles from here, the mines are looking splendid. The Martin White company, under the management of Lloyd Frizell, are developing some really valuable mines. They have quite a large amount of good ore on the dump, and have shipped ten tons to San Francisco, to be tested at Selby's reduction works. If the working proves satisfactory, shipments will continue to be made until the company can complete suitable reduction works of their own.

Take all our disappointments and bad luck into consideration, and then look at our mines, and I think when we get good, substantial and honest men interested in our mines and furnaces, we will have the best mining camp in Eastern Nevada.

Mineral City, Nev., May 20th.

Affairs at Panamint.

The Panamint News says: We have all along taken the ground that the times in Panamint would change for the better, and that we should have as lively and prosperous a camp as there is on the coast. We confess, however, that we did not think we would so soon be prepared to say—in view of the vast amount of mill work to be done, and the great delay incident to the introduction of capital into a new camp—that we were so soon to experience that which is so greatly to be desired. Our prognostications are about to be verified. Indeed there is already a vast change to be noticed which has taken place within the last two or three weeks. Previous to that time men were seeking employment and could not obtain it, and they would leave the camp. Now employers are seeking men, and they are not to be had to satisfy the demand. Although quite a large number have come in within the past week or ten days, still there is a further and large demand for them—that is, for good miners. Considering the number of new companies that have been started, those about to commence and the near completion of the S. V. M. & Co.'s twenty stamp mill, which will necessitate the employment of a large number of miners to supply it with ore; also the fact that the lower mill will soon be capable of reducing a large amount—to say nothing of the projected sixty-stamp mill of the same company, as soon as their other two are completed and the new mill of the Sunrise

company—we think there will be quite a large demand for miners and mechanics for some time to come. The Surprise Valley company do not now labor under the disadvantages they experienced at first. Their mines are opened to an extent that a large force can be advantageously worked. Other companies will soon have theirs in like condition, and altogether we think the bright time for Panamint is near at hand, and many miners who are now idle in other places will here find employment at good wages. In fact they are wanted now.

About Arizona Mines.

The general mining outlook of our Territory, and especially of this county, is cheering. From every section we hear of good mines, new and old developing, and frequently see and feel the metallic substance.

Thus far our miners have worked with little means and without machinery or furnaces, and yet we do not know of a single man who is not pleased with his prospects. It is only a little more than one year since the promised peace with the Indians has been believed permanent, and in that short time great enterprises have been undertaken and carried to a point where success is now regarded as certain. Shafts have been sunk, cuts made, and tunnels driven into the mountains, revealing bodies of ore that bear a world of riches. And this good work goes bravely on. Nearly every range of mountains is filled with hardy prospectors, turning over the treasure bearing rocks, bringing to light new veins and preparing for the day when extensive reduction works will enable them to receive a good return for their present labors.

The growth of mining countries, except where gold placers exist, is generally slow but certain, if good metallic veins are found. It takes years of patient toil to develop a mine so that it is ready for the machinery, and especially is this the case in a Territory so remote as Arizona is from the mining and monetary centers.

Had Congress granted us a railroad, our situation would have been second to none of the mining empires growing up on the Pacific coast. As it is, we must still work on hopelessly, saying that we may reap, knowing that we have in lavish abundance the elements of a golden future and that the better day so long hoped for is not so far away as many would have us believe.

The Ostrich mine will soon have its mill completed, and then we will have a goodly abundance of gold from that section. The small Mexican furnaces keep producing a quantity of silver bullion sufficient for necessary expenses, at the same time developing the mines.

Copper ores are shipped that pay over \$100 per ton profit, and are not these facts in themselves suggestive of what can and will be done when capital takes hold.

Very many sit down and indulge in gloomy thoughts, wondering why capital does not come, when it is barely possible that no effort has been made to make capital acquainted with the metallic wealth of the country—never wrote a word, sent a paper or a piece of rock outside the limits of their own horizon. It is to be supposed that capitalists learn by inspiration of the splendid opportunities for investments in mines, or are they to learn by the same channels of information in which we have been working for years? It is the duty of every person who desires the welfare of Arizona to send abroad by every conceivable source all we know of the vast resources of our Territory, and let it be known among every class and condition of men on the earth that Arizona is without a peer in her capacity for the production of the precious metals. There should be organized effort to publish plain truths of our fertile valleys, where large colonies could find pleasant homes; of our almost illimitable grazing facilities; of our matchless climate and our gigantic mines. When it is known, as we who live here know and understand it, there will be no more complaints of neglect by those who are seeking a place to put their money where it will do the most good. We need more money and more muscle to develop Arizona, and these we can have very soon if we publish more fully to the world what fortune lies within easy grasp in the near future. —Arizona Citizen.

THE GRAVE OF COMSTOCK.—We commend to the owners of the Comstock lode the following from the Bozeman Courier, and trust that it may meet with favorable consideration. A portion of their great wealth could not be more appropriately spent than in commemorating in marble or granite the man who made them great through his discovery, even though he died in Montana, a penniless wanderer. "The grave of Comstock, the famous discoverer of the great ledge in the State of Nevada which bears his name, from which over three hundred millions of dollars have already been extracted, and in which another three hundred millions is said to be 'in sight,' the grave of this great and now historic miner, is in a neglected spot, in the Bozeman cemetery, and unmarked by even a head-board. What say the owners of the great bonanzas to this? From the millions at their ready command, would it not be well for them to contribute a few thousand to place a commemorative stone over the renowned prospector's remains?"

The Santa Cruz Sentinel states that the surveyors have commenced operations at Half Moon bay for the coast narrow gauge railroad from San Francisco to Santa Cruz.

Calaveras Gravel Mines.

The Calaveras Chronicle says: A visit to the gravel mining enterprises in this vicinity furnishes ocular demonstration of the fact that unusual activity is being evinced in operations of that character. There is still no diminution of the water supply; and miners appear determined that a drop of the fluid shan't run to waste. Owing to the fact that much less than the usual quantity of snow fell in the mountains last winter, miners are haunted with fears of an early failure of water and are putting in their best "licks" while they have a chance. In the great Happy valley hydraulic work goes on uninterruptedly. Although a good deal of piping has been done the claim is not yet fairly opened, work, so far, being restricted to the purpose of putting the mine in proper shape for the extensive operations contemplated in the future. A vast amount of labor has been required in outfitting a lengthy ground-sluice, through solid bed rock, and laying about a mile of flume. All the preliminary work is now done with the exception of running a bed rock tunnel from the head of the ground sluice to the gravel bank, an undertaking that will be pushed as fast as possible. The tunnel will be three hundred and fifty feet in length, and its completion will put the mine in admirable condition for working. The claim is of sufficient magnitude to last for years, and the prospects are that it will prove very remunerative.

Cook & Co., proprietors of Sport Hill hydraulic, are pushing things with their usual energy and vim. The completion of a bed rock tunnel, for the reception of their flume, has given them plenty of fall and an excellent dump, and they are now trying to see how fast they can transfer the hill to the gulch below. The mine is skillfully managed, systematically worked, and, best of all, paying handsomely. The company have ground enough to keep them employed for years, rapidly as they are working it.

Moser, owner of Spring Gulch sluicing claim, is continuing operations with unvarying success. He has washed a hole through the immense deposit of tailings in the gulch as broad as the Apian way, and will ultimately clean the entire ravine out down to the bed rock. From two to three thousand inches of water are used in the operation, the supply being stored in a reservoir at the head of the gulch. The enterprise pays, about \$25,000 having already been taken out.

Veith, the enthusiastic Tunnel ridge annihilator, with a big head of water under an immense pressure, is literally making the gravel fly. The ridge is disappearing like a snow bank under a summer's sun. The gravel bank is so deep—115 feet—that it has been found expedient to use two streams of water, one for running off the top and the other for washing up the bottom. Water is brought to the mine in iron pipes, under a pressure of about 250 feet, and directed against the bank through "Little Giant" nozzles. The mine is also supplied with two strings of flume to accommodate the different streams of water used. At present attention is principally directed to running off the top, although a strong force of hands is engaged cleaning up bottom. The claim is one of the most extensive in the country. At the famous Duryea hydraulic, in Chille gulch, work is going on with that persistent continuity which has characterized operations since Mr. Duryea became proprietor of the mine. Three hundred inches of water, having a pressure of about two hundred and sixty feet, are daily used, and none of the appliances known in modern hydraulics are lacking. Although acres upon acres of the gravel deposit have been washed away, there is no diminution of the yield of the mine, and we believe it will continue to pay for years to come. There is probably no other gravel claim in the middle or southern mines whose aggregate yield equals that of the Duryea, and the amount total is being largely swelled at every "clean-up." We wish the county could boast of a dozen such claims as the Duryea hydraulic.

There are a number of smaller hydraulics along the ridge—Collins', Henry's and McCann's—in all of which work is actively going on with good results. The tunnel claims of Bracket & Co., Brown and Quere are also being steadily and remuneratively worked.

The Red Hill hydraulic, under the management of Mr. Hayward, is an enterprise entitled to take rank among our most notable gravel mines. It has required a considerable outlay of labor and money to get ready to work the claim, but it is now in full blast and we don't believe it will be behind any of the others in point of yield. Water is conducted to the diggings through an 11-inch iron pipe a mile in length, obtaining, at that distance, a pressure of 160 feet. The gravel is easily piped, and as a large head of water is used washing goes on rapidly. All the claims of which we have spoken are within a radius of two miles of Mokelumne Hill.

TIN IN POWDER.—A French journal gives the following method of preparing tin for tinning brass, copper, and iron: Melt the metal in a crucible which has previously been slightly warmed, and at the moment the metal begins to set, and when it is very brittle, pound it up rapidly, and when quite cold pass it through a sieve to remove any large particles that may remain.

The Petaluma Argus is informed that the Marin narrow gauge railroad has more business on the southern half of the line than it can perform with its present rolling stock.

A Mine in a Post Hole.

The Transcript, Nevada City, Cal., in speaking of the Schmidt mine says: About a mile or two from town, on the slope of Woods' ravine, embracing about twenty-five or thirty acres, is the ranch and mine of John Schmidt. This ranch was formerly owned by a Mr. Prescott, and in early days was known as the Rising Sun ranch. About three years ago Prescott sold it to the present owner for about a couple of hundred dollars. Mr. Prescott had planted about 2,000 grape vines, a number of fruit trees and blackberry bushes, and had a fine spring of water for irrigating purposes. Several acres were planted in clover, from which he ripened two and sometimes three crops a year. A comfortable house with three rooms made him a cozy little home, and the produce of the ranch made a good living for him. But Mr. Prescott was getting along in years, and feeling the infirmities of age stealing upon him, he disposed of his little ranch for a mere song, and went back to his friends in the Atlantic States, where he has since paid the last debt, and gone to his final reward; for he was a good old man, and had the respect of all who knew him. Shortly after the purchase of the ranch by Mr. Schmidt, who intended to move out there with his family, he employed his sons in digging holes and planting trees and vines. While engaged in this branch of industry, one of the boys, while digging a hole about two feet deep, struck upon a quartz ledge. More through curiosity than any expectation to discover a rich mine, the boy shoveled out the dirt, and picked out a chunk of the quartz, which, upon being examined, was found to be well sprinkled with gold. Calling his father he informed him of his discovery, and the work of taking out the rock was commenced in earnest. As piece after piece of rock was taken out, their hearts fairly danced within them to see such a rich pocket of gold and quartz. In a short time several hundred dollars worth of quartz specimens were extracted. Preparations for working the ledge in a proper manner were then commenced, and from that time to the present the ledge has been good paying property. Hoisting works have been erected, which have all been paid for, and we presume "Uncle Johnny" and his boys have a few twenties laid away for nest eggs. There are now sixty-six tons of first-class rock at the Pennsylvania mill waiting to be crushed, and several tons more are on the dump pile at the mine. The ledge at the bottom of the incline, which is down 120 feet, is about two feet thick, and shows quite freely in gold. The ledge runs nearly the entire length of the ranch before crossing on to other property, so it is a safe prediction that the Schmidt family have a good thing for a lifetime. How true is the old adage, "It is better to be born lucky than rich."

ORIGIN OF THE NITRE BEDS OF PERU.—The nitre districts of Peru form a plateau of a mean elevation of 7000 feet, fifteen to twenty leagues broad, and several hundred in length. Antony Guayard, in the *Monteur Scientifique*, proposes the following theory to account for its formation. He supposes that there has been an epoch when nitrogen compounds were disengaged from the volcanoes, just as there were porphyritic mountains, which have given rise to the beds of kaolin and other clays. In general, the saltpetre exists in the form of saccharoid deposits, composed principally of nitrate of soda and chloride of sodium, mixed with nitrate and iodate of potash, chlorides of magnesium, aluminum and calcium, sulphate of lime, magnesia and alumina. The earthquakes of these regions he considers to be subterranean electric storms. The author opposes the view that the nitre beds are derived from decomposed gneiss and the iodates from seaweeds. He has also shown that the coloring matter of the nitre beds is not of organic origin, the yellow being chromic acid and the violet manganic

A LIGHT WITHOUT FIRE.—In Paris, the watchmen in all magazines where inflammable or explosive materials are stored, use for purposes of illumination a light provided according to the following method: Take an oblong vial of the cleanest glass; put into it a piece of phosphorus about the size of a pea, upon which pour some olive oil heated to a boiling point, filling the vial about one-third full, and then close the vial with a tight cork. To use it, remove the cork, and allow the air to enter the vial, and then re-cork it. The whole empty space in the bottom will then become luminous, and the light obtained will be equal to that of a lamp. As soon as the light grows weak, its power can be increased by opening the vial and allowing a fresh supply of air to enter. In winter it is sometimes necessary to heat the vial between the hands to increase the fluidity of the oil. Thus prepared, the vial may be used for six months.

IMPROVED FREIGHT CAR.—The Banlet manufacturing company, Laconia, New Hampshire, have constructed a freight car which can safely carry two tons of freight to one of dead weight, the reverse of which is true of ordinary freight cars. The body of the car is supported upon one truck of six wheels.

AN EXHIBITION of all kinds of railway carriages in use throughout the world is about to be held in New York, with numerous drawings and models of everything appertaining to progression by steam.

SCIENTIFIC PROGRESS.

Sensations Produced by a Lightning Stroke.

A correspondent of the *American Artisan* furnishes the following with regard to the effects of a lightning stroke: Of the three, my wife only was "struck," and fell to the ground, my son and myself remaining erect, and all three retaining consciousness. For more than half an hour my wife lost the use of her lower limbs and left hand, both of which became rigid. From the feet to the knee she was splashed with rose-colored, tree-like marks, branching upwards, while a large tree-like mark, with six principle branches diverging from a common center, thirteen inches in its largest diameter, and bright rose-red, covered the body. None of us are certain of having seen the flash, and my wife is sure she saw nothing. As to the noise, my wife heard a "hollowing" sound and a "squish," recalling fire works; my son also heard a "hollow," while I seemed conscious of a sharp explosion. My wife describes her feeling as that of "dying away gently into darkness," and being roused by a tremendous blow on the body, where the chief mark was afterwards found. My son and myself were conscious of a sudden and terrific general disturbance, and he affirms that he received a severe and distinct electric shock in both legs. My left arm, shoulder and throat especially suffered violent disturbance, but I did not think it was electrical. As I turned to help my wife, who was on the ground, I shouted, as I thought, that I was unhurt, and hoped they were also; but it seems I only uttered inarticulate sounds, and my son, in his first attempt to answer, did the same. This, however, was only momentary; in an instant we both spoke plainly.

Neither of us referred the occurrence immediately to its true cause, but the idea of being fired at was present to all our minds; my wife, indeed, remained of the opinion that she was shot through the body, until she heard me speak of lightning. An infinitesimal lapse of time enabled my son and myself to recognize lightning; but I cannot say whether I did so before or after my first glimpse of the wreck on the ground. Neither of us saw or heard the mass fall, though it descended fifty feet, and fell on hard gravel close to us. My son and myself both experienced a momentary feeling of intense anger against some "person or persons unknown," further showing that we had primarily referred the shock to some conscious agency. I ought perhaps to add that neither of us felt any sensation of fear at the time; but we were all very nervous for several days thereafter.

DIAMONDS FROM SUGAR.—A French chemist has so succeeded in his experiments as to have reasonable hopes of producing at least black diamonds, if not colorless ones, from sugar. He has already obtained a carbon cylinder hard enough to cut glass, by exposing the perfectly burned sugar to a temperature of 1,800 degrees Fahrenheit in a closed vessel without access of air. It will be an interesting development, as far as regards the production of sugar-yielding crops; if this experimenter, shall succeed fully in his designs, and cane and beets come to be grown with a view to their final transformation into diamonds. Truly we are living in a wonderful age.

INTERESTING DISCOVERY.—Prof. Crookes had demonstrated that direct mechanical effect can be produced by light when luminous rays are allowed to fall upon one end of a most delicately balanced lever arm suspended in vacuum; the contrary has hitherto been assumed. Experiments suggested by this discovery have been made, tending to show the cause of the revolution of planets on their axes. Dr. Crookes has demonstrated by experiment that a number of discs, arranged in a certain manner in *vacuo* can be made to revolve by throwing upon them a pencil of light, and the rapidity of revolution is in proportion to the intensity of the light.

THE EVAPORATION OF METALS BY ELECTRICITY.—Mr. Hopkine describes an interesting experiment, which consists in passing a charge of electricity through a very fine thread of platinum, or other metallic foil, the thread being kept in place between slides of microscope glass. The effect of the heat from the electric discharge is to vaporize the metal, which is instantly condensed in a transparent layer upon the cold glass, which can then be studied by the microscope, and can be used in various ways to determine the character of the metal and the peculiarities of the discharge.

INTERESTING FACT.—A small elliptical ring of silver is heated to redness and then dipped in a beaker full of water; at first there is no sound heard, and for five or six seconds the silver remains visibly red hot under the surface of the water; suddenly there occurs a violent explosion, which sends the water in every direction, and usually breaks the beaker.

INTERESTING ARCHEOLOGICAL DISCOVERY.—An interesting discovery of what is supposed to have been once a pagan cemetery has been made in the sand hills of Finner, between Ballyshannon and Bundoran. The remains found consist of human bones (many of them corroded), ashes, skulls in good preservation, charcoal, and a cinerary urn.

Magnetism of Railways.

M. Heyl, engineer of one of the German railways, in a recent report upon the development of magnetism in the rails on railways, says: I have observed that all the rails are transformed at their extremities, after they have been placed in position a few days, into powerful magnets, capable of attracting and of retaining a key, or even a heavier piece of metallic iron. These rails preserve their magnetism even after they have been removed, but they lose it gradually. When in position, however, the magnetism is latent, only becoming free when the chairs are removed and disappearing again when they are replaced. Hence it is necessary to assume that two opposite poles come together at each junction, and that each rail is a magnet, the poles being alternately reversed throughout the line. This production of magnetism in the rails examined is undoubtedly attributable to the running of the trains and to the shocks, frictions, etc., thereby produced. The hypothesis of electric currents, induced or direct, must be rejected, since it is negated by experiments upon the subject made with suitable apparatus. Although the interest attaching to the fact above stated is at present purely scientific, it is not impossible that the magnetism thus developed may exercise an influence actually beneficial upon the stability of the roadway, increasing the adherence to the rails and the friction. It is possible, also, that the magnetic current may be stronger at the moment of the passage of the trains, than either before or after. If this be so, the observations may acquire a still higher practical importance.

A BOILING LAKE.—Mr. Joseph Sturge, of Birmingham, announces that a discovery of some considerable scientific interest has been made in the Island of Dominica. Drs. Freeland and Nicholls, Captain Gardner, and Mr. Watt, exploring the steep and forest covered mountain behind the town of Roseau, came upon a boiling lake about 2,500 feet above the sea level, and two miles in circumference. When the wind cleared away for a moment the clouds of sulphurous steam with which the lake was covered, a mound of water was seen ten feet higher than the general level, and caused by ebullition. The margin of the lake consisted of beds of sulphur, and its overflowing found exit by a waterfall of great height.

STEEL VS. IRON RAILS.—The *Railroad Gazette*, of New York, publishes a cent representing the wear on a steel rail, laid down in 1865, on the single main track in Clark street, Chicago, already alluded to in these columns, where nearly all the trains of the Chicago, Rock Island and Pacific and the Lake Shore and Michigan Southern railroads passed over it, and where engines were constantly shifting. Iron rails in similar positions were renewed as often as once in six months, the steel rails having outworn sixteen of the iron rail. The steel rail was gradually worn down on one side, but there was no splintering, as in iron rails.

UTILIZING WAVE POWER.—H. A. Bonneville, of London, England, has patented a new device for utilizing the power of the waves for propulsion of vessels and for other purposes. The invention consists of a series of floats distributed over a sea-going vessel, and connected with plungers of air pumps intended to compress the air in a receiver, the floats being raised or lowered by the action of the waves, and the air thus accumulated being used for the purpose of driving an air engine or as an auxiliary in driving a steam engine.

TRIUMPHS OF SCIENCE.—A candle 13,000 feet distant shines with a light twenty thousand times more brilliant than do some nebulae. Yet the constitution of the nebulae has been determined. They are found to consist of hydrogen and nitrogen. We know the nature of worlds situated at a distance inconceivable. And the relative ages of the stars we know. The white stars are the hottest and the youngest. The yellow stars, including the sun, are older; while the colored stars are not so hot, and are still older.

PROGRESS OF RUSSIA IN MANUFACTURES AND ARTS.—At the London International Exhibition, of 1872, the singular fact was made manifest that the Russian paper makers surpassed all others in the beauty, strength and variety of the products of their skill. In commercial printing and chromo-lithography, also, Russia stood at the head, showing that the military greatness of that nation is not its only title to respect.

HYDROGEN GAS IN IRON.—MM. Troost and Haufenille, of the Ecole Normale, who are studying the combinations of hydrogen with the metals, have observed that gas exists in ordinary pig iron to the extent of twelve volumes, and in manganese pig to the extent of twenty-seven volumes. M. Deville attributes the projection of sparks from molten iron to the jets of gas.

The meeting of the British Social Science Association will be held at Brighton in October next, and there will be an exhibition of appliances and apparatus relating to the sanitary and educational systems.

AMERICAN IRON SHIP BUILDING.—Twenty-three iron vessels were built in the United States last year, representing 33,097 tons—an average of 1,439 tons for each vessel.

MECHANICAL PROGRESS.

What Steel is.

Mr. Wm. Hackney has the following to say on this much beset question: Steel might then be defined as any variety of iron that was cast into a malleable mass; and the two parallel series, the irons and the steels, might be classified as follows:

PERCENTAGE OF CARBON.			
0 to 0.2	0.2 to 0.35	0.35 to 0.65	0.65 to 1.50 or more.
SERIES OF THE IRONS.			
Ordinary irons.	Granular irons.	Steely irons, or soft puddled steels.	Hard puddled steels. Cemented steel. Styrian steel.

SERIES OF THE STEELS.
Ex. soft steels | Soft steels | H' or S' steels | Hard steels

Steel was made by producing a melted alloy of iron, containing a smaller proportion of carbon or other hardening elements than cast iron. Practical steel making processes were of three kinds—(a) Fusion in crucibles, producing crucible steel. (b) Blowing air through melted cast iron, producing Bessemer steel. (c) Fusion on the open hearth of a reverberatory furnace, producing Siemens or Siemens-Martin steel. Fusion in crucibles was the simplest and oldest mode of making steel, and had been practiced by the Hindoos from a remote period. In the Hindoo process wrought iron was melted in small crucibles, with one-tenth of its weight of dried wood, producing a very hard steel, with upwards of 1.6 per cent of carbon.

Steel in Europe.

It did not appear that any mode of making true steel was known in Europe before the last century. Reaumur announced in 1722 that he had made steel by melting together from one-fourth to one-third of malleable iron with cast iron, in a common forge, and Huntsman, between 1750 and 1770, succeeded in making steel by melting cemented or converted bar iron. Since Huntsman's time the processes of crucible steel-making have been improved only in points of detail, and by the trial or practical use of all the different materials for melting that an advancing knowledge of chemistry had suggested as capable of producing steel. Malleable iron was melted by itself if it was of the hardness needed to produce the required quality of steel, or it was mixed with carbon or cast iron, if too soft, or with oxide of iron or of manganese, if too hard; and spongy reduced iron, or iron ore, was melted with carbon or with cast iron.

Experiments on Steel—Magnetism and Carbon.

At a recent meeting of the French Academy of Science, M. Treve communicated the result of the researches he had undertaken with M. Durassier on the relations which exist between the nature of steels and their coercive force. M. Durassier prepared fifteen bars of steel, divided into five series, differently carburized, of three bars, each one of which had been tempered in a distinct and especial manner. M. Treve magnetized these by saturation, and determined their magnetic force by the method of deflection. The bar docted with carbon to 0.95 per cent, and tempered with cold water, caused a maximum of deflection represented by 47. The bar containing the same percentage of carbon, but tempered with boiling water, gave 44. The bar containing the same amount of carbon, but tempered in oil, at 10 deg., centigrade (50 deg. Fah.) gave 43. The influence of the liquid used for tempering is, therefore, manifest. The influence of the percentage of carbon in each bar is not less, for the bar containing 0.95 per cent, gives a maximum of 47, while that containing 0.25 per cent, only gives 13. In preparing diagrams of variations for the different series of bars, the influence of the percentage of carbon and the tempering liquid became manifest. It was remarked, however, that, at the top of the scale in carbon, the nature of the tempering liquid no longer exerted a very marked influence; 47, 44 and 43 are very near one to the other; coercive force is but little manifest in steels whose percentage of carbon exceeds from 0.5 to 0.55 per cent. Another remarkable fact is the similarity of the magnetic curves and curves of elasticity of the bars. Carbon gives elasticity to the steel, and, at the same time, a capacity for magnetism.

TO PREVENT CARS JUMPING FROM THE TRACK. To prevent the numerous accidents to which railroad trains are liable from one car jumping the track, it is proposed to apply to cars a kind of shoe, consisting of a clamp-like arrangement which is affixed between the wheels of each truck. This runs about two inches above the rail, and if anything happens to throw the wheels from the track, the clamp at once grasps the rails, holds the car on the track, and brings the train to a speedy halt. Such a shoe will, it is claimed, prove a great saving of railroad rolling stock, and will add greatly to the strength of the truck, it being constructed of iron and weighing 500 pounds. It is found by experiments made with care provided with this device that the arrangement secures perfect safety against the class of accidents it is designed to meet, and it is also estimated that on account of this additional strength which each an attachment must necessarily supply, a car must last twice as long, on an average, with as without it.

Steam.

Steam, says Cassell's *Technical Educator*, in most of its properties resembles a gas, and, like any gas, expands on the application of heat to it. If, then, the steam be exposed to a high temperature, either its volume or its pressure will be increased, and a greater mechanical effect may therefore be obtained from it. Another advantage is also obtained by superheating the steam. Under ordinary circumstances, when the steam is not at a very high temperature it is partly condensed by contact with the cylinder and other working parts; and hence there is a deposit of water in them, and a corresponding loss of power. A few years ago the tendency was to superheat the steam as much as possible. It was found, however, that if its temperature be raised above 315°, the packing of the stuffing boxes is liable to become charred, and the oil or other lubricant used in the engine to be injured. The practice, therefore, seems to be gradually diminishing, and is not usually carried much beyond the degree that is requisite to render the steam thoroughly dry. Very many different forms of superheaters have been proposed and tried with varying degrees of success. The usual plan is to cause the steam to pass through a series of tubes placed at the lower part of the chimney, so that the heat employed is that which would otherwise escape with the smoke. It is not found that when fresh fuel has to be employed any advantage is gained by employing it in superheating the steam, instead of applying it to the boiler in the ordinary manner. In connection with the above we append the following in relation to the oil from exhaust steam from the Query department of the *Scientific American*: We have been thinking of using our exhaust steam by turning it into a tank containing cold spring water, thereby heating our supply water and saving fuel. We have been advised by experienced men not to do so, as they say we should burn out our boiler in a short time; they claim that the grease contained in the exhaust steam would form into globules, which would sink to the bottom of the boiler and prevent the water from touching the plates, thereby burning them out, and that they know this by actual experience with lake water in Chicago. With hard water or water containing much lime, it might be feasible; but with spring or soft water, it would be disastrous. Are these opinions sound? The journal addressed says in reply: There would not be much danger unless you use a very large amount of grease in the cylinder. In nearly all ocean steamers the condensed steam is used for feed water. With a proper oil cup, the amount of lubricant need in the cylinder is very small, and is as effective as a much larger quantity admitted carelessly. It is not well to use tallow in such a case.

MAGNET FOR IRON AND OTHER MATERIALS.—The following is the composition invented by M. L. Machabes, which is said to prevent iron from rust, and also to be applicable to other materials, such as stone or wood, used in conjunction with iron or other metal, in the formation of reservoirs or other works: Virgin wax, 100 parts; Galipoli, 125; Norwegian pitch, 200; grease, 100; bitumen of Judea, 100; gutta-percha, 235; red lead, 120; and white lead, twenty parts; all of which, says the inventor, have their special value. The materials are mixed in a boiler in the order in which they are given, the gutta-percha being cut up in small pieces, or rasped. The mixture must be well stirred at each addition, and when homogeneous is poured into moulds, and looks like chocolate. When used for preserving iron from rust, it is melted and laid on with a brush; but for stopping holes, etc., it must be in a pasty state. It may also be used as a glue, to fix a piece of metal over a hole. For certain purposes, such as stopping holes in large vertical metal surfaces, the composition is slightly varied, the Galipoli being reduced to 115, the bitumen to ninety, and the red lead to 100, while forty parts of gam oopal are added next to the gutta-percha.

CHANNELLED NAILS.—Nails made from round wire have always been complained of as breaking the wood, and a French manufacturer named Chelot has introduced an improvement in this article. He makes the nails of wire which is channelled, or polygonal, either by drawing or rolling, and their use has become considerable within a few months, they having been adopted in public works, after experiments made by the Government engineers. The report made by these gentlemen says that the weight of the channelled nails is from 12 to 15 per cent. less than those of the same gauge made from round wire; that the former hold 20 per cent. better in deal and 35 per cent. better in oak than the latter; that the former injure the wood much less. The economy is about 12 per cent., with the other advantages mentioned. The new nails, like the old, may be made from any kind of iron. The manufacture is about to be undertaken by a company, on a large scale.

CASTING STEEL.—At the steel works of Erment, France, the method adopted for steel castings is to connect the orifices of all the molds with a canal in which the molten metal is run from the furnace. The canal is furnished with doors or partitions, inserted lightly in the sand, which allow of the molds being filled successively, or as otherwise desired, by only removing the partition from one mold when the preceding mold is full.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

TARSHISH.—*Alpine Chronicle*, May 29: We are glad to learn that the hitch in the negotiation for leasing the Tarshish mine and mill to New York parties has been unraveled, and that work will soon be resumed and the mine pushed to a development. The mill is being put in order by direction of Mr. Vance, the lessee, who is expected to arrive at Monitor on next Wednesday to take possession of the property.

BUTTE.

THE LAVA BEDS.—The Chinamen are again buying up whatever pieces of mining ground they can get hold of in the vicinity of the Lava beds, or about town. Tuesday, George Miller & Co. sold a small piece, just out of town and near the Depot house, 132 by 273 feet for the sum of \$2,000. J. M. Bart sold a small claim, of half an acre, for the sum of \$500; also another small claim of less than half an acre, for \$150. Five years ago it would have been a difficult job to get \$10 for all three of the pieces. Within the next few months quite a large number of claims will be sold at equally good prices. There is mining ground enough about town to last for years yet to come, and it will pay well for washing.

CALAVERAS.

FAVORABLE PROSPECTS.—*Calaveras Chronicle*, May 28: Messrs. Lewis & Fairchild, who some time since located a mine near Leavitt's ranch, in the Mosquito district, are obtaining the most favorable prospects. The shaft on the mine is sunk to the depth of about 70 ft., developing a vein of first-grade ore, averaging about 30 inches in thickness. They have about 50 tons of very rich rock now in the dumps, and are rapidly increasing the quantity by stoping. A crushing of the rock previously taken from the surface down to the depth of 20 ft. yielded an average of \$40 per ton. All indications point to the permanency of the ledge, and it is probable that the next crushing will make even a better showing than the first.

RICH QUARTZ.—Charles Rickman, who recently located a quartz ledge in the suburbs of the town of Mosquito, is taking out excellent rock. No great depth has yet been reached on the vein, but the quartz will pay handsomely from the top down.

SAN BRUNO.—Stoping has been commenced in the San Bruno mine at Mosquito gulch. Rock of extraordinary richness is being taken out, samples of which have been shown us. The ledge averages about two feet in width, all high grade ore. The machinery works first-rate and operations are being pushed forward with vigor.

WOODS MINE.—We hear very favorable reports of the Woods mine, located in Washington district, near Sheep ranch. The ledge is from 12 to 14 ft. in width, composed of quartz of extraordinary richness. There is a shaft sunk on the ledge to the depth of about 100 ft. Work is being pressed zealously forward. The rock taken out is hauled to a mill owned in connection with the mine and crushed, the average yield per ton being well up in figures.

WEST POINT.—Times were never livelier in West Point than at the present, nor the prospects for the future more flattering. Work upon all the principal mines in the district—the Champion, Josephine, Mina Rios, Lone Star, Good Faith, Anderson Flat and others—is being urged forward with encouraging results, and the area of development is being steadily enlarged. Capital is extending a liberal hand in promoting the mineral interests of the district, and labor is stimulated by the degree of success that is rewarding its efforts upon every hand. No other portion of the county is making so good a showing as West Point, so far as quartz mining is concerned, and there is no question but that the permanency of a number of promising mines in that district will be definitely settled within the present year. All the mills in the district are now employed to their fullest capacity, and the erection of others is in contemplation.

INYO.

PANAMINT DISTRICT ITEMS.—*Panamint News*, May 25: Our report this week is from notes furnished us by Mr. R. M. Wilson, a civil and mining engineer of much experience on this coast, who recently arrived here for the purpose of examining our mines and to make surveys for the Panamint Consolidated mining company. We gladly give place to his opinions, as having had several years' acquaintance with him, we know he is much more competent to judge of the merits or demerits of mines than we are. So far he has visited but three mines.

WYOMINO.—In all the levels and winzes which he went through and carefully examined, he finds that our description of that mine in last Tuesday's issue is remarkably accurate. The Crystal drift, he says, has greatly improved since that time. He traced the rich ore chert from the croppings down to the lowest level in the mine, a distance of 300 ft., and finds it continuous and unbroken, and feels confident that as the center of the ridge is approached a much larger body of ore will be found. The mine is now so well developed by levels and winzes that a large number of men can be put to work in stoping, and unlimited

quantities of ore can be extracted, as soon as they are ready for crushing.

THE HEMLOCK.—What struck him forcibly were its smooth and well defined walls, which are shown to a depth of 200 ft., without a break or fault, the vein being well charged with ore of a very high grade. He had heard some pretty big stories of the Panamint country, but was astonished to find such mines, and it is his opinion that the Wyoming and the Hemlock are of themselves sufficient to make a good camp.

THE JACOB'S WONDER.—The west winze, from Rich gulch, is now down over 85 ft. from the lower level, making a depth, from the highest croppings of the ledge, of 500 ft. At this depth a rich body of ore, over 4 ft. in width, is developed. A large amount of ore can now be stepped from the bottom to the surface in this winze. The walls show great regularity, and there is convincing proof that the Wonder is a true fissure vein, and he has not a doubt but that it will be developed into a first-class mine. Mr. Wilson is agreeably surprised both in the appearance and developments in these three mines.

NORTH STAR.—Since last report the tunnel on this mine has been run in some 20 ft. further, making a total distance of 70 ft., and cutting into the ledge about 6 ft.; this total width of the ledge, however, is not yet developed. The depth from the surface, in a vertical line to the ledge, is now 100 ft. Good ore is shown to the end of the tunnel; in fact it has steadily improved since work began.

PANAMINT CONS. MINING COMPANY are pushing ahead with their usual vigor, with very gratifying results. Their mines are still continuing to improve as they are developed. The company have purchased a mill site, and from present indications they will soon need a mill.

MARIPOSA.

HITE COVE.—*Mariposa Gazette*, May 29: From our worthy district attorney, Campbell, who has just returned from a visit to this mining locality, we gather many interesting particulars concerning it. It is situated on the South Fork of the Merced river, about twenty miles north of this place and sixteen from Yosemite. Mr. Hite located the mine in 1861 or 1862, and ran a tunnel into the mountain 1400 feet before striking the vein. Since that time it has been extended fully 3000 feet more, and has branches running in various directions. Mr. Campbell tells us that it is as well improved, and worked to a good advantage as any mine in the State. Mr. Hite has erected at a convenient distance a twenty stamp mill, run by water power, a good hotel, store and other buildings, and has a garden comprising two acres, in the highest state of cultivation, which produces every kind of vegetables. Water fountains play in every direction, and the whole scene is one of comfort and beauty. Great inconvenience has heretofore been experienced for the want of a good road from the top of the mountain, but that want is no longer felt, a first class one having just been completed to the head of the water ditch. The money employed in making these improvements has been all taken from this mine. Mr. Campbell is of opinion that no one can examine the works and improvements here without pronouncing Mr. Hite a man of extraordinary sense, as his head directed all. Contiguous to the Hite Cove mine are several others, which will pay well, when properly opened, viz: the Allen and Mooney mine, the Gibbs, the Georgia Point, and the Reynolds' Cove mine. This latter is an extension of the Hite Cove, just on the opposite side of the mountain. A tunnel is being vigorously pushed in toward the vein, and when reached big results are expected. Mariposa county, we again assert, is the richest in the State for mineral wealth, and the day will yet dawn (and in the not distant future) when this wealth will be developed. Whenever the Mariposa land and mining company shall determine to introduce water upon their possessions from the south fork of the Merced, a rush will be made in this direction that will remind people of the stirring times of '49 and '50.

FELICIANA MINE.—This mine is located twelve miles north-east of the town of Mariposa, near the village of Colorado. It has all the improvements of a first-class mine, consisting of a ten stamp mill, run by a thirty-horse power engine. It has an abundance of water and timber near it. A tunnel has been run, striking the vein 300 feet from the surface. It also has a shaft striking the vein at a depth of 300 feet. The width of this vein is five feet, and it has paid as high as \$300 per ton.

NEVADA.

EMPIRE MINE.—*Gross Valley Union*, June 2: Yesterday was retorting day at the Empire mine, and the product was \$26,000 for a run of twenty-three days. The old mine seems to be rejuvenating, and ready to enter upon a new and vigorous career. The increase has been regular for a number of months, and the above result is the highest figure attained for a month's run in several years. We are informed by David Watt, Esq., Superintendent, that the general underground appearance of the mine is quite encouraging. The tenth, eleventh and twelfth levels, the lowest, are all looking and yielding well. The lead has changed its former characteristics, as it occasionally showed pockets of remarkable richness, with a good deal of low grade ore; at the present time it furnishes no specimen rock whatever, gold seldom being seen in it, but pays well and with remarkable regularity. The working force at the present time, above and below ground, is 110 men.

NEW HOISTING WORKS.—The Omaha works have determined to erect steam hoisting works

upon their mine immediately, and to this end have purchased the engines, boilers and hoisting gear of the Enterprise gravel mine, at Buena Vista elide. Zeph Mansau has taken the contract for removing and re-erecting the machinery, and have it in working order in thirty days. The Omaha has been sufficiently developed to warrant the adoption of stronger and more permanent machinery than they have been using, and with their new power will be able to handle all the water, of which they have a considerable quantity, and to continue their main shaft, and open out the drifts, for several years to come. The mine is looking well throughout, and the dump pile continues to increase in fine rock, rich in sulphurets and free gold.

KENTUCKY MINE.—Our reporter paid a visit recently to the Kentucky mine and found it clear of water. The water was exhausted on Thursday last and men are now employed in fixing up the shaft and getting the mine ready for actual work. A six-inch pump is employed to keep the mine clear of water, but it has to be kept going at a moderate rate of speed to keep it in fork. A force of six or eight men are all that are now employed, but this will be increased shortly. The shaft is down 200 ft. A tub is used to do the hoisting with. A five stamp mill is erected close by, so that the Kentucky will do its own crushing. The prospects that this will be a dividend paying mine are good, and as it is in good hands we think it will soon prove itself to be such.

THE OCEOLA MINE.—We continue to hear rumors that this old mine, situated near Rough and Ready, is likely soon to be started up. The Oseola was at one time a mine of considerable repute, as some very rich rock was taken from it. A twenty-four stamp mill was also erected by the company; but they made the mistake of not getting depth upon the mine, and depended upon taking rock from a tunnel above the water line, much of which proved poor, and besides a difficulty was experienced in amalgamating the gold, which the experience and improvements of later years would now remedy.

YUBA MINE.—*Foothill Tidings*, May 20: Superintendent F. A. S. Jones passed through town on Thursday, and from him we learn that the mine is opening up finely. Both ledges are large and well defined, and the quartz coming out shows well in free gold and is rich in those promising adjuncts, galea sulphurets. The mill was started on Wednesday, and he says the plates look well. The Yuba, which it will be remembered is situated on the South Yuba river, above Washington, is undoubtedly a good mine.

RICH gravel and very extensive is the claim of the Manzsnits company, above Nevada. They have about 100 acres of ground that is thought to be as rich as that worked last year, which paid over \$35,000 to the acre. The earth or dirt of this land to the average depth of 130 feet is washed away by two hydraulic monitors, carrying 1300 inches of water under an immense pressure, and the gold saved in sluices and by all the various modern appliances below. About 50 men are employed during the mining season, which this year will be shorter than usual, though on account of the improvement in the channel the clean-up is expected to be much larger than heretofore.

The Pittsburg mine is looking splendid, and the crushing now at the mill promises to be the best they have ever had.

MINING AT SEBASTOPOL.—*San Juan Times*, May 29: The American mining company, at Sebastopol, commenced sinking a shaft into their new tunnel under construction on Tuesday of last week. They have put an additional number of men at work with a view of completing their tunnel and works in the shortest space of time possible. They anticipate washing through their new tunnel before the first day of May next. In the mean time they will continue to wash off top ground as usual through their old tunnels until the new one is completed. The top ground pays well and gives indications that the bottom ground will pay immensely.

NAPA.

MINING ITEMS.—*Calistoga Free Press*, May 29: The Kentuck mine is looking better and has a brighter prospect to-day than ever before. A large force of men is kept constantly at work running tunnels and sinking shafts. Thos. Cross is superintendent. Dickenson and Michael, of St. Helena, are now handling chrome iron from their mine and shipping it direct to Baltimore, Md., per ocean steamer, as ballast. They have some 5,000 tons on the dump, and 1,000 in St. Helena. Mr. Burke, superintendent of the Calistoga silver mine, informs us that they have made another rich strike in one of the tunnels. The ore being taken out now is about half and half, gold and silver. The last bar produced contained more gold than silver, which is good for the company. J. H. Parks has presented us with a splendid specimen of copper ore, taken from a claim about one mile north of the Mountain mill house, 10 miles from this place. The parties owning the mine are J. H. Parks, Dr. W. M. Michel, Matt Vann and Calvin Griffith. They have run one tunnel in the north side about sixty feet, and have commenced two other tunnels. The specimen we received is a very rich one, assaying, we believe, \$104 to the ton. The California borax company shipped 100 and the American mine 20 fasks of quicksilver through Calistoga in the week ending May 21. The Geyser Peak company are running a tunnel on one of their claims on Geyser peak. At a distance of 70 feet below the surface, a ledge was struck last

week hearing good looking silver ore. Superintendent Powning informs us that he is still at work on the Rocky Bar tunnel, Inyo district, but that the ledge is not yet reached. S. Foster, president of the Star company, has given us the results of milling three hundred pounds of ore from the Wandering Jew claim, Inyo district. Huhn and Luckhardt, of San Francisco, first made assays of the rock, which showed \$5.65 of silver and \$55.25 of gold per ton, and then milled the ore, getting at the rate of \$51.67 per ton. We have seen the small gold brick that came from this ore. The tunnel is now in 80 feet and is still running in the gold bearing rock that was struck several months ago.

PLACER.

STUCK IT.—*Placer Argus*, May 29: Mr. W. J. Meyer has struck very rich rock in the claim known as the Grass Valley and Panamint mine, situated between Gold Hill and Auburn, on Auburn ravine. He says it will pay \$60 per ton, but his wife says \$5,000.

BIO ENTERPRISE.—The *Placer Herald* gives a lengthy account of the operations of the Auburn gravel mining and ditch company, the publication of which we will defer until our next issue.

SONOMA.

LOCAL ITEMS.—*Russian River Flag*, May 27: The Geyser mine shipped 23 fasks of quicksilver Monday last. Owing to the low price of quicksilver, the Rattlesnake furnace will remain shut down for the present.

SAN BENITO.

COAL AND CINNABAR.—*San Benito Advance*, May 29: A day or two since Mr. J. A. Owens covered our table with rocky samples of coal and cinnabar which he found in Quien Sabe valley. The croppings of coal are from a ledge Herland and himself discovered in the foothills of the Mt. Diablo range about a mile from Mr. Owens' camp. The sample before us is the best we have seen in this county. We learn that its merits have been satisfactorily tested at Walberg's blacksmith shop. If as represented it will prove a valuable acquisition to this county. Messrs. Owens and Harland have also discovered several chimneys and a well defined ledge of cinnabar on the hills near Denverport's ranch about a mile west of Stanton's place.

NEW MINES.—*Hollister Enterprise*, May 29: The mineral wealth of San Benito county has just commenced to develop itself. The success attending the development of the Stanton mines in the Coast Range, a few miles west of Hollister, has stimulated prospecting in that direction. J. A. Owens and some other parties have lately discovered what promises to be an immense deposit of cinnabar on the slope of Shelly peak, a mile or so west of the Stanton mines. Large quantities of decomposed metal are found on the surface of the ground, and in spots where the finders have sunk a few inches they found unmistakable evidence of the existence of the pure metal. There is now scarcely any room to doubt that that section of the mountains is immensely rich in quicksilver. It promises to be the second New Almaden of the State.

TUOLUMNE.

RICH.—*Union Democrat*, May 29: Rock paying from \$100 to \$150 a ton is being taken out at the Sonlsby mine in great quantities.

TRINITY.

ANOTHER GOOD CLEAN-UP.—*Trinity Journal*, May 29: The W. D. & H. M. Co. cleaned up last week in the Ward mine on Oregon Gulch mountain, taking out \$2,700 for a run of about 100 hours. With steady water the Ward mine is good for \$500 per day, and can be worked at as little expense as any gravel mine in the State. Water having given out, work has been suspended for this season.

BONNEN.—J. C. Akers has bonded two-thirds of the Washington quicksilver mine, in Cinnabar district, to Jas. Johnson, of San Francisco, for \$4,000. John R. Stoddard has bonded the remaining one-third of the same mine to the same party for \$3,000. The coin is to be forthcoming December 1st.

Nevada.

WASHOE DISTRICT.

OPHR.—*Gold Hill News*, May 27: Daily yield, 150 tons of ore. This ore is mostly taken from the stopes on the 1465 ft. level. The character of the ore is good, and the yield amply sufficient to keep three mills steadily running. On the 1700 ft. level, east cross-cut Nos. 3, 4, and 5 are being pushed forward with all energy possible, to reach and prospect the ore vein on that level. The stone work of the foundation for the new incline machinery is about completed.

SIERRA NEVADA.—Sinking the new shaft is making rapid headway, the rock penetrated being of a much finer character than for some time past. There is no longer water to interfere, the shaft having apparently passed entirely through the vein of water encountered near the surface.

CONSOLIDATED VIRGINIA.—Daily yield, 600 tons of ore. The yield of ore has been considerably increased in order to create a larger reserve in the dump, the crushing capacity of the mills being no greater than for some time past. The mine is looking splendidly on all the levels, affording no new or important features at any point. The mills are running steadily, and its future prospects bright and flattering. The extension of the joint main east drift on the 1400 ft. level to the eastward, the face still in ore, furnishes another proof of the great width of this ore body and its almost incalculable

the value. Everything in and about the mine looking well.

Gouln & Cuatr.—The north drift on the 700-ft level to connect with the Best & Belcher, is making good progress, the rock in the face being still hard but blasting well. Preparations for the commencement of several cross-cuts on the 1700-ft level are being rapidly completed.

BOLLION.—This air on the 1700-ft level of the imperial shaft has greatly improved during the past week, so that the main north drift is being again extended northward, following the west wall of the ledge, and occasionally cutting benches of quartz and ore of a promising character. The east cross-cut from this drift is ore, and the development of paying bodies of ore seem no longer doubtful.

LARRY BRYAN.—The west and south drifts on the 330-ft level are being pushed steadily ahead through a very promising character of bluish-white quartz and low-grade ore.

COSMOPOLITAN.—Ore extraction from the topes, above the tunnel level, is going ahead at a lively rate as usual, about twenty-five tons being the daily yield, which keeps the Hope mill running steadily to its full capacity. Ore of superior richness has been met with during the past week in the northern topes.

CROWN POINT.—Daily yield, 550 tons of ore. There is no material change to report of the re-producing sections of the mine. No new developments to report on the 1600-ft level. Everything in and about the mine working finely.

CALIFORNIA.—Cross-cut No. 5, on the 1500-ft level, has penetrated during the week a body of richer ore than any that has ever been found in that portion of the mine. Cross-cuts Nos. 3 and 4 have also each cut into a richer character of ore than has been encountered for some time past. The face of cross-cut No. 2 east is showing a decided improvement, with evident indications of again cutting into rich pay ore. The point drift on the 1400-ft level is still continued, without yet having reached the east wall of the ledge. A winze has been started from this drift to connect with an up-ramp from the 1500-ft level. The winze is down eighteen ft, and the raise to meet it is up sixty-six ft, both being in good ore. The winze from cross-cut No. 3 on this level will be connected to-day or to-morrow with the 1500-ft level, having passed the entire distance between the two levels through fine ore. The O & C shaft is down 197 ft, in good sinking ground. Laying the foundations for the heavy hoisting and pumping machinery is making rapid progress, the stone work being nearly completed, ready for the reception of the bed-sills. Grading for the new mill is fast approaching completion.

CHOLLAS-POTOSI.—Daily yield, 75 tons of ore, the assay value of which is \$30 per ton. This ore is taken from the old upper workings, and cannot be relied on for a steady and permanent yield. Sinking the main incline is making steady progress. Driving the main south drift on the 1150-ft level is making good progress, the face still in porphyry.

FLORENCE.—The drift west on the ledge, at the 400-ft level is now in 40 ft. Stringers of quartz are beginning to appear, and the formation looks much better and more favorable than at the 300-ft level.

AMAZON.—The cross-cut at the 100-ft station is now in a distance of 40 ft, the face in ledge material of a very favorable character.

JULIA.—Sinking the main shaft is making splendid progress, the Burleigh drills at the bottom doing fine execution. It is now down 350 ft below the 1000-ft level. The flow of water is slight and does not at all impede the progress of the work.

BELCHER.—The main incline is down 34 ft below the 1600-ft station, the bottom still in hard blasting ground. The ore breasts are yielding well. Daily yield, 500 tons of ore. The air shaft is completed to the 1100-ft level. No change of value in any other portion of the mine. Everything working finely.

IMPERIAL-EMPIRE.—Sinking the main incline is making steady and favorable progress. Driving the main south drift on the 2000-ft level is also making rapid headway.

CALEDONIA.—Sinking the main incline at the old works is making fine headway. Sinking the new shaft is considerably retarded by the strong flow of water at the bottom.

ETAOPEA.—The ledge is looking splendidly, and gives high assays, but owing to bad air in the cross-cut east from the winze, work at that point is again suspended.

BALTIMORE AND AMERICAN FLAT.—The cross-cut on the 750-ft level continue to show a favorable improvement in the character of the ledge formation, and strong hopes are entertained that the 850-ft level will develop a fine paying mine.

SUTRO.—The rock in the face of the main drift is still gradually growing softer as the ledge is approached. The indications are excellent for finding ore on this level and considerable expectations are centered on the results. The flow of water is still light.

BUCKEYE.—The prospect for finding ore in the north drift on the 450-ft level is quite favorable.

SILVER HILL.—Everything in and about the mine is working finely. There is no change to note of either the second or third levels, except an improvement in the character of the ore in the north drift at the second station level.

ORIGINAL GOLD HILL.—Both cross-cuts in the south drift at the 340-ft level are in fair grade ore, and a large body of it seems to be opening out. The face of the north drift continues in good looking vein matter.

BEST AND BELCHER.—The Burleigh drills are making good progress in the south drift from the bottom of the winze on the 1700-ft level. No change in the character of the rock in the face of the drift.

SEASOAKEN GOLD HILL.—Cross-cutting actively at the 400-ft level, in good milling ore. A car track is being laid in the main drift, and the guides for the osse in the shaft are nearly finished.

NEVADA.—The stringers of quartz coming in at the face of the cross-cut are growing larger and more numerous, and the vein matter generally is softer than was met with last week.

MEXICAN.—Sinking the winzes in the north drift on the 1465-ft level is making fair progress, with some very favorable indications of yet finding a paying body of ore.

CORNUCOPIA DISTRICT.

MINING ITEMS.—Virginia Enterprise, June 1: Reports from the mines in Cornucopia during the present week have been meager. Work upon the Leopard is progressing as usual, but owing to the scarcity of timbers, in consequence of bad roads, the company has been contending with obstacles which, happily, are now removed. Last accounts report the arrival of timbers, powder and quicksilver, which will enable the miners to prosecute work in any part of the mine, and also furnish the mill with necessary material for working to its full capacity. The stage has brought down to Elko each trip two bars of bullion, averaging \$1,800 each, aggregating for the week six bars, valued at \$10,800.

REVELLE DISTRICT.

GOLD MINE.—The letter of the 24th of May gives the following information: The bullion receipts for May will approximate \$70,000. The south drift from the lower tunnel is yielding finely, the ore being of very high grade and the vein fully five feet in thickness. The drift is in 42 ft. The upper south drift is yielding large quantities of ore. Nine tons of first-class ore is being extracted daily.

EUREKA DISTRICT.

EUREKA CONSOLIDATED.—The weekly letter of the 29th says: Drifting has been commenced on the 8th level, Lewton shaft. The face of the 5th level drift looks favorable for striking ore. The ore body on the 6th level continues to improve as the drift is advanced. It is opening out very large. The main drift, 7th level, is in 527 ft, face in hard blue limestone. The prospecting drifts continue to develop good signs as they are advanced. The Windsail shaft ore body is holding out strong, and the ore body in the Champion ground is improving in quantity and quality.

ELY DISTRICT.

STRIKE.—Pioche Journal, May 23: We hear of the strike of a good ledge of milling ore about two miles west of town, in regard to which those who have been on the ground indulge in the highest expectations. This ledge is 18 inches thick, perpendicular and runs north and south. The ledge is known as the Victoria, and Wes Williams is one of the principal owners. Some of the leading mining men in Pioche have examined the ground and express good opinions of its prospective value.

Colorado.

GEORGETOWN BOLLION SHIPMENTS.—Georgetown Miner, May 29: The Stewart silver reducing company shipped for the week ending May 28, \$9,468. Judd & Crosby's reduction works shipped during same time \$4,779.

DOUGLAS TUNNEL.—We are glad to say that Mr. Goetzl's great enterprise for developing the hidden wealth of Douglas mountain bids fair to accomplish all that has been most sanguinely hoped for. At 600 ft the fourth lode or "mother vein," has been cut into, but the workmen are not yet through it. It carries mineral of a very high grade.

OWNERS OF LOW GRADE MINES carrying a high per cent. of galena, are now anxiously inquiring about the probabilities of the smelting works in the valley starting up this season. Fully a score of large mines are now lying idle, waiting the proposed market for their ores. The output of this district will increase 35 per cent. yearly when we can load this class of mineral on cars in Georgetown for Golden or Denver. We are assured that both establishments will soon enter the market, and the extension of the C. C. to the prospect of Georgetown is now more promising than it has been.

Idaho.

WAGONTOWN MINES.—Owyhee Avalanche: We continue to receive the most favorable reports from the newly discovered gold mines near Wagontown, which are two hours' walk or more from Silver City. Mr. Mays, an old prospector in this camp, has been down there the past two weeks, and he confirms the general opinion in respect to the abundance of rich ore in that vicinity. Mr. M. was working some valuable claims near town a month ago, but abandoned them for what he regards as a more productive field. All that is needed he says to work the new mines successfully is capital, which, with the requisite facilities, will, he predicts, accomplish wonders in that locality.

GOLDEN CHARLOT.—A letter of the 29th says: The new discovery is now opened by a drift over 50 ft in length, and the faces continue in ore. The drifts both north and south, and on the back of the level, show a continuous body of high grade ore. For this same body cross-cuts are being run from both the first and third levels. The ore from the winze from the ninth and tenth Minnesota continues very fine. All the other drifts continue in about the same kind of ground and ore as when last reported.

WAR EAGLE.—A dispatch of the 1st says: The 7th level is opening out fine.

Oregon.

CINNABAR.—Oregon Sentinel, May 29: We have within three miles of Jacksonville the largest cinabar ledge that has yet been discovered and which is now being thoroughly prospected. A cross-cut having been run eight feet in depth and ten feet wide, shows the ledge to be 60 feet wide from ceiling to casing. They have sunk a shaft in the cross-cut to the depth of 35 feet, and the ore looks very fair all the way down, and seems to be of a better quality the farther down they go on the ledge. Messrs. John Bilger, E. D. Foudray, West Manning, T. McKeuzie, M. Oston, E. D. Watson, J. H. Peun, J. B. Coates and H. K. Hanna, are the names of the gentlemen who compose the company. They are pushing the work vigorously forward in the shaft, and they expect in a few days to strike a very rich vein of ore, as the present appearance of the rock is very encouraging. We wish the gentlemen success in their undertaking, and trust they will realize a handsome profit for their investment, as certainly the energy and enterprise of these gentlemen in developing this lead is worthy of a flattering reward.

OREGON PLACED MINES.—Cor. Sutter Banner, May 29: A correspondent writing from Auburn, Baker county, Oregon, under date of May 10th, gives us a few items concerning the mining claims in that vicinity. He says: "The oft reported richness of the mines here are not over-rated; last week a nugget worth \$200 was picked up in one of the claims, and most of the claims will yield \$10 to the man."

He also says N. C. Haskell, formerly of the Banner, and Daniel Best are both there and in good health and spirits; the latter began piping in one of the gulches on the 3d inst., and is now washing out about 1,500 square yards of earth per day with a good clean-up in anticipation. He says the weather is very cold; from the 5th to the 8th inst. it snowed and hailed so hard that but little work could be done. He writes encouragingly of the prospects, and has no desire to return to his old familiar haunts.

MINING ITEMS.—Weekly Oregonian, May 29: They are passing around the hat for contributions to work up rock of the famous Yank ledge in Jackson county.

It is reported that the Eagle mining company has sold its black claim in Coos county. The terms are not made public as yet.

The big mining ditch at Eldorado, Baker county, owned by Carter & Packwood, is now furnishing 400 inches of water, and good results from the mine in that vicinity are anticipated.

MARSHALL & DEALEY, placer miners, Olive creek, Grant county, picked up from their "ground sluice" one day week before last, the sum of \$3,000 in nuggets, weighing all the way from half an ounce to six ounces.

POWEAS & CO., of Rye Valley, Baker county, made a clean-up from a short run in their placer claims, and had the proceeds run into a bar at the assay office in Baker City on Monday of last week. The bar was worth \$2,500.

Utah.

NEW TRAMWAY AT THE LITTLE COTTONWOOD CANON.—Cor. Salt Lake Tribune May 24: During the past week several San Francisco and New York capitalists have been here, discussing the practicability of building a Halliday patent wire tramway from here to the end of the railroad. The distance is less than six miles, and the cost is estimated at from \$250,000 to \$300,000. It would be set up on stations at least 20 ft above the ground, and would not be bothered with snow in the least. There is no doubt but that this would be a big paying investment, as all the up freight, passengers, etc., would pass over the line, and there would be at present from 250 to 400 tons of ore daily to go down, which amount would be very materially increased if transportation was reduced. As this camp contains hundreds of thousands of tons of low grade ore, which will not quite pay for working at the present rates of freight, this class of ore with cheap transportation would leave a nice margin. It now costs about 18 per cent. for sacking and shipping. A tramway company could make a nice thing at \$4, as the ore could be taken in bulk, and the expense of sacking dispensed with. It is thought this enterprise will be put through this season, and if so, it will be a great thing for this camp, and cannot fail to be a paying investment.

BULLION REFINING.—Dr. Linderman, Director of Mints, expects to be able by the 15th of July to refine and part all bullion produced in the country, instead of having one-half at least sent abroad for that purpose as has been the case heretofore, on account of insufficient refining capacities in the United States. The new refinery at San Francisco is thought will be ready by that time. The refining capacity of the United States assay office, in New York, will be trebled, and that of the Philadelphia mint considerably enlarged. The Director of Mints will leave New York about the 9th for this coast. On his way out he will stop at Cincinnati, Indianapolis, St. Louis, Kansas City and Denver, and on his return at Omaha and Chicago, for the purpose of determining what point in the West is the best located for the proposed new mint.

Another \$1,500,000 of the Consolidated Virginia mine bullion has been sold to the Government, to be paid for in gold coin from the office of the Sub-Treasurer in San Francisco.

Hints on the Washoe Process.

(Continued from last week.)

The Treatment of the Pulp in the Pans, Continued.

When each charge is withdrawn, it is well to wash out the pans with water, so as to get all the quicksilver possible out of the pan. There will still remain from thirty to sixty pounds in a flat bottomed pan (though this form is on other accounts to be preferred) under "and around the dies or the lower grinding surface; and there will be, also, more or less amalgam sticking in various places on the sides of the pan, the muller, etc. Charge the pan with the muller raised, and turn live steam directly into the pulp. This method is preferred because in this way the pan is heated much more rapidly than by a jacket, or double sides and bottom, filled with the exhaust steam; and little work can be done by the pan until the charge is heated. The pulp should also be heated, almost to boiling. The consistency of the pulp when the quicksilver is put in should be as thick as possible consistently with a good circulation in all parts of the pan; but, inasmuch as the pulp will be ground faster when thin, it is best to have it thin at first. To secure both objects, the pulp may be diluted to such a degree that, after grinding two and a half hours, it will have thickened to the proper consistency for recovering the quicksilver. If this condition is fulfilled, the quicksilver charged into the pan will, after its speedy division into small globules, occasioned by the grinding and heat, be diffused through the whole mass. A sample of the pulp taken out on a thin wooden spatula should show particles of uniformly disseminated quicksilver. Some of the globules will be microscopic; but from an ounce of the pulp, washed in a hour, a good sized globule of quicksilver may be collected by rubbing, etc. The pulp, if of proper consistency, will have a good motion, yet be thick enough to carry the quicksilver in suspension just to the surface, as the current rises from under the muller on the outside of the pan. On the other hand, the large globules of quicksilver will be able to gradually sink through the pulp. Thus the quicksilver describes a course distinctly its own, and a more intimate contact is attained.

If selt is used, it should be introduced as soon as the pan is charged. Sulfate of copper, if used, should be added as soon as the pan is heated up, which ought to take place in fifteen minutes. Then the steam should be shut off and the muller lowered, and grinding commences. The reason for not lowering the muller at the start is to save power, since the pan will grind but poorly, and that with difficulty, in the cold pulp. If the pan has a cover on it, (as all pans should have,) probably there will be no necessity for using the steam again till the charge is drawn and a new one put in, since sufficient heat will probably be retained to render amalgamation effectual.

It may be assumed as a fair average that the charge is run five hours. All the chemicals used, except those for saving quicksilver, are put in the pan at different times, and, after the last one is put in, there should be at least twenty minutes before the quicksilver is charged. I prefer to put in the quicksilver in the middle of the period, i. e., two and a half hours before drawing the charge, and at the rate of 200 pounds of quicksilver per 2,000 pounds of ore, or a larger proportion of quicksilver if required by the richness of the ore. Three-quarters of an hour before discharging, the muller is raised, since, if the pan is in good order, the charge should be by this time thoroughly ground, and raising the muller avoids further cutting up of the quicksilver by the grinding. At the time of raising the muller, the chemicals used for saving quicksilver may be added. Fifteen minutes before drawing the charge sufficient water is added to thin the pulp thoroughly. This prepares the charge to flow readily out of the pan, and also stirs up any pulp that may be moving sluggishly.

The range of these remarks being merely mechanical, the subject of chemicals (mainly salt and sulphate of copper) in pans will not be here discussed. Suffice it to say at present, that my practice and numerous experiments have disposed me strongly in favor of using chemicals, and using them largely. When only a low percentage is expected, and from a docile ore, there is often no need of any chemicals at all, though even then a judicious use of suitable re-agents will save some of the quicksilver. The more refractory the ore, the greater necessity for chemicals, and for high heating of the pans. From ordinary and docile ores eighty per cent. of the assay can in some cases be obtained readily, without use of chemicals, by enforcing all the small mechanical details, such as those I have referred to, and by keeping the quicksilver in perfect order. The additional percentage obtained, running up to ninety-five per cent. and over, which I myself have frequently obtained, on gold and silver ores, is only to be gained by the use of chemicals.

The most important point in the process is to keep the quicksilver always bright, clean, active, and in good order. In working an ore that fouls the quicksilver, if it is not practicable to keep the quicksilver clean in the pan, it should be at least put in perfect order before it is again used for another charge. In such cases it is important to keep the pan as free from quicksilver as possible during the first part of the process. For cleaning quicksilver, sodium amalgam, caustic potash, dilute acids, cyanide of potassium, etc., are used. Even in docile ores it is well to keep a cleaning mixture on the quicksilver under the strainers.

(To be Continued.)

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Fifteenth Lecture Delivered before the University of California College of Agriculture, on Tuesday, February 9th, by Prof. C. E. BESSEY.

(Reported and Illustrated for the RURAL PRESS.)

Improvement of Varieties.

When we consider plants and animals, we are apt to look upon them as existing as definite, and to a certain extent invariable species; but a critical examination shows them to us as varying with every varying circumstance.

In the ordinary agricultural and horticultural operations we have to deal with about 100 species of plants and sixteen species of animals, not including, of course, the many with which we have indirect relations, as for example the insects which destroy our crops, the vermin which attack our stores and the fungi which rot our wooden houses and barns.

I include only those which we grow voluntarily, and which give us the "products" of our farms and gardens, the trees which afford us lumber and fuel, and the wild shrub from which we gather it may be considerable quantities of berries, are left out. Here, then, we have 116 original species or forms, from which have been derived the animals and plants, bought, grown and sold by the farmer and gardener of to-day. These original forms, furnished by nature to man, were

The Crude Materials

Which he could modify, change and almost rebuild to supply his needs. Scarcely one out of the whole list of food plants but was originally almost inedible, and of the animals we have only to compare the Suffolk hog and the short-horn ox with their lean, lank progenitors, to see what necessity there was for an improvement upon the original wild species. I will select a few of the most prominent from my list. First the plants: The cabbage in its wild state was a leafy, long-stemmed plant, growing no head and furnishing only a small amount of coarse food. Now, under cultivation, that one poor form has developed into five or six species, each of which has again developed further into many varieties. Taking up one of the seed catalogues, I find sixty-nine varieties of the cabbage. They may be translated as follows: [See Figs. 1, 2, 3, 4 and 5.]

1. Sub-species *Acephala*, Kale or Boricole, eight varieties. 2. Sub-species *Bullata*. 3. Sub-species *Capitata*, common cabbage, twenty-eight varieties. 4. Sub-species *Carlo Rapo*, Kohl Rabi, four varieties. 5. Sub-species *Botrytis*, (a) Cauliflower, twelve varieties; (b) Broccoli, eleven varieties.

Each of these types may be considered as a center from which the varieties have diverged, as in the diagram.

Turn now to the apple, supposed by many to be a single species. By referring to Downing's Encyclopedia of Fruits and Flowers, I find that there are in America alone about 1800 varieties, differing enough from one another to be distinguishable. Examine the particulars of the variations and they will be found to relate to shape, size, color, texture and taste of fruit, with equal modifications of bark, stem, branch, twig and leaf and differences in habit, hardness, keeping qualities and time of ripening. Here we have a dozen or more characters, all of which are variable. Now, each variation of these characters may give us a new variety, so that the number of possible distinct varieties is practically limitless, and the number given before as described in Downing may be considered as but the beginning of a long list which is destined to grow larger and larger as long as man shall continue to grow the apple.

The pear, I need but mention to call to your minds what changes have been wrought upon the original wild and almost inedible fruit—to-matoes, potatoes, wheat, oats and maize are all among illustrations. The first, the tomato, has been grown in kitchen gardens for less than half a century, and yet we find in catalogues upwards of fifty varieties, exhibiting differences in fruit, stem, leaf, hardness and time of ripening. In the potato, varieties have run away up into the hundreds. In 1870, I grew in the gardens of the Iowa College of Agriculture upwards of eighty varieties, all of which had characters sufficiently well marked to enable anyone to distinguish one from another. Mr. Grunell, of Clayton, Iowa, has had on his list fully double that number, while Dr. Hexamer, of New Canaan, New York, advertises in his catalogue two hundred varieties, and there is no doubt that if all the kinds grown in different parts of the country could be gathered up and enumerated, the list would be more than doubled.

Let us now inquire what bearing this fact of the variability of species has upon agriculture and horticulture. As man has gone from one country to another he has naturally carried with him the plants and animals which he had been accustomed to have about him in his old home. But many a time, as he moved, the change of climate was so great that the old varieties could not be grown in the new locations. Sometimes the change was from a moist climate to a dry one, as in passing from the Atlantic States to the plains of the Mississippi

valley. Again, it was from a mild climate to one of great severity, as in passing from Europe to the east coast of America; or it was from one soil to another, as was the case in passing from the clays and sands of New England to the alluvial soil of the Mississippi valley.

What has been the Result?

Often after many failures to grow the more tender varieties, hardy ones appeared, so that now but little difficulty is found in growing them. In passing from the protected regions around the great lakes to Iowa and Nebraska many old varieties of apples had to be discarded. The old Rambo, the Rhode Island Greening, the Baldwin, the Bellflower, the Follawalter and many other old standards were found to be tender, and the result was to be seen in the many trees killed down each winter.

It may be said that in Iowa all the orchards first set out were killed because the varieties were too tender—and yet now it produces the finest apples east of the Rocky mountains. Another good illustration may be furnished by maize or Indian corn, which has produced varieties fitted to all the differences of climate

Fig. 1. Acephala.

Fig. 2. Bullata.

found in the United States. The tall, rank-growing sorts are found in the Southern States, where the summers are long enough to ripen the great mass of vegetable matter; but in New England and New York, where the summers are short, the small, eight-rowed, flinty kinds are grown. How is it that throughout all except the most northern of the United States we can grow the peach to perfection?

Look upon the map and note that Persia, the native country of the peach, lies mainly south of the center of the United States. Trace its isotherm of 70 degrees and you will find it to pass through Northern Africa, through Florida, Louisiana, Texas, Northern Mexico and the peninsula of Southern California—and yet from

Fig. 4. Carlo Rapo.

that warm climate the peach has spread, in its hardy varieties, northwestward into Europe and throughout all but the most northern of the United States and I have been informed on good authority that a German horticulturist, near Madison, Wisconsin, has recently grown peach seedlings which prove hardy even in that cold climate. I might go on multiplying instances—but these are perhaps sufficient to show that through its variations a species naturally suited to one climate may become fitted to endure the inclemencies of another.

If these variations of the original occur—and occur so opportunely for man—the questions which interest us are: First, whether varieties

Fig. 3. Capitata.

Fig. 5. Botrytis.

arise independently of man's labors, or, are due to something which he has done and second, if man has anything to do with the production of varieties, what are the causes of such variations, which lie within his control, in other words,

How Can Man Produce Varieties?

Dr. Gray, in the *Naturalist* for February, 1874, puts the first inquiry in this form, "Were the fruits made for man, or did man make the fruits?" and in answer says: "Some fruits were given to man as they are and he has only gathered and consumed them. But these are only minor fruits and such as have lately come within the reach of civilized man—or, are not thought worth his trouble; huckleberries and cranberries, persimmons and paw-paws are examples taken from this country. Whether even such fruits have or have not been under a course of improvement irrespective of man is another question. Others have come to man full flavored, and nearly all that he has done has been to increase their size and abundance, or, extend their season; currants and gooseberries, raspberries and blackberries, chestnuts and above all strawberries, are of this class. But most of the esteemed or important fruits

as well as the grains have not so much been given to man, as made by him. The gift outright was mainly plastic—raw material—time and opportunity." As to this second query—How man may produce varieties—in order that we may answer this, it will be necessary to discuss reproduction, prepotency or power of transmitting qualities, climate, culture and crossing—all of which are more or less under man's control, together with spontaneous varieties or sports and reversion, which come in as disturbing elements, if not understood; but which under skillful manipulation may even be made to aid the grower or breeder. These, then, will be the topics which we will consider in these lectures.

Coast Railroad Items.

The San Francisco Post, in speaking of the departure for Los Angeles of Col. Crawford, Chief Engineer, and Jas. A. Bitchard, Secretary of the Los Angeles and Independence railroad, says: This road is one of the most important enterprises ever projected in this State. Senators Jones and Stewart are determined to carry it through at the earliest day possible, not only for the benefit of their mining interests at Pausmint, but also in the hope of effecting a combination by which a direct rail route may be opened through to Ogden, independent of the Central Pacific. Jay Gould and Senator Jones have been in close consultation recently on the subject, and it is more than likely that something may come of it, as Mr. Gould is particularly anxious to reach the Pacific coast without coming over Stanford's line. The idea proposed is to extend the Los Angeles road from Independence, the present projected terminus, through the southern part of Nevada, striking Pioche and other important mining camps, and tapping the Utah Central railroad at or near Beaver, Southern Utah. Mr. Pritchard says there are vast coal beds at different points on the projected route which would prove a mine of wealth could they be opened up and their treasures brought to market. Mr. Jones will be here in about two weeks, when work on the Los Angeles road will be driven forward in earnest.

The Central Pacific people are preparing to push through the Woodland and Colusa railroad to completion. The crops from Berryessa valley, Napa county, will come over the Winters road, and large freighting facilities will now be needed at South Vallejo. The iron is being laid between Viscaville and the new town of Winters in Yolo county. The grading of the Berryessa wagon road will commence this week. An A 1 Baldwin engine and three coschees have been built for the railroad, which connect by the wagon road with the Redington and California mines.

According to the Nevada county papers, work is progressing rapidly on the Nevada County narrow gauge railroad. The grade is completed from Colfax to the deep cut near the Central Pacific railroad bridge, which crosses Long ravine. There are two gangs of men at work in the cut, and it is expected they will complete it within ten days. The bridge builders are preparing for work on the trestling and bridges across Bear river and Greenhorn. Work on the grade, between Grass Valley and Nevada, will be commenced in a few days.

The survey for the new road from Colfax to Forest Hill, in Placer county, by way of the North Fork of the American and Shit Tail canon, is now being made. Favorable grades are reported, and it is confidently anticipated that the road will be constructed at an early day. With this road all the travel and freighting of Eastern Placer will be done by way of Colfax, instead of through Auburn, as heretofore.

The new time table of the Southern Pacific railroad will be issued in a few days. The change will commence on Sunday—and cars will make six trips daily each way to and from School House station. One early train from Millbrae station will reach the city at 6:45—one noon trip to San Mateo—and a 6 p. m. trip to School House station. The fare will be materially reduced.

The Santa Barbara Press says that about thirty gentlemen, well known for their broad views, sagacity and enterprise, with ample means to carry out the project, held a meeting and resolved upon organizing to construct a railroad from that place eastward to Lyon's station, on the Southern Pacific route, with the intention ultimately to continue it on to Arizona.

The depot building at Caliente, the present terminus of the Southern Pacific, now completed, is about one hundred and seventy feet long by forty feet wide. A large platform is being built at one end as a transfer of heavy freights, such as mining machinery and building.

Work has at last been commenced on the Stockton and Ione railroad. On Monday eighty teams were employed in grading on Souma street, Stockton, and it is the intention of the new managers to push the work forward with dispatch.

Rollins stock for the Vacaville railroad is already on the spot. The new town of Winters is making a handsome beginning. Lots worth \$22,000 are already sold.

One thousand five hundred men are now at work on the Southern Pacific railroad at Tehichipe pass.

The annual meeting of the City railroad company will be held on the 21st of June.

Quicksilver Mining and Its Profits.

The present low price of Quicksilver has caused many who were accustomed to consider \$1.40 or \$1.55 something normal to think that the fall in value consequent on increased production was unremunerative and would probably result in the closing up of some of the newly discovered mines. That these fears have no foundation in fact, and that even a lower price would be remunerative is however the fact, the truth being that Quicksilver mining in proportion to the capital invested in it has yielded enormous profits—profits far out of all proportion to those made in any other pursuit or in any other instance, save perhaps, in some of the wonderful claims on the Comstock or in some of the diamond fields of Brazil.

Prior to 1874 the number of mines were limited to two in Europe and three in America—the total production was concentrated in a few hands, and this indispensable metal brought just what price the combination of mine owners pleased to put on it. That price in this city for 1874 averaged \$1.37 1/2 per pound, or about 87 1/2% higher than the average price for 25 years. That price was, taking into account the value of exports and that consumed on the coast, 50c per pound.

The total quantity produced in the State in 1874 was 34,154 flasks or 2,612,781 pounds, and the difference between the average price for years and the average price last year was as follows:

2,612,781 lbs at \$1.37 1/2 \$ 3,679,404.72

2,612,781 " " 50c 1,306,390.50

Extra Profit of 1874..... \$ 2,272,714.22

This of course, does not represent the whole profit, for the cost of extraction, etc., is not over 26c per pound. The extra profits made during the years 1871, 1872, 1873, and 1874 have been as follows:

1871.

2,438,896 lbs at 90c..... \$ 2,144,507.04

2,438,896 " " 50c..... 1,219,448.00

Extra profit..... \$ 1,195,059.04

1872.

2,318,409 lbs at 80c..... \$ 1,854,727.20

2,318,409 " " 50c..... 1,159,204.00

Extra profits..... \$ 695,523.20

1873.

2,087,900 lbs at 90c..... \$ 2,047,042.00

2,087,900 " " 50c..... 1,043,950.00

Extra profit..... \$ 1,003,092.00

1874.

2,612,781 lbs at 90c..... \$ 2,351,502.90

2,612,781 " " 50c..... 1,306,390.50

Extra profit..... \$ 1,045,112.40

Total in four years..... \$ 5,165,388.46

Divided amongst a comparative few, these are enormous profits in the short space of four years, but they are only part of the real profits, as the figures of gross value of Quicksilver sold and of cost of extraction stand thus:

Total value of Quicksilver..... \$ 9,905,380.96

" cost " 2,459,076.38

Net profit for four years..... \$ 7,436,304.58

This shows that for every dollar expended the owners of the mines have taken in over four dollars, which amount has come out of the pockets of the miner, mine owner, etc., etc., throughout the world. The total product since the mines were first opened have aggregated 683,979 flasks of 76 1/2 pounds each or 62,324,393 pounds, and the total profit made has been as follows:

62,324,393 lbs selling at an average of 50c..... \$ 31,162,196.00

62,324,393 " costing " 20c..... 12,464,878.60

Profit..... \$ 18,697,317.40

No wonder with such profits as these that there should be contests, such as that in which McGarahan is engaged, waged year after year with the expenditure of hundreds of thousands of dollars. The prize to either contestant is a princely fortune and the present holders of the mine could well afford to spend the profits of years when in case of success they had those for an illimitable period open before them.

It is therefore a great mistake to suppose that 65c represents the bed-rock price. At 40c a profit of 54 per cent. nearly would be made, and in the cheapness of this indispensable metal a chance would be afforded for the development of much of the mineral wealth of the coast that is now unworked and has from the high price of Quicksilver been unworkable with profit.—*Journal of Commerce*.

THE INVENTOR'S PARADISE.—"A thousand patents," says Haseltine, Lake & Co's London circular, "are granted every month in the United States for new inventions. This number exceeds the aggregate issue of all the European States, yet the supply does not equal the demand, and the average value of patents is greater in America than in Europe by reason of the vast number of new industrial enterprises and the higher price of manual labor. A hundred thousand dollars is no unusual consideration for a patent right, and some are valued by millions. The annual income from licenses granted on the Blake Sole Sewing Machine is over three hundred thousand dollars—and other patented inventions are equally profitable. Inventors are encouraged by the moderate government fee of thirty-five dollars, which secures an invention for seventeen years without further payment—the right of patents are generally respected by the public, and no National Legislature, with a single exception, has ventured to propose the abolition of a system which at once secures substantial justice to inventors and proves of incalculable advantage to the nation."

The annual meeting of the Sutter Street railroad company will be held on June 14th.

GOOD HEALTH.

Fetid Feet.

Some persons can be "smelled" a mile off, more or less; it is a misfortune, and a source of very great mortification to the refined and sensitive. It may be "born" with some; with others, if not all, it is the result of a diseased condition of the system, or of a neglect of personal cleanliness. There is a peculiar odor emanating from the feet, which is, perhaps, always the result of uncleanness. If daily washings do not remove these odors, a very efficient wash is found in red oxide of lead, one part to twenty-nine parts of the liquor of the sub acetate of lead; the first to be bruised in a porcelain mortar, gradually adding the latter; apply a few drops once a week, oftener in summer.

A specific odor escapes every one, and is peculiar to the individual; the dog knows it, and by it follows his master through any crowd of human beings, and never makes a mistake. A man's odor of smell is not thus acutely developed; still there are persons whose peculiar penetrating odor is readily recognized. This does not come from the "sweat" of the person, as no such odor issues from the hands, but from the arm-pits and other parts kept covered by the clothing, so that the air cannot penetrate; nor is the application of soap and water too frequently allowed. When the "sweat" remains in contact with the skin, it undergoes a chemical change, and it is this which disengages the peculiarly disagreeable odor, as to the feet particularly; thus this chemical formation is a kind of feid fat, which is absorbed into the pores of the leather, and there it is detained with fresh additions daily, for weeks and months, with increasing rancidity, as the smell of any old boot or shoe will demonstrate. Some persons wear stockings without change from the time they are first put on until they are worn full of holes. Very many do not wash their feet oftener than once a month; only a few as often as once a week. To be scrupulously clean, the feet should be washed every night before going to bed, and no stocking, boot, or shoe should be put on a second time, until it has had a whole day's sunning, at least by those who have an ambition to be and feel as sweet and clean as a dew drop on the rose of summer; or put two tablespoonfuls of the compound spirits of ammonia (hartshorn) in a basin of water, and wash the face, hands, arms, arm-pits and feet with it. The skin is left fresh, clean, and sweet; it is perfectly harmless, and costs but little.—*Hall's Journal.*

SALICYLIC ACID—THE NEW DISINFECTANT.—The powers of carbolic acid to arrest fermentation and putrefaction are well known. But its odor is to most persons decidedly offensive, and if taken internally, even in minute doses, it is apt to produce very serious results. According to the recent investigations of Professors Kolbe, Knap and others, salicylic acid possesses the same antiseptic power without the accompanying disadvantages. It is odorless, of a faintly sweet taste, and can be taken internally, even in relatively large doses, without injurious effects. It will, therefore, prove of great value in preserving meats, eggs, fruit, preserves, beverages, medicinal preparations, inks and a great variety of organic matters from mouldiness or putrefaction. One part of the acid is capable of preserving 26,000 parts of water from becoming tainted. Small traces of it prevent wines, malt liquors, etc., from turning sour in cask or bottle.

THE mental condition has far more influence upon the bodily health than is generally supposed. It is no doubt true that ailments of the body cause depressing and morbid conditions of the mind; but it is no less true that sorrowful and disagreeable emotions produce disease in persons who, uninfluenced by them, would be in sound health; or if disease is not produced, the functions are disordered. Not even physicians always consider the importance of this fact. Agreeable emotions set in motion nervous currents which stimulate blood, brain, and every part of the system into healthful activity; while grief, disappointment of feeling and brooding over present sorrows or past mistakes, depress all the vital forces. To be physically well, one must in general be happy. The reverse is not always true; one may be happy and cheerful and yet be a constant sufferer in body.

SUNFLOWERS FOR FEVERS.—Favorable mention continues to be made of the virtue of sunflowers as preventives of bilious fever, chills, fever, etc. A correspondent writing from a place in Alabama, which he says was peculiarly subject to fevers, gives the results of his experience on the premises, and in not a single instance where he planted sunflowers around his negro cabins did their inmates suffer from fevers, while his wife, two children and two house servants all had fevers, he not having planted any of the sunflowers around his dwelling, which, in his opinion, accounted for the difference in the results.

CURE FOR CHILBLAINS.—Glycerine, one ounce; carbolic acid, one-half a dram; mix, and apply night and morning. If the suffering is severe, soak the feet every night in a tea made of white oak bark. The remedy is said to be infallible.

Chloral In Sea-Sickness.

First, no person should take more than twenty grains of chloral, or its equivalent of two teaspoonfuls of the syrup of chloral, in one dose, without the advice of a physician. Secondly, the action of the drug will be much expedited by diluting the dose largely, say with half a tumbler of water. Thirdly, the remedy should be taken before the vessel is in motion, but not until every arrangement has been made which will insure the patient against being disturbed or roused during the passage. Fourthly, the patient should lie down, and—weather permitting—remain on deck. Fifthly, although chloral taken in the dose indicated will generally induce sleep, the patient may pass into a semi-conscious, dreamy state, quite as favorable for the purpose under consideration. The drug is, however, cumulative in its action, and must not, therefore, on a short passage, be repeated. More than two years ago I ventured to prevent a lady going to Ostend from taking a fourth repetition of what I ascertained to be a twenty-grain dose of chloral, which she had been told by a friend must be continued at short intervals till she slept. On arrival at our destination she was taken off the vessel in a perfectly unconscious state. In long voyages, however, as to America, I have advised with success two doses of twenty grains, taken at intervals of eight to ten hours, and afterward five-grain doses twice daily till the patient becomes accustomed to the motion of the vessel. Persons always have and always will use remedies without medical advice, and accidents will continue to occasionally result from such practices. It is the recollection of the many such misadventures which have already attended the use of chloral taken unadvisedly for the relief of pain, that induces me to think these precautions for its use in sea-sickness worthy of attention.—*Exchange.*

REMEDY FOR LOCKJAW.—Smoke the wound or bruise with the smoke of wool. Twenty minutes in the smoke of wool will take the pain out of the worst wound, and repeated once or twice, will allay the worst case of inflammation arising from a wound.

SORELET FEVER in a very dangerous form, is prevailing in Sacramento and vicinity, and has proved fatal in a number of cases. In some families two and three children have died.

Useful Information.

TO FORM PERFECT SQUARES.—Squares can be tested with the dividers by drawing two circles, one within the other, from the same center, of sixteen and twelve inches diameter respectively; then set the dividers to ten inches, insert one point in any part of the outer circle, and mark the point exactly where a circle (drawn with the dividers in this position) would intersect the inner circle; now draw a straight line through the center of the circles and through the point marked in the inner circle; and through the outer one, another line starting from the point where the dividers were inserted in the outer circle through the center of the circles, until the outer circle is reached. If this is done exactly, the points where those lines intersect the outer circle will form the corners of a perfect square whose side is 11.3137 inches. If the square is correct, it will fit the square thus formed and also the lines in the center, which divide the circle into four equal parts, and the angles must be ninety degrees. This is based on the rule for finding the hypotenuse of a right angled triangle, thus 6 square=36 and 8 square=64, sum 100, the square root of which is ten. This is sometimes called the six, eight and ten rule for squaring buildings.—*Ex.*

TO PRESERVE POSTS.—The *American Chemist* says that a Western farmer discovered many years ago that wood could be made to last longer than iron in the ground. Time and weather, he says, seems to have no effect on it. The posts can be prepared for less than two cents apiece. This is the recipe: Take boiled linseed oil and stir into it pulverized charcoal to the consistency of paint. Put a coat of this over the timber, and, he adds, there is not a man who will live to see it rot.

The expensive part of the Daniells battery is the copper plate, the cost of which can be reduced two-thirds in the following manner: Procure sheets of the ordinary sheet tin of commerce, brighten, and plunge into a very weak copper-plating solution, in connection with a voltaic battery of a very low quantity. In fifteen minutes a tenacious film of copper will have been deposited on the tin and the plate can then be bent into shape and used in the ordinary manner.

According to Botger, nickel is better adapted than any other metal for galvanizing iron, and it resists the action of oxidation much better than gold. The latter metal is very porous when it is in a thin layer; nickel, on the contrary, forms a thoroughly impermeable coating.

FRENCH papers speak of a newly invented texture, a kind of cloth manufactured of the down of chickens, ducks, etc. It is waterproof, and may be dyed in all the different shades. The experiments have met with great success.

ALCOHOL—CURIOUS CHANCE OF MEANING.—Dr. Richardson in a recent lecture gives some information, says the *London Medical Record*, on this much used word. He says that the first employment of the English word alcohol is obscurely recorded. Bartholomew Parr, one of the most learned of scientific classics, taking the usual derivation of the word from the Arabic Al ka-hol, a subtle essence, says it was originally employed to designate an impalpable powder, used by the Eastern women to tinge the hair and margins of the eyelids. As this powder, viz., an ore of lead, was impalpable, the same name was given to other subtle powders, and then to spirit of wine exalted to its highest purity and perfection. The earliest systematic and truly scientific use of the term that Dr. Richardson could discover is in Nicholas Lemert's "Course of Chemistry," published in 1698. Then the word is used as a verb, "to alcoholize," and the definition of this is said to be "to reduce to alcohol, as when a mixture is beaten into an impalpable powder." The word, says Lemert, is also used to express a very fine spirit, "thus the spirit of wine well rectified is called the alcohol of wine."

BALLOONING.—The following practical hints on ballooning are published by Donaldson the aeronaut, in a little paper edited by him and named the *Aerial*. The lifting strain of a balloon is principally upon the net. If a balloon will stand inflation, it is safe in mid-air. In winter, the atmosphere is warmer one mile above the clouds than it is at the earth's surface. The weight of a balloon to carry one man, including net and basket, should not exceed 80 pounds. A cotton balloon will last for about sixty ascensions. A balloon thirty feet in diameter undergoes a strain of 1½ pounds to the square foot of surface. Gas which at the earth fills the bag only half full, will, at an elevation of 3¼ miles, expand so as to fill it completely. One thousand feet of coal gas will raise 38 pounds. Gas which gives a poor light is the best for aerostatics. Kites can be used to steer by sending them up or lowering them into currents of air traveling in different directions from that in which the balloon is sailing.

WATERPROOF PAPER.—The French papers speak of a method of rendering paper extremely hard, and tenacious by subjecting the pulp to the action of chloride of zinc. After it has been treated with the chloride it is submitted to a strong pressure, thereafter becoming as hard as wood and as tough as leather. The hardness varies according to the strength of the metallic solution. The material thus produced can be easily colored. It may be employed in covering floors with advantage, and may be made to replace leather in the manufacture of course shoes, and is a good material for whip-handles, the mounting of saws, for buttons, combs and other articles of various descriptions. An excellent use of it is in large sheets for roofing. Paper already manufactured acquires the same consistency when plunged, unsized, into a solution of the chloride.

DETECTION OF BEEF FAT OR LARD IN BUTTER.—Mr. Stoddart gives the following method of distinguishing between butter and other fats of animal origin. A quantity, say fifty grains of butter, is put into an ounce bottle, half filled with ether, and the mixture is well agitated. If the butter be genuine, perfect solution of the fatty matter will take place, and salt and water will be separated, together with curd, which is occasionally present to the extent of eight or nine per cent. The salt and water may be readily recognized, and the curd may be proved such by heating a small portion on a slip of glass, when it will dry and fall to powder. If beef fat or lard be present, they will not dissolve in the ether, but fall to the bottom of the solution; by the application of heat, as in the case of curd, the fatty character of these substances is at once shown by their liquefaction.

PRAIRIE CHICKENS AND GRASSHOPPERS.—While naturalists and entomologists are puzzling over the discovery of some plan to prevent the recurrence of the grasshopper plague in the Western States during next fall, it would be well for them to take the immense yearly slaughter of the prairie chickens into consideration. The numbers of these birds which are slaughtered each winter by trapping after heavy snow storms, and find their way to the markets, are something enormous; and as the grasshoppers constitute a great part of their natural food, it seems not improbable that the disappearance of the former might exercise a very appreciable effect in the increase of the devastating insects.

The discovery of "plate glass," which was accidental, was made in the year 1688, by a man called Thevat. It is attributed to the breakage of a pot containing some of the melted material, a portion of which flowed under a large flag stone, which, when subsequently removed, was found in the form of a plate. This suggested the idea of casting it in plates; a patent was soon obtained, and works were established in Paris.

Every passenger-car on the Illinois railroads is by law compelled to be furnished with a woodman's ax, a sledge-hammer, a hand-saw and two leather buckets.

A SILVERING powder for coating copper consists of nitrate of silver 30 grains, common salt 30 grains, cream of tartar 3½ drachms. Mix, moisten with water, and apply.

DOMESTIC ECONOMY.

Hints for the Household.

A correspondent of the *Germantown Telegraph* furnishes the following "trifles" under the head of "Hints for the Household."

TRIFLES.—There are many little things in the household, attention to which is indispensable to health and happiness. The kind of air which circulates in a house may seem a small matter, for we cannot see the air, and not many people know anything about it; yet if we do not provide a regular supply of pure air within our houses, we shall inevitably suffer for our neglect. A few specks of dirt may seem neither here nor there, and a closed door or window appears to make little difference; but the little dirt and the little bad air are apt to sow the seeds of ill-health, and therefore ought to be removed. The whole of the household regulations are, taken by themselves, trifles—but trifles tending to an important result.

PREVENTIVE AGAINST MOTHS.—A very pleasant perfume, and also preventive against moths, may be made of the following ingredients. Take of cloves, caraway seed, nutmeg, mace, cinnamon and Tonquin beans, of each one ounce, then add as much Florentine orris root as will equal the other ingredients put together. Grind the whole well to powder, and put it in little bags among your clothes, etc. This will answer for furs also; but I never tried anything more certain as a protection against moths in furs than to first shake out or heat out every foreign substance before putting away for the season. Then wrap them up in a perfectly sound newspaper. What I mean by sound is that there shall be no holes or breaks in the paper. Make a bag of the paper by pasting; pack it and paste up the mouth of the bag. Put it in a drawer where it will not be disturbed. If well done not a moth will ever be found inside. Try it.

WASHING WOOLENS.—Professor Artus, who has devoted himself to the discovery of the reason why woolen clothing, when washed with soap and water, will insist upon shrinking and becoming thick, and acquiring that peculiar odor and feeling which so annoy housekeepers, says these evil effects are due to the decomposition of soap by the acids present in perspiration and other waste of the skin which the clothing absorbs. The fat of the soap is then precipitated upon the wool. These effects may be prevented by steeping the articles in a warm solution of washing soda for several hours, then adding some warm water and a few drops of ammonia. The woolens are then to be washed out, and rinsed in lukewarm water.

LEMON-PROPS FOR CHILDREN.—Squeeze the juice of six lemons into a basin; pound some lump sugar and sift it through a fine sieve; mix it with the lemon-juice and make it so thick that you can hardly stir it; put it into a stew-pan, and stir it over the fire for five minutes; then drop out of a teaspoon on writing paper and let it stand until cold.

TREACLE PIE.—Line a dish with thin paste, cover with treacle as for rolly-polly pudding, and continue alternate layers of paste and treacle till the dish is full, finishing with paste; bake in a moderate oven.

VIOLET POWDER.—Violet powder is made by scenting finely-sifted arrow root with a little orris root.

THE MOSAIC DIETARY LAWS.—It is strange that the Mosaic prescriptions for man's diet, chiefly taken from the tabernacle rites, have become, by common consent, the bill of fare of modern society, with variations, of course. In the cities, especially, the main articles of food are those which the laws of Moses recommend. When in former days people dieted largely on pork, many became hogs themselves, and many diseases, still raging among men, have been conveyed into the human system by the consumption of pork, rabbits, hares and other animal food which the law forbids.

Physiologists understand well enough the importance of diet, and yet none have gone to the trouble of giving the Mosaic dietary laws a thorough scientific examination. Here are the Jews, after 3,000 years, a healthy, intelligent, energetic and fertile race. Much is said about their longevity, temperance, charitable disposition, etc.; still no scientist has taken the trouble to examine the food on which this race lived and thrived. The point is certainly, scientifically, very important.

NEW METHOD OF CLEANING WOOLEN GOODS.—It is well known that wool when first taken from the sheep contains an innocuous secretion from the skin of the sheep called "yolk." This soapy substance contains potash, and can be washed out with water, with which it forms a sort of lather. In Elbeuf this yolk is employed with advantage as a substitute for fuller's earth in cleaning woolens. The raw wool is put in a large vat, and covered with water. Here it is left for three hours; then the water is let out into a second vat, and afterwards pumped back into the first vat for two hours longer. The operation is repeated two or three times, and then the wool is taken out of the vat freed of water. New wool is now put in the vat and manipulated as above, until the water is sufficiently soapy. The cloth is put in the fulling machine with a sufficient quantity of this liquor, and fulling for two or three hours. After washing it is found to be perfectly clean.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Short Lectures on
Patents: A New Style of Dry Ore Crusher, 361.
Mining Education—Practice and Theory; Reworking
Old Mines: Memorial Day; The Coming Exhibition;
Exhaust Steam and Draft, 368. Test; Notices of
Recent Patents, 369. Patents and Inventions; Gen-
eral News Items, 372.

ILLUSTRATIONS.—McFarland's Patent Dry Ore
Crusher, 361. Economy of the Vegetable Kingdom,
366. Cultivation of Tea, 369.

CORRESPONDENCE.—Mineral City Mines, 362.
SCIENTIFIC PROGRESS.—Sensations Produced
by a Lightning Stroke; Diamonds from Sugar; Inter-
esting Discovery: The Evaporation of Metals by
Electricity: Interesting Fact; Interesting Archaeo-
logical Discovery; Magnetism of Railways; A Boiling
Lake; Steel vs. Iron Rails; Utilizing Wave Power;
Triumphs of Science: Progress of Russia in Manu-
factures and Art; Hydrogen Gas in Iron; American
Iron Ship Building, 363.

MECHANICAL PROGRESS.—What Steel Is;
Experiments on Steel—Magnetism and Carbon; To
Prevent Cars Jumping from the Tracks; Steam; Mas-
tic for Iron and Other Materials; Channelled Nails;
Casting Steel, 363.

MINING SUMMARY from the various counties
in California, Nevada, Oregon, Utah, Colorado and
Idaho, 364-5.

POPULAR LECTURES.—Economy of the Vege-
table Kingdom, 366.

USEFUL INFORMATION.—To Form Perfect
Squares; To Preserve Posts; Alcohol—Curious Change
of Meaning; Ballooning; Waterproof Paper; Detection
of Beef Fat or Lard in Butter; Prairie Chickens and
Grasshoppers, 367.

GOOD HEALTH.—Fetid Feet; Salicylic Acid—The
New Disinfectant; Sunflowers for Fever; Cure for
Cholera; Cholera in Sea-Sickness; Remedy for
Lockjaw, 367.

DOMESTIC ECONOMY.—Hints for the House-
hold; The Mosaic Dietary Laws; New Method of
Cleaning Woolen Goods, 367.

MINING STOCK MARKET.—Sales at the San
Francisco Stock Board; Notices of Assessments;
Meetings and Dividends; Review of the Stock Mar-
ket for the Week, 372.

MISCELLANEOUS.—Affairs at Panamint; About
Arizona Mines; The Grave of Comstock; Calaveras
Gravel Mines; Tin in Powder; A Mine in a Post Hole;
Origin of the Nitre Beds of Peru; A Light without
Fire; Improved Freight Car, 362. Coal Railroad
Items; Quicksilver Mining and Its Profits; The In-
ventor's Paradise, 366.

Monthly List of Scientific Books.

[Published the first issue in every month.]

The above list is compiled and the works are for sale by A. L. Banoroff & Co., Scientific Booksellers, 721 Market street, San Francisco.

The California clay manufacturing company own a tract of land on Cook's ranch, on the line of the California and Oregon railroad, one mile beyond Lincoln, where they are now preparing to work about two hundred acres of clay and coal lands. This clay is said to be of the best quality yet discovered on this coast, and the company think it will prove an important industrial addition to the State, and of great advantage to all pottery-makers. Examination of it has been made by H. G. Hanks, who speaks of it in high terms. He finds its character to be the very best for pottery work of all classes, and one quality excellent for fire brick.

The new steamer built at Marysville for the navigation of the Sacramento and Feather rivers, which is to run between San Francisco and Marysville, was successfully launched on the 29th ult.

During the month of May the mint in this city coined of double eagles, \$2,140,000; trade dollars, \$535,000; quarter dollars, \$119,000; total \$2,719,000.

Mining Education—Practice and Theory.

The art of mining must, to a large extent, be learnt at the mine, both underground and at the surface. The diligent student will however obtain much aid from external sources, and obtain considerable elementary knowledge of the principles and facts of mining from works which are suitable to teach young miners what to observe and how to interpret these observations. The young student should endeavor to add to his own limited experience the wider experiences of men in many countries, by reading as well as by conversation with those having more experience than himself. He should also accustom himself to make written notes of the peculiarities of all mineral deposits with which he may become acquainted, and of the construction, cost and comparative efficiency of all tools, machinery and materials which may come under his notice.

The common notion that practical mining can and ought to be taught in a school of mines, and the instruction that would be given in such a school should stand in lieu of practice in mining works, is, it is needless to say, erroneous. Only in a mine and in the midst of mining works can the student obtain that technical knowledge without which all that he can learn in a mining school is valueless to him in his profession. These schools are intended to add to the knowledge of the practical miner and to encourage him to study those branches of science which are almost indispensable aids to practice, but which cannot stand as substitutes for it.

It is a mistaken notion to think that the practical man is the only one whose knowledge is to be trusted; it is none the less a mistaken notion to think that the theoretical man is the only one whose knowledge of mining is worth anything. In mining more than anything else, practice and so-called theory go hand in hand. The truth is that in most cases the theoretical man are called so because they have a wider range of knowledge than the mere practical man can by any possibility gain, as his knowledge comes from experience alone, and he ignores the experience of others. The theoretical man stores in his mind the experiences of many practical men, and with these as a superstructure to the basis formed by the so-called "book learning," his knowledge is more full and ripened than that of the working miner. There is really no antagonism between the two classes, as each gains by the knowledge of the other. The fund of information possessed by the scientific man is enriched by contact with the practical man, and the experience of the latter becomes more valuable to him by learning the reasons for things which he has heretofore taken for granted without inquiring the why or wherefore.

To become proficient, therefore, in the art of mining, the student must have a thorough grasp for the foundation, and the basis consists mainly in a good knowledge of laboratory work, acquaintance with the rocks and minerals, and some general ideas of the principles and facts of mining. It will then be better for him, before proceeding to advanced studies, to go to the mines, become familiar with surface and underground work, learn the reasons why certain things are done and the results practically, study and watch the machinery and metallurgical details, compare the systems in use in different mines; and during all this time keep notes of all items of interest likely to be valuable to him.

After spending as much time as convenient in this practical work, he will be better able to comprehend the details explained to him in his books, and also gain a definite idea of the class of knowledge most important for him to attain. He will become, moreover, more interested in a business with which he has some practical acquaintance, and instead of his studies appearing mere dry facts they will be more energetically followed, as so much capital to be drawn on an occasion requires in active life. On his final retirement from scholastic duties, and his commencement of practical work, the young miner will find that his store of knowledge, both in theory and practice, can be wonderfully increased, and he will endeavor to increase it in both directions as rapidly as possible. Practice alone will fire one of the drudgery, and theory alone will show the student the difficulties he must eventually overcome; but a judicious intermingling of both theory and practice in mining education will make a good miner, one who is theoretical and practical at the same time.

At the Chollar Potosi mine the grading for the site of the new shaft is completed, and the erection of the heavy stone walls for securing the embankments have been commenced. The first set of timbers for the shaft have been framed, and are of the best character of red spruce, fourteen by sixteen inches square. It is intended that no other kind of timber shall be used in the shaft, as that is considered the firmest and best that can be obtained. The entire supply of timbers for the shaft will be brought from Alta and Blue canon, California.

In the anthracite coal counties of Pennsylvania 450 persons were killed and 1,312 more or less hurt in the mines during the five years ending with 1874.

Reworking Old Mines.

There is no more encouraging sign of the advancement of the mining interests of California than that afforded by reading the numerous notices of renewal of work on mines which have been abandoned in former years. It is not in a few isolated instances only that this has occurred, but it is becoming so frequent as to cause little comment. In all the old mining counties of the State there are hundreds of abandoned shafts and tunnels, which were left by their owners years ago when miners looked for what the surface afforded and did not care to sink very deep. Frequently these claims were abandoned because the owners found out suddenly that it required hard knocks to get out gold, and that it did not come in lumps as they had fondly anticipated in coming to California. Again, they were abandoned because the miners rushed for new excitements where they hoped to make their fortunes in a few days. In other cases the claims were left for want of capital and proper milling facilities to work them, and sometimes also because the owners became discouraged before striking the lead.

Of course no one can tell in any of these claims just how much work must be done before the investor gets his money back. Still there are now plenty of persevering men re-opening these abandoned mines, and in many cases they have struck it shortly after commencing work. Only this week we learned of an instance of this kind which occurred in Sierra county. A long tunnel had been run into a hill by former owners with the expectation of tapping a ledge low down. It was run much further than was originally intended, but as no ledge was found the miners came to the conclusion that there was nothing of it at that depth and gave up the enterprise. The claim laid idle some eight years, but recently a new company relocated the ground, cleaned out the tunnel, retimbered it and started work in the face. They had only run 40 feet when the ledge was struck, and struck rich, too. Instead of pitching at the angle calculated by the original owners, it pitched at a much greater angle. The present owners are now only waiting for a patent for their ground to commence operations on a large scale.

The Oroville Mercury of last week mentions another circumstance of the same kind, at the old Porter mine on Jordan hill, about five miles from Yankee hill. This mine is now owned by an English company, who are engaged in re-opening the old tunnels and drifts with a view of again having it worked. Last week the men in the tunnel struck the ledge at a depth of 250 feet and found it to be as rich as any of the owners could wish. There is an old 12-stamp mill near the mine that has not been used for some seven years, and the building is in a dilapidated condition, but now the owners will put it in good repair and prepare to crush the rock. The ledge formerly paid well, but pinched out. Now that they have struck it so deep they think it will last.

As a contrast to this abandonment of claims under discouraging circumstances, may be mentioned the perseverance of a miner, spoken of by the Plumas National. Some nine years ago a Frenchman, whose name we could not learn, started a tunnel into the face of the mountain in a place known as Brown's diggings, in the southern part of Plumas county. He was advised, as usual, that he "was fooling away his time," but persevered, and the sound of his pick could have been heard at almost any time since, as he made his slow way through the hard rock. About the first of last January he broke into gravel, and since then he has taken out about \$2,000, and his chance for a big fortune is reduced almost to a certainty. We like to chronicle the success of just such men as this Frenchman, who back their judgment with their muscle, and overcome the obstacles in their path by "hard knocks."

Memorial Day.

Memorial day was generally observed throughout the country—not a city or a hamlet but its flags were lowered and its people did homage to the memory of those brave souls whose bodies were offered a sacrifice to maintain the nation's honor.

There is something sadly beautiful in the idea of a nation dressing the graves of her dead heroes with mournful emblems of respect and love. The memories this day awakens are not all sorrowful. The knowledge that those we loved and lost fell in defence of a great and pure principle will heal the hearts that would bleed afresh, check the sorrows that would otherwise be incurable. One of the most cheering evidences of the truth of our country is found in the reports that come to us of the mingling and interchange of comrades among those who not more than a decade since stood opposed in mortal combat. Over the grave of their dead brothers, the Union and Confederate clasp hands and swear allegiance to a common cause, for

"Under the sod and the dew,
Waiting the judgment day,—
Love and tears for the blue,
Tears and love for the gray."

In San Francisco the ceremony of decorating the graves at the cemetery was attended during Saturday, under the auspices of the Grand Army of the Republic, and in the evening Pacific Hall was crowded to repletion with ladies and gentlemen who listened to an appropriate memorial address delivered by Governor Pacheco.

The Coming Exhibition.

As time draws on towards the date of opening the Tenth Industrial Exhibition of the Mechanics' Institute, we are glad to find our manufacturers alive to the importance of the event. The Secretary, Mr. Culver, reports a large number of applications for space already filed, and from present appearances the capacity of the pavilion will be taxed to its utmost to afford space for a proper display of the different articles. Up to the first of the week over 30,000 square feet had been applied for. In the list of noticeable applications is that of the managers of the Cornell watch factory, who propose to have their mechanics at work, that the public may see the whole process of making a watch. The Turbine windmill company will have one of their windmills in operation, the agitating power being furnished by a blower provided for the purpose. Mr. W. W. Hanscom, proprietor of the Hope iron works, will exhibit a steam yacht. He makes a specialty of this branch of naval architecture. Mr. L. W. Coe has engaged space for an exhibition of the practical working of his air compressor and rock drill. The California furniture manufacturing company will make a fine display of house and office furniture. The California silk company will show silks and ribbons of their own manufacture. The Kimball manufacturing company have applied for a large space, in which to make a display of carriages, light wagons, cars, etc. Messrs. Roman & Co. intend making a show of their varied stock of school furniture. Clark & Co., a new firm from Illinois, who have commenced the manufacture of organs in Oakland, desire space for introducing their instruments to the notice of the public. The portion of the building reserved for mechanics is being rapidly taken up, and we expect to see the best display in that line ever attempted in San Francisco.

As by this time most everybody knows, the exhibition will open on the 17th of August next. Application for space should be made direct to J. H. Culver, Secretary, No. 27 Post street.

A regular meeting of the Board of Trustees of the Mechanics' Institute was held on the 1st inst. President Hallidie, who returned from his European trip on Monday night, was in the chair. Mr. Hallidie has made a flying trip of one hundred days, and returns to work refreshed by his relaxation from business. At the above meeting, in connection with the annual election on next Monday evening, Charles H. Grønnehsen, Wm. Renny and John O. Hanscom were appointed Judges of Election; Geo. L. Hull, R. A. Marden and Wm. Freer, Clerks of Election; Geo. C. Hickox, H. J. Booth and J. R. Wilcox, Installation Committee. Messrs. Spiers, Wells and Davis were appointed a Committee for the general management of the election. The annual election will be held on next Monday, from 12 m., to 6 p. m., and from 7 p. m., to 9 p. m. The annual meeting of the Society is held June 5th, when the reports of the officers for the year will be presented.

Exhaust Steam and Draft.

A subscriber asks us how the action of exhaust steam in producing a draft in a locomotive chimney is explained. Colburn's Locomotive Engineering explains simply as follows: The exhaust steam escapes from the cylinders through one or two contracted openings or exhaust nozzles which point directly up the chimney or smoke stack. The exhaust steam escapes from this orifice with great velocity and expands as it rises, so that it fills the pipe and smoke stack. It thus acts somewhat like a plunger or piston forced violently up the chimney, and pushes the air up above it, and owing to the friction of the particles of air carried that which surrounds it along up the stack, from which it all escapes finally into the open air, thus leaving a partial vacuum behind in the smoke box. The external pressure of the atmosphere then forces in air through any and every opening in the smoke box, to take the place of that already drawn out or exhausted from it. As the only inlet is through the tubes, to which the gases of combustion have free access from the fire box, and as the external air can only pass through the fire box and through the burning fuel to reach the fire box, there is a constant draft of air through the grate as long as the waste steam escapes from the blast pipe and up the chimney. It is thus, that within certain limits, the more the steam is required the more steam produced; for all steam used in the engine draws in the air in its final escape, to excite the fire to generate more steam.

This is the most economical and convenient way of creating a strong draft, as locomotive engine boilers have to produce more steam in a given time, in proportion to their size, than is required of any other class of boilers (except, perhaps, those of steam fire engines), because the space and weight allowable for locomotive boilers is limited. So by creating a very strong draft of air through the fire and then passing the heated air and products of combustion through a great many small tubes surrounded by water, the heated gases are divided into small streams, and the steam generating capacity of locomotive boilers is increased above that of marine and stationary boilers.

Tea.

Cullivallon and Preparation for Market, and Extent of the Trade.

From the fortunate geographical position of the city of San Francisco, it is destined to become the future tea market of America and Europe. For America, it must be the great distributing center, because of its position with regard to China, and to America, North and South. The sea voyage to China and Japan is the shortest and best that can be made from the east of Asia to the west of America, and the parallels of latitude between which it lies are those in which the temperature and weather are best suited for preserving tea on a sea voyage. Further north or south, there is not only a longer voyage to be undertaken and rougher weather to be encountered, but there are either great tropical heats or cold wintry spells with their inevitable concomitant of sea damps to be encountered. This alone will prevent any large cargoes of tea from ever being taken to ports further north or south as depots for supplies, and will also neutralize to a great extent the effect which the opening of the route across the isthmus of Panama by the cutting of the proposed canal might entail. Then the great railroad which unites this city with the empire city of the East, brings us at once into contact with every great

planted to fresh ground. After the third year picking commences and, though the leaves are freshly picked each season, yet the plant thrives, and lives about as long as men usually do. It is never entirely stripped, but every spring those bright green leaves are taken which have just appeared on the top of the bush. The other leaves, and even those of simply the last year, are never gathered, except, perhaps, to make the cheapest kind of tea for poor folks. The finest quality of tea, and that which costs here several dollars a pound, is made up entirely of those delicate little shoots found at the tip end of the stems, just as the tiny leaf is in process of forming. These minute shoots are always carefully picked at first, and the leaves just below them are gathered afterward. The time to begin picking is usually in May, and it continues at various

process is repeated twenty times or more, and it is far more laborious than might ever be supposed. Gradually the leaves become dryer and darker in color, and after the last rolling they are spread on moderately warm pans for awhile, and then placed in large baskets. On an average one man will roll and dry in a whole day as many leaves as would fill an ordinary tea-chest.

[Conclude next week.]

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

FRUIT DRIER.—Levi A. Gould, Santa Clara,

PLANTING OUT IN THE THIRD YEAR.

intervals for two months, according as the new leaves make their appearance, the teas from the first being known as Garden or Bud teas. Our illustration shows women and girls employed in the work, which is light and pleasant. When the baskets are full they are taken to a long, low house, where several men are silently at work and where they are prepared

Santa Clara county, Cal. Mr. Gould's invention is intended for drying fruits, vegetables and other substances. A closed room, box or tank is supported above the ground or floor, so that a clear space will be left below, for the purpose hereinafter described. The interior of this box or drier forms a single chamber, but in order to permit the use of frames or trays of

trays and the trays arranged in the tracks, the air which is forced into the front end of the box, after becoming heated by the hot pipes, will be forced upward by the partition through the fruit which was last introduced through the doors. In its passage upwards the hot air will become saturated by the moisture abstracted from the fruit, so that by the time it has arrived at the top of the chamber it will be so heavy with moisture that it will begin to descend towards the rear of the chamber.

A short distance back of the partition openings are made in the floor of the chamber, and in the rear end of the box or room other openings are made near the floor. The hot air, heavily saturated with moisture from the fruit, settles directly down through the openings in the floor and passes away underneath the apparatus, while that portion which is less saturated with moisture passes out through the other openings in the rear. It will thus be seen that the dry, hot air is compelled to pass directly upward through the green fruit, so as to rapidly take away its moisture. It then descends at an angle through the portion of fruit which has been previously passed through the front portion of the chamber, disposing at once through the openings with the portion of air which is very heavily saturated with moisture, and allowing that portion which is less saturated to travel towards the rear end of the chamber. The inventor claims that this mode of applying the hot air to the fruit or other substance will take away the excess of moisture and at the same time leave the fruit in a thoroughly preserved condition, without cooking or burning it. It is desirable that the moist air in descending from the top of the chamber to the discharge openings should come as little in contact with the fruit as possible. The inventor therefore extends the side

Working the Leaves.

rails or strips of the trays a few inches beyond the rails, so that these openings will prevent the trays from coming together and thus provide a space of three or four inches between each two trays, through which the moist atmosphere can pass freely in its descent from the top of the chamber. The tracks on which the trays move should descend slightly from the front to the rear, in order to allow the trays to move easily. In making a small portable drying apparatus, a stove can be used for supplying the heated air. It will be noticed that the chief feature of this invention is the bridge wall or partition for directing the current of heated air up through the fruit, and the openings through which the moist atmosphere is discharged.

IMPROVED STUD FASTENING.—Salle Zacharias, San Francisco, Cal. This is an improved fastening for securing buttons, studs, and other articles of jewelry in button holes, and it consists of an arrangement by which the shank of the stud or button can be readily introduced into the button hole and fastened without stretching or distorting the hole or rumpling the material of the article of apparel in which the button or stud is secured. In a cuff button, for instance, the button has a

Cooling.

shank of the desired length to extend through the thickness of the article. On this shank is secured a rotating sleeve which has a wing upon opposite sides, so that the sleeve with its wings will fit in the button hole without unduly stretching it. On the outer end of the sleeve is secured an oval disk, and on the outer end of the shank is a corresponding oval disk, so that the sleeve with its disk can rotate on the shank between the button and disk, the two disks lying together. On the inner end of the sleeve is secured a spring which extends out along the under side of the button head until its extremity projects slightly beyond the rim of the button. A notch or equivalent catch is formed at each quarter of the head, so that the spring will be stopped by each one as the button rotates. By pressing the extremity of this spring down with the finger, the head can rotate so as to prevent the spring from entering any of the notches, but it can be stopped in either of the notches desired. To secure the button in the button hole the two disks are made to lie in the same direction, one upon the other, by changing the spring to the proper notch. The disks are then passed through the button hole, when, by depressing the spring with the finger, the button can be rotated one quarter of the way around until the spring drops into the next notch, so as to turn the disk on the opposite or inner end of its shank across the other disk and thus secure the button in place.

The Tea Plant.

commercial city in the United States, from the great lakes and the St. Lawrence to the Gulf of Mexico, and from the Atlantic to the Pacific oceans. And it is certain that sooner or later, that railroads will connect this city with every point on the continent of South America, and the voyage by sea to San Francisco, by rail to New York, and by sea again to any part of the Old World, is far preferable in the important item of preservation of quality and prevention of loss by shipwreck, to that by sea direct from China and Japan. By and by, doubtless, the tea trade of China with Europe, will be carried on over transcontinental railroads that shall straddle the Old World, but here this takes place a century must have elapsed; meanwhile the teas of Asia will reach Europe across the American continent. The tea trade of Europe and America is now over three hundred million pounds, worth one hundred and fifty million dollars per annum. San Francisco must become for China the depot and trade center of this vast commerce. In the not distant future, ere a quarter of a century has rolled over our heads, our tea business will be so vast that its docks, wharves and warehouses will occupy one entire section of

Sifting.

our city, and fleets constantly arriving and discharging will crowd our water front. Californians are therefore interested in information concerning tea, and we here present the first installment of an article, embodying a few general facts concerning tea culture and trade.

The illustrations accompanying this article are copied literally from original paintings by a Japanese artist. They show the various stages of tea culture in that country as described by Prof. Clark in the *Christian Weekly*, from the picking of the leaf under the shadow of the sacred mountain Fusi Yama, through all its curing processes, till it is ready for use and sale. The methods employed are described by Prof. Clark from personal observation.

The tea fields are scattered throughout the country, ranged mostly along the hillsides, or, when found on more level ground, they are mingled among other forms of vegetation. The tea bushes are not more than breast high even at their full growth, and the young plants are quite small. When first set out they are planted in circles, the center of which are filled with manure, and in places where they are liable to be damaged by frost they are covered. At the end of the third year they are trans-

PICKING THE LEAVES.

for market. The work of preparation differs in different localities. Our illustration represents the placing of the leaves in small quantities upon a series of stout pasteboard trays or pans, set upon brick ovens containing smoldering embers of charcoal and straw. These queer looking pans are ranged in rows, and are

small size, the inventor frequently constructs two or more parallel tracks inside of the chamber, by securing upright posts at intervals through its middle, and to these posts is secured one rail of each track, while the opposite rails are secured to the walls of the chamber. As many tracks can be arranged, one above the

Oven and Pans.

maintained at various temperatures, so that the hand can barely be put on the hottest. In front of each of these pans represented in our illustration, stands a man working the leaves between his hands and spreading them back and forth, to keep them equally heated.

It is here that the real work of the tea-making process is seen. These men stand from morning till night over these slow fires, rubbing and rolling the leaves between their hands continually. The leaves are placed on the hottest pans first, and when they are moist and green; but after being rolled some time and partially dried, they are allowed to cool on straw mats, and then they are placed on a second pan and rubbed and rolled again. This

Heating on the Ovens.

other, as the height of the chamber will permit. The lowermost track or trays in the chamber are at least three feet above the bottom or floor of the chamber, thus providing a space between the floor and the lowermost tracks, across which a transverse partition extends about six feet from the front end of the room or box in the manner of a bridge wall. This partition extends from the floor to the lowermost track. Doors in front admit the trays and others in the rear allow them to be removed after passing through the chamber on the tracks. Below the tracks, in front of the partition, is a coil of steam or hot air pipes. Air is forced into the space in which the pipes are coiled. The fruit to be dried having been properly placed on the

THE TURBINE.

**Simplest, Cheapest,
and Most Durable.**

The Inventor of the Dexter Windmill has made new
and useful improvements in Windmills, patented March
16th, 1874, and now feels confident of having the
SIMPLEST, CHEAPEST, MOST DURABLE, and

**ONLY PERMANENT WINDMILL
IN THE WORLD.**

SIMPLEST, because it is less complicated; CHEAPEST,
because it never needs repair, standing on a firm founda-
tion; MOST DURABLE, because it is all under cover,
and has less rigging to get out of order; ONLY PERMA-
NENT, because the only Windmill in the world that has
never been injured by storms. Hundreds of people,
who have thought the Dexter perfect, will be glad to
observe the SUPERIORITY OF THE TURBINE over
all predecessors. Although much improved, the price
of Mills remain the same as formerly. Persons who
study their own interest will investigate the TURBINE
before purchasing any other.

Territory for sale outside of California, at reasonable
rates and easy terms.

Mills built to order of the best material, and at the
shortest notice, by Kimball Manufacturing Company,
corner Fourth and Bryant streets, San Francisco. Any
orders sent to their address will receive prompt atten-
tion.

For further information regarding Mills or Terri-
tory, send for New Circular. Address,

A. H. SOUTHWICK,

This is a Sure Cure for Scab, Worm, Scab
and Foot Rot in Sheep. It also kills Ticks,
lice, and all Parasites that infest Sheep.

Prevents scratching and greatly improves the quality
of the wool. One gallon of the Dip properly diluted
with water will be sufficient to dip one hundred sheep,
so that the cost of dipping is a mere trifle, and sheep
owners will find that they are amply repaid by the im-
proved health of their flocks.

This Dip is guaranteed to cure when used according
to directions, and to be vastly superior to Corrosive
Sublimite, Sulphur, Tobacco, and other remedies which
have heretofore been used by farmers.

Circulars sent, post paid, upon application, giving
full directions for its use, also certificates of prompt
cure. Sheep growers who have used large quantities of the
Dip, and pronounce it the most effective and reliable
known Cure and Preventive of Scab and other kindred
diseases in Sheep,

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Manufactured by California Brass Works, 125 First street, S. F. 24v23

JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidity pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merit. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Sellers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., June 1st, 1875.

FOR WEEK ENDING MAY 18TH, 1875.

MACHINE FOR REMOVING BROKEN DRILLS FROM HOLES.—John W. Platt, Mineral City, Nevada.

SASH BALANCE.—John J. Price, S. F., Cal.

WAVE POWER MACHINE.—Charles Buckner, Jr., S. F., Cal.

WATER VALVE.—Anthony Chahot (two cases), S. F., Cal.

TRAIN TELEGRAPH.—Alban N. Towne, S. F., Cal.

TRADE-MARK.

FOR MEDICINE.—Yerba Buena Bitters Company, S. F., Cal.

These patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

General News Items.

The Committee of the New York Board of Trade on postal affairs having received information from a large number of merchants in New York that the postal expenses on newspapers and letters under the new law have doubled, will soon confer with Postmaster General Jewell and the Postmaster of New York upon the measures necessary for the repeal of the obnoxious law.

A TERRIBLE calamity occurred at Holyoke, Mass., last Thursday evening. The Catholic church took fire during service, and 75 men, women and children were killed, either burned to death or trampled under foot by those who escaped from the building.

The total value of imports of silk manufacture at New York in May was \$1,315,039. During the same time 1,062 packages of raw silk were received, of which 856 were via Panama, 20 via overland routes, and 186 from Europe.

The express office of Wells, Fargo & Co., at Quincy, Plumas county, was entered on Monday night by parties unknown. The safe was taken from the office, cut open, and robbed of \$2,800 in coin and treasure.

They have an immigration bureau in Kern county.

GEN. COEY has been presented with a gold medal.

The huge, drastic, gripping, sickening pills, constructed of crude, coarse and bulky ingredients, are fast being superseded by Dr. Pierce's Pleasant Purgative Pellets, or Sugar-Coated Concentrated Root and Herbal Juice, Anti-Billions Granules—the "Little Giant" Cathartic or *Mulm in Parvo Physic*. Modern Chemical Science enables Dr. Pierce to extract from the juices of the most valuable roots and herbs their active medicinal principles, which, when worked into little Pellets or Granules, scarcely larger than mustard seed, renders each little Pellet as active and powerful as a large pill, while they are much more palatable and pleasant in effect.

Dr. Ira A. Thayer, of Baconsburg, Ohio, writes: "I regard your Pellets as the best remedy for the conditions for which you prescribe them of anything I have ever used, so mild and certain in effect, and leaving the bowels in an excellent condition. It seems to me they must take the place of all other cathartic pills and medicines."

LYON & MACOMBER, druggists, Vermillion, D. T., say: "We think they are going to sell like hot cakes as soon as people get acquainted with them, and will spoil the pill trade, as those that have used them like them much better than large pills."

Tenth Industrial Exhibition of the Mechanics' Institute, S. F., 1875.

PRELIMINARY ANNOUNCEMENT.

The Board of Managers of the Tenth Industrial Exhibition have the pleasure of announcing that an Industrial Exhibition will be held, under the auspices of the Mechanics' Institute, in the city of San Francisco, to be opened on Tuesday, the 17th of August, 1875, at 11 A. M., and to continue open at least one month thereafter.

In making this public announcement, the Managers desire that those who intend to exhibit should send in their applications for space as early as possible, so as to avoid the necessity of excluding, as has been the case heretofore, the many desirable exhibitors who are unusually tardy in making applications.

The forthcoming Industrial Exhibition will be the tenth held under the auspices of the Mechanics' Institute, and the Managers are justified in saying that it will undoubtedly surpass in completeness of detail and general arrangement any heretofore held.

The last Exhibition was attended by 700,000 visitors, attracted hither by the fame of these Industrial Fairs, and for the purpose of investigation, business and pleasure.

All the available exhibiting space was applied for several weeks before the day of opening, and the Managers were compelled to deny admission to many desirable exhibitors.

The Board of Managers desire particularly that the arts, the industries and natural products of the country should be well represented at the forthcoming exhibition, and no pains will be spared to make these classes of exhibits a special feature there.

The Exhibition will be held in the building constructed for that purpose in 1874, but it will be materially enlarged and improved in many details for this Exhibition of 1875.

The space under roof will cover 180,000 square feet, or about four and a half acres, exclusive of the Horticultural Garden, which will occupy 24,500 square feet additional.

The location of the Exhibition Building, on Eighth street, between Market and Mission streets, cannot be surpassed for convenience and accessibility, and can be approached from every part of the city by means of the various lines of street railroads, any of which bring visitors within two blocks of the entrance gate.

The utmost care has been exercised in providing for ample ventilation and light, and during the evening the building is brilliantly illuminated by over 5,000 gas lights.

The promenade avenues are broad, and 3,000 seats are provided for the comfort of visitors, and for convenience there is also an excellent restaurant, under the management of a first-class restaurateur.

Every afternoon and evening the best orchestra the city can apply will discourse excellent music under the direction of an accomplished leader.

The building is always well attended by visitors, and during the last Exhibition over 25,000 were daily admitted for admission and under no similar circumstances can the manufacturer, the mechanic, the inventor, producer or business man so advantageously place himself before the people of the Pacific Coast.

Persons desiring to obtain information, or to make application for space, should address "Managers of Tenth Industrial Exhibition, San Francisco, California," or make personal application to the Secretary.

It is expected that the various transportation companies will convey goods intended in good faith for exhibition, at half the usual rates.

Exhibitors from abroad, if they have no agent or consignee in San Francisco, can consign goods and mark the same to the "Manager of the Tenth Industrial Exhibition, 17 Post street, San Francisco," and they will be stored, if they arrive before the day of opening, free of expense; but no charges or expenses for freight or forwarding, etc., will be paid by the Managers.

In order to secure space, application should be made on or before July 20th, 1875.

Blanks will be furnished on application.

Medals will be awarded as follows, viz: 16 gold medals, 50 silver medals, Society Diplomas, Certificates of Merit and Special Premiums, as the Board may determine.

Blanks for space can be obtained at the Mechanics' Institute on application by letter or otherwise; and any information will be given, by applying to any member of the Board of Managers, as below:

A. S. HALLIDAY.....113 Pine street.
JAMES B. THAYER.....122 Battery street.
W. L. DAVIS.....421 California street.
D. E. HAYES.....213 Fremont street.
ASA R. WELLS.....Mechanics' Mill.
P. B. CORNWALL.....Cor. Spear & Harrison streets.
CHAS. ELLIOT.....516 California street.
GEORGE SPAULDING.....414 Clay street.
EDWARD SAVAGE.....139 Fremont street.
W. P. FROM.....504 Market street.
J. H. MACDONALD.....217 Spear street.
J. P. CURTIS.....320 Jackson street.
R. B. WOODWARD.....Woodward's Gardens.
JAMES SPIES.....311 Howard street.

To the Librarian of the Mechanics' Institute, or to J. H. OULVER, Secretary, 27 Post street, San Francisco.

Rules and Regulations of the Tenth Industrial Exhibition, Mechanics' Institute, S. F., 1875.

1. The Pavilion will be open for the reception of goods on Monday, August 2d. The exhibition will be open to the public on Tuesday, August 17th, at 11 o'clock A. M.

2. Applications for space must be made on or before July 20th, stating character of exhibit, amount and kind of space required—wall, table or floor. And if cases, state length, width and height of cases. Blanks will be furnished for this purpose, and a clerk will be in attendance at the Library of the Mechanics' Institute, every day from 12 to 1, and 7 to 10 P. M.

3. All persons presenting articles for exhibition must have them registered by the Receiving Clerk, who will give a receipt for the same, which receipt must be presented when the articles are withdrawn, at the close of the Exhibition.

4. Judges will be appointed by the Board of Managers, immediately upon the opening of the Exhibition, to examine all articles presented, in accordance with Article III, and the Managers will award premiums on such articles as the judges shall declare are worthy, which will be delivered as soon as they can be prepared. Due notice will be given of this announcement of premiums.

5. The mornings of each day, until 10 o'clock, will be appropriated to the Judges, and no visitors will be admitted during the time so appropriated, except at the special request of the Judges, or by permission of the Managers.

6. Articles intended for sale may be labeled accordingly, but cannot be removed until the close of the Exhibition, except by written permission of the Managers.

7. Steam power will be provided, so that machinery of all kinds may be seen in actual operation, and every facility possible will be given to exhibit working machinery to the best advantage.

8. The name of every article must be attached by the exhibitor to it.

9. Articles intended for exhibition must be entered and placed on exhibition on or before Saturday, August 21st.

10. Perishable articles will be received, or may be removed at any time during the exhibition, with the consent of the Managers.

11. The most efficient means will be taken, through the agency of the Police and otherwise, to guard and protect the property on exhibition; and it will be the purpose of the Managers that all articles shall be returned to the owner without loss or injury. Still, all articles deposited will be at the risk of the owners.

12. In case of any misunderstanding, application may be made to the Managers, who will at all times be in attendance.

13. The Managers are desirous that articles should be exhibited early. Those from abroad intended for exhibition, should be properly packed, and if not consigned to exhibitor's agent, must be marked, "MANAGERS OF TENTH INDUSTRIAL EXHIBITION, SAN FRANCISCO, CAL." All articles thus received, arriving too early, will be stored free of cost to the exhibitor, and the Managers will have them displayed in proper position for exhibition. No freight charges will be paid by the Managers; but exhibitors are notified that arrangements are being made with various transportation companies to repay freight charges on evidence of goods exhibited.

Information will be furnished by addressing MANAGERS OF TENTH INDUSTRIAL EXHIBITION, SAN FRANCISCO, CAL.

UNITED STATES

Mineral Land Laws, Revised Statutes,

And Instructions and Forms Under the Same.

We have just issued a pamphlet containing the general mineral land laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870; Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registrar's Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. General Land Office Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of MINING AND SCIENTIFIC PRESS, S. F.

N. B.—We have also added to the above publication, the REVISED STATUTES OF THE UNITED STATES, so far as relates to Mining Laws.

Mining and other Companies.

California Consolidated Mill and Mining Company. Location of principal place of business, San Francisco, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment levied on the 1st day of April, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

DUNBAR'S WONDERFUL DISCOVERY.

BETHESDA MINERAL SPRING WATER Of Waukesha, Wisconsin.

We claim Bethesda to be a specific in all cases of Diabetes, Inflammation of the Kidneys, Inflammation of
the Neck of the Bladder and Urethra, Inflammation of the Bladder, Dropsy, Gouty Swellings, Stoppage of Urine,
Albumenuria, Ropy or Cloudy Urine, Brick Dust Deposit, Thick, Morbid, Bilious and Dark Appearing Urine,
with Bone Dust Deposits, Burning Sensation with Sharp Pains when voiding Urine; Hemorrhage of the Kidneys,
Pain in the Kidneys and Loins, Torpid Liver Indigestion, Calculus, and Female Weakness.

There is no remedial agent known to man that can cure the foregoing diseases as effectually as Bethesda
Water. This fact has been demonstrated wherever the water has been used according to directions, which can
be had at the General Agents' by application to them. The water is sweet and pleasant to the taste. It can be
drank at all hours. Why should any one suffer while this Water is so easily obtained?

- The Cloverdale Quicksilver Mining Company, Sonoma County.
- The California Borax Company (Sniphur Banks), Lake County.
- The Abbott Mine, Lake County.
- The Buckeye Mine, Colusa County.
- The Cerro Bonito Mine, Fresno County.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

(PATENTED MAY 26TH, 1874.)
Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid
increase in our orders, our Pittsburg Manufacturers
have been compelled to add largely to their works—
a new gas furnace and heavier trip hammer—and are
thus enabled to reduce the cost of steel and at the
same time produce SHOES AND DIES superior to any yet
manufactured. We have consequently reduced the
price to 16 cents per pound and solicit a trial order,
guaranteeing that you will find them at least 10 per
cent cheaper than the best iron. There are no STEEL
SHOES AND DIES made excepting under our patent and
sold at this office, or by our authorized agents, though
certain Eastern manufacturers advertise STEEL SHOES
AND DIES which are only cast iron hardened by the
addition of a composition. They will not out-wear two
sets of common iron, though called steel. They are
very brittle and are not capable of being tempered,
suffering from under the hammer like cast iron. Our
STEEL SHOES AND DIES are in use in many of the largest
mills on the Pacific Coast, and all who have tried them
pronounce them cheaper and far superior to iron in
every respect, even at the old price of 20 cents per
pound. Their advantages over iron are cheapness of first
cost, increased crushing capacity, time saved in chang-
ing and in setting tappets, increased value of amalgam
by absence of iron dust and chippings, and a saving of
75 per cent. in freight. It takes 50 days to fill orders
from the manufactory East. Price 16 cents per
pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to
CAST STEEL SHOE & DIE CO., Room 1, Academy Building, S. F.

Tulloch's Automatic Ore Feeders.

Will Feed Wet or Dry Ore
Equally Well.

Will Increase the Quantity from
One to Two Tons Per Day.

SAN FRANCISCO,
Are the only Agents for the sale of
these engines in the Pacific States.

SEND FOR
Descriptive Circular
and Prices.

COOK, RYMES & CO.'S Celebrated Hoisting Engines have been too long in use on the Pacific Coast to require any special recommendation from us. We refer with confidence to any one of the hundreds now in use. We simply state that they still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship for the sake of competing with cheaper engines. For details of sizes send for price list. We desire to call particular attention to our new

MINING HOISTING ENGINES.

(Manufactured by the same parties.)

Which have just been introduced on this Coast. The plans and specifications are the combined efforts of our most successful MINING ENGINEERS, and the result is the most complete

DOUBLE-DRUM HOISTING ENGINE

Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. One of these engines may be seen at work in the Belcher mine, and one in the Ophir, on the Comstock lode, to both of which we refer. We have all sizes of these engines constantly on hand. Ayer's Sarsaparilla, FOR PURIFYING THE BLOOD.

This compound of the
vegetable alteratives, Sarsa-
parilla, Dock, Stillingia and
Mandrake with the Iodides
of Potassium and Iron
makes a most effectual cure
of a series of complaints
which are very prevalent
and afflicting. It purifies
the blood, purges out the
lurking humors in the system, that undermine health
and settle 'into troublesome disorders. Eruptions of
the skin are the appearance on the surface of humors
that should be expelled from the blood. Internal de-
rangements are the determination of these same humors
to some internal organ, or organs, whose action they
derange, and whose substance they disease and destroy.
AYER'S SARSAPARILLA expels these humors from the
blood. When they are gone, the disorders they produce
disappear, such as Ulcerations of the Liver, Stomach,
Kidneys, Lungs, Eruptions and Eruptive Diseases of the
Skin, St. Anthony's Fire, Rose or Erysipelas, Pimples,
Pustules, Blotches, Boils, Tumors, Tetter and Salt
Rheum, Scald Head, Ringworm, Ulcers and Sores,
Rheumatism, Neuralgia, Pain in the Bones, Side and
Head, Female Weakness, Sterility, Leucorrhoea arising
from internal ulceration and uterine disease, Dropsy,
Dyspepsia, Emaciation and General Debility. With
their departure health returns.

Number 24.

Improved Vacuum Pump and Air Compressor.

The simple form of pump herewith illustrated may be used either as an air compressor which is capable of producing an enormous blast at a trifling cost of power, or as a pump for raising water. By producing a vacuum in one of its receivers, and compressing air into the other, both of the above capabilities may be utilized simultaneously—that is, a bellows can be had at one end of the machine and a water pump at the other at the same time. Also, a bellows can be had at each end, or a water pump can be had at each end at the same time, as may be desired.

The whole machine is constructed of metal. The coiled tube, axle and receivers, of a solid metal and of the fluid metal mercury, which flows inside the coiled tube; hence its durability. A, is a spiral tube coiled about, and the ends of which are in communication with the hollow axial shaft, B. C, C, are hollow supports for the latter, and, at the same time, supply conduits, the water passing therefrom into shaft, B, by the inlet valves at D. E, are the exhaust valves, and at F is a partition which divides the shaft, B, into two compartments, so that through its axis there is no communication between the ends of the coiled tube, A. A portion of the coil is filled with mercury, as indicated by the broken away section on the right, the height of the column of mercury being any height desired greater than twenty-eight inches, so as to overbalance atmospheric pressure. One column twenty-eight inches in height compresses one atmosphere. Two twenty-eight inches in height compress two atmospheres and so on. Every atmosphere compressed gives a pressure of fifteen pounds to the square inch.

When the coil is turned by the action of the belt pulley or by hand, in the direction of the arrow, the mercury flowing along the spiral tube from one end to the other will create a vacuum in its rear, while compressing the air before it. In so doing, it will draw water or air through the valve, D, at one end of the shaft, and expel the air before it from the valve, E, at the opposite extremity. If the motion be reversed when the mercury has traversed the length of coil, A, the same takes place with the other pair of valves, while of those first affected, the inlet valve now closes and the outlet valve opens. A moment's inspection of the diagram will show that a continuous suction and exhaust is thus maintained.

If the positions of the inlet and outlet valves be changed, the valves, E, being inlet, and the valves and D, outlet, the apparatus may be used as an air compressor, of which the tubes, C, may be conduits to the reservoir. And a tube may lead from reservoir (not shown in engraving) to furnace or forge. Other tubes than those of C may be used as conduits to the reservoir if desired. In either such cases, valves, E, which, as represented, open outside the shaft, would open inwardly, while the valves, D, now opening inside the shaft, would open into the reservoirs. Water may be raised thirty-three feet. The amount of compression obtained is dependent upon the height and the weight of the mercury column in the tube, and the diameter of the tube. If the coiled tube be fifteen feet in diameter, the air will be compressed at least six times.

The diameter of the tube, the diameter of the coil and the number of coils may be increased as desired. The receivers may be made of any desired size, and the reservoir into which the receivers may discharge themselves may be of any given size, and also the pipes leading from the reservoir to furnace or forge. Attention is particularly called to the small quantity of power necessary to rotate this machine. The mercury and atmosphere being on a balance when a column of mercury only twenty-eight inches in height is used, it is evident that the friction on the journals above has to be overcome (the friction of the mercury and air inside the tube being merely nominal,) in order to raise water and compress the air one time. By increasing the height of the column of mercury the friction on the journals is increased, but it is to be remembered that the power obtained is also greatly increased in

the air compressed. By a small amount of power expended, a great blast can be had. The uses of this machine are many. Besides those mentioned, it may be used for ventilating mines or steamships.

Patented November 24th, 1874. The inventor desires to sell rights or an entire patent. For further particulars address the patentee, Daniel L. Cameron, at Madison station, Madison county, Mississippi.

New Process of Refining Base Bullion.

We have received an addition to our collection of subjects appertaining to metallurgy, in the shape of two little silver bricks, and four bottles containing silver in its various forms and crystallized sulphate of copper (bluestone). These articles are to illustrate the new process of refining base bullion, for which F. H. Bonfield, assayer at the Swiss-American Bank, has

Lead.

[Written for the Press by HENRY G. HANES.]

Metallic lead has a bluish gray color. It is usually tarnished, in which case it has no luster, but when freshly cut shows a surface highly metallic and brilliant. It is a soft metal, very malleable, easily fusible, and volatile at a white heat. It is scarcely acted on by hydrochloric acid or dilute sulphuric acid; but moderately dilute nitric acid dissolves it, more readily if heat is applied.

The presence of lead in any substance containing it may with certainty and ease be determined by heating the sample on a piece of well burned willow charcoal, in one portion of which—nearest the flame—a small cavity or depression has been made, in which the assay

Carbonate of soda produces a white precipitate of basic carbonate of lead, when added in solution to the solution of any lead salt. This precipitate is not soluble in excess of the precipitant nor in cyanide of potassium.

Hydrochloric acid or the soluble chlorides produce in solutions of the lead salts, if concentrated, a heavy precipitate of chloride of lead, which is soluble in a large quantity of warm water.

Sulphuric acid and sulphates throw down from lead solutions a heavy precipitate of sulphate of lead, which is nearly insoluble in water and dilute acids, but dissolves readily in solution of citrate of ammonia.

Chromate of potassa when added to solution containing lead throws down a beautiful yellow precipitate of chromate of lead, which dissolves in potassa, but which is nearly insoluble in nitric acid.

It should be understood that the above reagents are in solution, and are to be added in every case to solutions of substances containing lead.

Lead occurs in nature in a variety of forms, but most of the metal furnished to commerce is from galena or sulphuret of lead. Native lead is reported as occurring in globules at Alston Moor, and at the mines near Caribagena, Spain, but never in sufficient quantity to work, or even to furnish specimens for the cabinet of the mineralogist.

Galena, the most abundant ore of lead, has a metallic luster. Its color and streak are pure lead gray. When broken it is still oblique in form, even when reduced to the finest powder. It always contains silver and sometimes selenium, zinc, cadmium, manganese, gold, antimony, copper and iron. Even platinum is said to be found in galena in France.

It is a mistake to suppose that any external appearance indicates the quantity of silver in a sample of galena.

There is a variety of galena which is called supersulphuretted lead. The excess of sulphur results from the decomposition of a portion of the galena, setting the sulphur free.

There are several minerals which resemble galena, and may easily be mistaken for it. The most common is micaceous iron, a variety of hematite. The resemblance of this mineral to galena is sometimes so striking as to deceive the inexperienced. It may, however, be distinguished by the following tests: When heated on charcoal it gives off no odor of sulphur, nor can it be fused before the blow-pipe. No metallic beads are formed when carbonate of soda is added. After strong heating it becomes red, and on cooling is found to be attractable by the magnet.

Galena in Missouri and Illinois has been extensively worked. The largest deposits in the world are in the Western States, and that ore is there found associated with limestone, blende, carbonate and sulphate of lead, pyrites, and often an ore of copper and cobalt.

The lead region of Wisconsin comprises sixty-two townships, eight in Iowa, ten in Illinois, being eighty-seven miles in diameter, from east to west, and fifty-four miles from north to south. Throughout this region there is scarcely a square mile in which traces of lead may not be found. From a single spot not exceeding fifty yards square, three million pounds of ore have been raised, and in one of the townships two men have raised 18,000 pounds in a day. The mines of the upper Mississippi afford about 760,000 pigs annually, and those of Missouri about 150,000 pigs.

In 1874 the production of lead in California more than doubled, while in the same year that of England decreased 17,000 tons.

For making white lead Eastern corrodors prefer the Missouri lead to any other.

To give the reader some idea of the production of lead in the United States, the following statistics for the year 1874 have been compiled:

	TONS.		TONS.
Missouri.....	15,000	Chicago.....	2,200
California.....	8,000		
New York.....			46,500
Newark.....	6,500		
Philadelphia.....			
Iowa.....		Imported.....	18,000
Illinois.....	5,600	U. S. Sales.....	4,000
Wisconsin.....			
Omaha.....	5,800		68,500
Salt Lake.....	3,500		

In 1874 the Union Pacific railroad carried East 3,500 tons refined lead and 15,000 tons blillion, by which is meant lead carrying more or less of the precious metals.

AIR COMPRESSOR AND PUMP.

recently obtained a patent through the MINING AND SCIENTIFIC PRESS Patent Agency.

No. 1 of the specimens is the bullion as it ordinarily comes from an assay office in the shape of a bar, and is stamped silver, 410 fine, and has a value per ounce of \$0.53.

No. 2 is the metal as above prepared by the patent process and granulated.

No. 3 is the granulation after oxidation.

No. 4 is the metal deprived of its baseness, ready for fusion into pure bars, or ultimate parting, should the original alloy have contained gold.

No. 5 is the extracted copper in the shape of sulphate (bluestone).

No. 6 is a neat little bar obtained by this process, having a fineness of 993 in silver and .002 in gold, and a value per ounce of \$1.32.

The process which these samples are intended to illustrate is eminently simple and economical, and necessitates no actual waste of acid, as is the case with all other processes of humid refining. As the pure metals are never dissolved there is no danger of loss by breakage, etc.; and, should necessity require, they can be collected and utilized at very short notice.

The advantages of using this new method of concentration at the mine, where much sulphate of copper is constantly used, and where freight in bullion embraces both value and weight, are too manifest to need enlarging upon. The new process is a valuable addition to economic metallurgy.

MINING PROPERTY FOR SALE.—The attention of capitalists and miners is called to the advertisement of the Nevada mill and mine, situated on Deer creek, Nevada City, Cal.

may be placed, a little carbonate of soda added and the flame of an oil lamp or large candle turned upon it by means of the mouth blow-pipe. The direction of the flame at first should be downwards until the assay begins to melt, after which it should be blown softly and nearly horizontally across the charcoal. If lead is present in the assay a coating will form on the charcoal which is lemon yellow when hot, and sulphur yellow when cold. Other volatile substances which may be present will also form coatings, but they will be distinct, and at distances more remote from the assay, nor will they be the same color. Zinc, like lead, gives a yellow coating, which to the inexperienced might lead to mistakes, but if the charcoal is allowed to cool the zinc coating will become white, by which reaction it may be distinguished.

The following are the reagents used in the determination of lead in the wet way, and the reactions which occur:

Hydrosulphuric acid or sulphide of ammonium added to solutions of lead salts gives black precipitates of sulphide of lead which are not soluble in cold dilute acids, alkalies, alkaline sulphides or cyanide of potassium, but the precipitate may be decomposed by boiling nitric acid. The acid must be dilute or a part of the lead will be changed to the sulphate and remain insoluble.

Soda, potassa and ammonia throw down basic salts of lead in the form of white precipitates which are insoluble in ammonia. The exception is solution of acetate of lead, from which pure ammonia (free from carbonate) does not immediately produce a precipitate, a soluble triacetate of lead being formed.

CORRESPONDENCE.

Geological Formations.

There appears in the Press of May 15th an interesting article under the caption "Geological Formations—Quartzite," by Mr. William Teal, of Bingham, U. T., in which he sententiously asks, "What is quartzite?"

The query is a relevant one at the present juncture, seeing that its proper constituents are so little understood, notwithstanding the increased and increasing spread of geological information. The subject is one that admits of a wide range of discussion, because there are no two miners of this coast who probably would be found agreeing in their estimate regarding the nature of quartzite. Some define it as belonging to the order of sandstones, and where composed of pure quartz, sandy particles, as a species of silicious sandstone, which has been at some remote period in the earth's history "firmly consolidated" by the action of great heat, the same as crystallization has been produced in other rocky substances.

Quartz.

We know, is pure silica, of which there are many varieties, differing in form and color, and easily distinguished from all the other minerals by its hardness, infusibility, insolubility, and entire absence of cleavage. Quartz is also granular, but this is not one of the characteristics of the variety of quartzite most commonly met with in the mining districts of Nevada. The massive or solid and vitreous structure are the distinctive features of the kind that is most frequently encountered in this State, though one occasionally meets with a laminated vein or belt, but this structure is found more often at and above the outcrop wherever it rises to any great height in vertical stratifications above the surrounding formation. There are many of the varieties of this rock that are regarded as of igneous origin, while none of them can be said to be, in the strict sense of the word, as belonging to the metamorphic family of rocks.

Quartzite

Is not, that I am aware of, usually considered as a metalliferous bearing rock, and is not, as far as my experience has extended, the chief ingredient or constituent of the geological formation of any of the mining districts of Eastern Nevada. It is, however, often seen running in immense belts, ranging from a few feet to one hundred feet or more in thickness, and rising to a great altitude in huge, irregular shaped masses above the outline of the hills. It is, however, associated with many of our most valuable mines, in the character of either the foot or hanging wall—chiefly the former. Such is the case at Reveille in this county, and such too, I am informed, is the case at Pioche, in the Raymond & Ely and other mines. At Eureka it is entirely non-metalliferous, limestone being the prevailing formation, though a quartzite gangue is often found in place with the ore, but this peculiarity is noticeable only wherever the lode is broken or at fault, or wherever the mineral is poor. Here lime and porphyry are the chief rocks, though the former is the actual geological formation. The G mine has a silicious lime hanging wall, and a porphyry foot wall. The latter is also the hanging wall to the Gila mine at Reveille, while the foot wall is a semi-greenish and semi-vitreous quartzite, which at the apex of the lode has a standing or shelving dip to the east. Below this point it extends smooth and unbroken, while the porphyry of the foot wall is largely impregnated next the ore with talc, manganese and the red oxide of lead and iron. The quartzite belt is, as I said above, over or about one hundred feet thick and has a longitudinal course of several miles, or from north to south terminations of the district, which embraces a space of eight by four miles. The porphyry dikes run aside by side, and is distinguished by its bold projections as the other. While the lime formation runs parallel to both at the east and west sides.

Geological Formation

Does, of course, afford some index to the practical or experienced miner, whereby he is nearly always enabled to arrive at a just or partially just opinion of the mineral attributes of the section of country over which his peregrinations may sometimes extend in his search after the mineral wealth which nature has scattered with no niggard hand throughout the vast area of Nevada.

There are, however, no two districts alike in any respect, so that no parallels can be constructed where there are no common conditions found to exist. The order of venous formation also differs in different districts, and in some instances I have found the mines of the same district to differ just as widely, and this too with regard to the proper method of developing them. There are also many embossments caused in metallic mining by the displacement of lodes. These occurrences are most frequent in limestone formations, and from a variety of causes known to the trained miner and skillful mineralogist. Experimental mining can alone determine the structures of lodes by tracing them in their various stages of development,

from their incipient conditions to their fullest expansions, and is also the only sure method of measuring the quantity and value of their ores. These things are, of course, facts that are within the knowledge of every experienced, intelligent miner. But to turn from this subject for the present, I will give a glance at the state of our mineral resources at

Tybo.

The past delightful weather has been very generally taken advantage of by prospectors and others. In consequence there have been very many promising discoveries made in this and adjoining sections within the last two months. The ore is of the milling kind and quite rich. The chief locations are worked by T. J. Bell & Co., Wagner & Rosenthal and Garrett & Co., the two former parties to the east at entrance of canon, and the former in the hills to the west of the

Two G Mine

In which some valuable lode deposits of very fine argentiferous ore have been lately brought to light. I have on former occasions given accurate descriptions of this fine property, and therefore I need now only say that its value and permanence are no longer matters of doubt. The former was established long since, but recent explorations have shown more largely than heretofore that the latter attribute is also placed beyond suspicion.

The Mill

Is progressing towards completion, though it will be a while yet before the music of its twenty stamps will greet our expectant ears. When it does, we will exhibit some evidences of our capability to add to the metallic stream that is beginning to flow oceanwards from this section of Nevada.

A twenty-stamp mill and a twenty-five-ton furnace will do some execution in the reduction here. It is also expected that we are soon to have another company in here, negotiations being now, it is said, pending with some San Francisco parties for the sale and transfer of some of our mines.

Reveille

District, twenty-eight miles southeast of here, of which I wrote some time ago, is at present attracting well merited attention. The Gila is proving the accuracy of my former statements, and it is not yet more than in the infancy of its greatness. Rarely has there been turned out by any mine in the State, in so short a time, a larger quantity of more uniformly rich ore than there has been by this mine since it was opened last February. Much of the ore being extracted has given assay values ranging from \$200 to \$7,000 per ton. It pulps at the mill \$300, and this without being sorted. The mill is a two-stamp dry crusher, and has turned out \$55,000 in bright bullion bars from the lot to the 24th instant, and the remaining six or seven days will result in about \$16,000 more, thus aggregating about \$71,000 for the month's run, while the whole expenses will not be more than \$10,000, thus leaving a clear surplus of \$61,000 to go to dividend fund. There is about \$16,000 or \$17,000 shipped hence by Wells-Fargo each week to New York in hullion. The

"West Side"

Is the name of a new discovery made some six months ago, and its name indicates, to the west of the Gila on the mountain side overlooking and easily accessible from the valley. There is a five-stamp mill and excellent water privileges go with this mine, and all have been recently purchased by J. M. English and J. B. McGee of the Gila, the former the president of the Gila and the latter a director and large owner in some mine, and manager of the Tybo Consolidated mining company, of here. The West Side promises to become equally as valuable as the Gila, its ore, of which there is an abundance in eight, assaying \$300 to \$600 per ton.

J. D. P.

Tybo, Nye county, Nevada, May 26th.

AN OREGON GOLD BAR.—The *Weekly Oregonian* says:—One of the largest and consequently most valuable gold bricks ever brought to this city was on exhibition yesterday at the store of Millard & Van Schuyver, on Front street. The brick was brought down from Baker City, having been taken from the Virtue lode, near that place. This huge chunk of precious metal was the result of seventeen days' run by the Virtue mining company, which will serve to indicate the extreme richness of the lode. Pause, gentle reader, and ponder while you read. This brick weighs thirty-five pounds avoirdupois, or 505 14-100 ounces Troy weight. Its fineness is 903, and its value \$9,455.29. In size it is but a fraction smaller than an ordinary clay brick. It was kept under a glass case, and during the day was the center of attraction. To gaze on that solid mass of auriferous metal was quite enough to make the eye water and the palm itch, of even the most stolid. We were allowed to handle the brick, and never in all our extended reporter's career were we seized with such a desire to slip the hammers in our left vest pocket and run for life. Had it not been for the strict surveillance of the gentleman who was kindly looking after the welfare of the brick, we might possibly never have framed this paragraph. The brick is on its way to the mint at San Francisco, and is soon to be transformed into bright twenty dollar pieces.

AN EXHIBITION of all kinds of railway carriages in use throughout the world is about to be held in New York, with numerous drawings and models of everything appertaining to progression by steam.

Placer Mining in Oregon.

A correspondent of the *Bedrock Democrat* says: With the melting of the snow and the rush of water came busy times, which forced me for a time to discontinue my description of the mines and mineral wealth of Grant county. I will now resume where I left off, namely, at Robinsonville. From there we will pass through a low "saddle" in the mountains to Burnt river; the first mining we find there is at Parkerville, where, for two or three years, not much has been done, though in times past some very rich ground has been worked in this vicinity, with the probability of more of the same kind remaining. Messrs. Parker & Gleason are at work in the main gulch, with pipe and good head of water. Their prospects are good. This place is the over night station of Grier & Kellogg's Canon City line of stages. Mrs. Newton is the landlady, and if you ever stop at her house and fail to get what you would call a No. 1 meal, just give notice in your paper that 7-UP is no judge of grub.

From this place the next camp is Bennett creek and Winterville. Through this section is some of the heaviest deposit of gravel in Oregon, with more or less gold all through it. Further on we find Pine creek, Westfall Basin, Gimlet and Jack Knife, all good gravel deposits, but very short of water. In this region is one of the best chances for capitalists to invest in a ditch that can be found in Eastern Oregon; an extensive supply of water would develop the entire section of Burnt river that now lies idle and unproductive, throwing tens of thousands of dollars in circulation among us, that now reete buried in Mother Earth.

While our capitalists and financiers are working to get the railroad through Eastern Oregon would it not be well for them to look at the chances of increasing the wealth and prosperity of our country in other ways? Now stop! Don't jump on me and go to kicking me for opposing the railroad, for I am in favor of it, and other roads if needed, but I am strongly in favor of pressing the subject of the mineral wealth and resources of our country upon the public, thereby trying to retain our capital and muscle among us instead of sending it on such tips as to South mountain while we are needing it here to add to our prosperity and help build roads and other permanent improvements. Some twelve years' residence and observation in the mineral regions of Eastern Oregon has fully convinced me that this country will yet rank with the best in the amount of precious metal produced—we have it now, all we want is capital and expert prospectors to bring it forth. But, to my description: From Burnt river we will go back to Olive creek. Here, for some seven miles, mining is carried on, not only in the main creek, but also in nearly every gulch coming into it. About twenty companies are at work in the different parts; they are mostly Chinese, though several companies of white men are working and doing well. The principal ones are Messrs. Howard, Chittenden & Co., L. Farmer and Carpenter & Co. The latter took out about a mule load last year, with just as good prospects for the present season. The water privilege on Olive creek is middling; the upper main gulch with its tributaries has a working supply until the last of August, while the lower end of the creek has a head through the entire season. There is still a chance in this section for prospecting and taking up ground.

Douglas County Mines.

The superiority of Douglas county over most of the other counties of the State as an agricultural region has tended to point all our attention in that direction, to the exclusion of the mining interests, which have centered in the vicinity of the "great bonanza." South of us are the Alpine, Benton, Cerro Gordo and Panamint mines, stretched along in one continuous range, and north of us is the great Comstock, all on the eastern slope of the Sierras. Within the bounds of our county are the Bismarck, Pine Nut, the old Sierra claim, besides several others, in all of which the indications are good, and would be extensively prospected if located anywhere in the neighborhood of the Comstock. The Silver Lake company worked their claim to some extent last summer, and here is the result, as taken from the sworn statement of the superintendent, John B. Winters, as given to the County Assessor:

Receipts, exclusive of freights on 225 tons of ore sold Teconia company, Truckee, Cal.,	\$8,000.00
Expense of producing the same,	5,079.23

Which, it will be seen, leaves a profit of \$2,920.77, or about \$13 per ton. This ore was transported a considerable distance on the backs of mules, which was an extraordinary expense.

With rich mines both north and south of us, numerous indications of good mines in our midst, Douglas county certainly merits some attention from mining men; and we feel confident that if only one of the already ledges discovered can be made to become dividend-paying, there will be no difficulty in finding capital to develop others. As stated above, the Winters mine, out in Pine Nut district, has demonstrated that their ore will more than pay for mining and working even in the most expensive manner. When this company get their new furnace in operation and the mine opened so as to work it to the best advantage, we may reasonably expect one good paying mine at least, and through this encouragement the discovery of many others. Let us hope.—*Carson Valley News.*

The Great Union Shaft.

The *Virginia Enterprise* gives the following description of what the combined efforts of the Savage, Hale & Norcross and Chollar-Potosi mines, on the Comstock, are doing and expect to do: During the last days of February a number of men were set at work preparing to grade a railroad track from Tunnel No. 2, between Virginia and Gold Hill, along the rough sides of the hills east of the city to a point three-quarters of a mile almost directly east of the Hale & Norcross works. For two weeks the body of men did little except shovel snow along the line of the intended track. At length work was commenced in Tunnel No. 2. The northern entrance was widened nine feet, and ten new sets of timbers were put in between that point and where the grade ran out. In the meantime work had been extended to different points along the line of the intended grade. Not only was it necessary to grade and lay down a track for the cars, but

A Wagon Road

Must be made the entire length of the grade also. The railroad grade is finished, with trifling exceptions, the ties placed and the iron laid for more than half the entire distance. In fact, this part of the work would have been completed, but that the material on hand which was available for the purpose gave out. There are three fills and four cuts along the line, one of which cuts was made through hard blasting rock and to a depth of eighteen feet. The fills required all the debris from the cuts, with trifling exceptions. The wagon road, which winds around the railroad track, is nearly finished, it only remaining to cut around some of the fills and prepare crossings. Along the line of the railroad are three culverts for letting the surface water pass under the grade. One of them is made of an eight-inch pump-column, the others being of 3x3 plank. To conduct off the surface accumulations around the site of the future works, a culvert has been placed in position which is 2x3 feet in the clear, and amply sufficient for the purpose.

The Site of the Works

Commands a most beautiful view of the city and surrounding country. The city lies like a painted panorama, with Mount Davidson for a background, and lies to be seen at a glance, from the water works on the Divide to the extreme northern limit. To the east, the works will look down on Sutter tunnel shaft No. 4, and out over the beautiful, though rough and rugged, country between them and the Carson river. As to availability, the place for the works which are to be constructed has been selected with much care and forethought, and an admirable situation it is. There is to be an upper and lower grade. The railroad track leads to the upper, where will be located the works proper, wood-pile, etc. The second grade is run in from the bank, thirty-five feet below, and from this the shaft is to be started. A wall five feet in thickness will be built from the lower grade to the upper, and immediately east of the shaft. The landing will be upon the lower grade, which is sufficiently high to enable tracks to be run around to the east side of the hill, so that there is dump room enough there for all time. The ordinary gallow's frame will be dispensed with. The sheaves will be placed upon the wall before mentioned, with just frame enough to hold the pulley wheels in place. These wheels will be of sufficient size to carry the cable over to the center of the shaft.

The Shaft Itself

Is to be of four compartments and will require a "hole in the ground" at least 9x30 and probably 16x30. Three of the compartments will be each 5x6 in the clear, while the fourth or pump shaft will be 5x7 in the clear. These compartments are to be surrounded by timbered 14x14, with 3x12 splines. The entire work of grading and everything ready for the commencement of the shaft will be finished by the middle of next week, and then the shaft will be started. The rocks and dirt, which are loosened up in the same manner as was mentioned in yesterday's article on the California mill, are being removed by eighty men, seven cars, three cars, four wheelbarrows, and at the rate of 3,600 cart loads per day. A double-headed donkey is on the way and the work of sinking will be pushed rapidly forward at the same time that the construction of the works, and the placing of the machinery is going on. The size of the works, etc., has not yet been decided upon, but it will be ample. The blacksmith shop will occupy the lower grade and be south of the shaft.

The Intention is

To make preparations and put in machinery to sink at least a mile, if desirable. To this end nothing will be left undone which can contribute to ultimate success. The machinery will be more ponderous than any yet placed on the Comstock. Everything will be of gigantic proportions, such as will comport with and contribute to the gigantic ends in view. The movements along the line of the Comstock have been with its dip, toward the east, and toward the east everything has gravitated. The wisdom of the combination is patent, in that a leap over intervening obstacles has been made, the ground secured and an abundance of it, and a foundation commenced firmly and of immense proportions and promise. Everything is in keeping with the undertaking, and will be pushed to completion with the same energy and ability which has characterized its early developments. Thus far the grading has been under the supervision of Mr. A. Perrin, foreman of the Chollar-Potosi.

CUTTING GLASS WITHOUT A DIAMOND.—An easy method of breaking glass to any required form is by making a small notch, by means of a file, on the edge of a piece of glass; then make the end of a rod of iron red hot in the fire, apply the hot iron to the notch, and draw it slowly along the surface of the glass, in any direction you please; a crack will be made in the glass and will follow the direction of the iron. Round glass bottles and flaske may be cut in the middle by wrapping round them a worsted thread dipped in spirits of turpentine, and setting it on fire when fastened on the glass.

MINING SHAREHOLDERS' DIRECTORY.

have yet seen. The soapstone is cased in soft granite. The ledge is about three feet in width. Blocks of any desired size can readily be procured. Messrs. Schraak and Robinson are the discoverers, but we are not informed where the deposits are located.

WEST POINT DISTRICT.—A mule train is packing a lot of rich ore from Briggs & Co.'s mine to the crest of North Fork ridge, whence it will be hauled to custom mills. Some 60 tons of ore from the Champion has been hauled to Carlton's mill. It is reported that very favorable developments have been made in the Mina Rica. The Enterprise mill is running pretty steady. The Anderson Flat mine is turning out very rich ore, which is 18 inches wide. The ore is heavily sulphuretted but every particle of it shows free gold. A shaft is being sunk on the Good Faith which will connect with the main tunnel for the double purpose of ventilation and to facilitate stoping. The width of the ore in the Josephine has not been ascertained yet. The ore now being crushed exceeds the expectation of the owners by at least 25 per cent.

CONTRA COSTA.
GOLD AND SILVER MINE.—Contra Costa Gazette, June 5: It is reported that rock containing gold and silver has been found near Lafayette; but, as the assay shows only some \$14 or \$15 per ton value in the rock, it will not be likely to encourage very expensive prospecting unless the mine promises to afford a large body of ore, of which we believe there is no assurance.

EL DORADO.
DITCH PROGRESS.—*Mountain Democrat*, June 5: Operations on the new ditch are progressing.

MINING SUMMARY.

THE following is mostly condensed from journals published in the interior, in proximity to the mines mentioned

California

LIVERMORE COAL MINE.—Livermore Enterprise, June 5: The prospects at the Livermore coal mine are increasing more and more each day as work is pushed ahead. A large winze for the purpose of ventilation, has been sunk, and only a few feet further will be required to connect it with the main shaft. The latter has reached the depth of 300 ft, and the timbering is being done preparatory to running side drifts and stoping. A fine sump remains at the bottom of the main shaft. We expect to report next week the shipment of coal to market.

CALAVERAS.

Tmolus—Good Rock.—Calaveras *Chronicle*, June 5: Thirteen and a half tons of rock taken from the Tmolus mine, in the Jeane Maria district, yielded 59 ounces of amalgam. That is an average of something over \$30 per ton, pretty good considering that the rock was taken from a depth of only about 50 ft. The ore was packed on mules to the mill on the Anstrutia mine to be worked. If a less expensive method of transportation could be devised, or a mill erected on the mine, the Tmolus would prove very remunerative.

LATE VALUABLE DISCOVERIES.—There can be seen at this office samples of pure asbestos and soapstone which are of the finest texture and

Mining Stocks.

The mining stock market this week exhibits rather a falling off in strength than an advance. It was expected that dividend declarations and the opening of the new stock board would perhaps raise prices a little, but these circumstances have failed to do so. There was a lull in Ophir, California and Consolidated Virginia on Wednesday, but this was probably only temporary. There is considerable opposition between the three stock boards now in operation in this city, but it has not seemed to help prices at all. At the session of the "Old Board" on Wednesday, under the regulation increasing the membership from eight to one hundred, Wm. Sharon, J. P. Jones, C. Flood, R. F. Morrow, J. D. Fry, Wm. O'Brien, Alexander Austin, G. M. Pinney, C. Hooker, C. N. Felton and H. H. Scott were elected.

ected to seats, and the remaining nine wi

killed to-day. The usual formality of a new was dispensed with, the Secretary casting vote. Each one of these gentlemen pays \$400 for his place. George M. Pinney is a member of the Exchange, and as there now two in the board who are members of bodies, some action will doubtless be taken the older organization on the matter. The change is indifferent about the subject, will let the old board take the initiatory s Latest dividends and assessments can be by reference to our 'Shareholders' Directors and latest prices of stocks, by referring to stock tables.

NEW INCORPORATIONS.

The following companies have filed certificates of incorporation in the County Clerk's office at San diego:

EAST OPHIR S. M. Co.—June 7th. Location: O county, Nevada. Trustees—Alphous Bull, O. M. Chisler, J. Collins, J. F. Atwill, and H. R. West. Capital, \$100,000,000.

CALIFORNIA RIFLE ASSOCIATION.—June 7th. To encourage rifle practice, to promote a system of firing, drill, and target firing among the National of the State, and to provide a suitable range for the of the members of the Association. Trustees—Chas. J. James, Geo. Henry G. Shaw, John Comb, David Wilder, George Humphrey, Her Burns, E. H. Pardee, Sheldon J. Kellogg, Jr., Jacoby, and John B. Griswold. This corporation no capital stock.

REVENUE M. Co.—June 9th. Location: O county, Idaho. Trustees—A. K. P. Harrison, C. L. Tier, Robert Sherwood, George M. Pinney, and Holcombe. Capital, \$5,000,000.

ORIGINAL GENESSEE M. Co.—June 9th. Location county, Nevada. Trustees—Wm. M. Stewart, Morgan, Louis Aldrich, J. R. Hardenberg and

Mining Stocks.

The mining stock market this week shows rather a falling off in strength than an advance. It was expected that dividend days and the opening of the new stock board would perhaps raise prices a little, but these circumstances have failed to do so. There was a little stir in Ophir, California and Consolidated Virginia on Wednesday, but this was probably only temporary. There is considerable opposition between the three stock boards now in operation in this city, but it has not seemed to help prices at all. At the session of the "Old Board" on Wednesday, under the resolution increasing the membership from eighty to one hundred, Wm. Sharon, J. P. Jones, J. C. Flood, R. F. Morrow, J. D. Fry, W. S. O'Brien, Alexander Austin, G. H. Pinney, R. C. Hooker, C. N. Felton and H. H. Scott were elected to seats, and the remaining nine will be filled to-day. The usual formality of a hallows was dispensed with, the Secretary casting the vote. Each one of these gentlemen pays \$25,000 for his place. George M. Pinney is also a member of the Exchange, and as there now are two in the board who are members of both bodies, some action will doubtless be taken by the older organization on the matter. The Exchange is indifferent about the subject, and will let the old board take the initiatory step. Latest dividends and assessments can be seen by reference to our "Shareholders' Directory," and latest prices of stocks, by referring to our stock tables.

New incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

EAST OPHIDS. M. Co.—June 7th. Location: Store county, Nevada. Trustee—Alphous Bull, (M. Peck). Charles J. Collins, J. F. Atwill, and H. R. West. Capital, \$100,000.

CALIFORNIA REEF ASSOCIATION.—June 7th. Object: To encourage reef practice, to promote a system of fishing and to regulate and direct fishing among the National Guard of the State, and to provide a suitable range for the use of the members of the Association. Trustees—D. V. C. Thompson, James Coey, Henry G. Shaw, John M. Cornb, David Wilder, George Humphrey, Henry Burns, E. M. Pardee, Sheldon J. Kellogg, Jr., Phil J. Jarry, and John B. Griswold. This corporation has each stock \$500.

REVENUE M. Co.—June 9th. Location: Owyhee county, Idaho. Trustees—A. K. P. Harmon, C. L. Wheeler, Robert Sherwood, George M. Pinney, and S. Holcombe. Capital, \$5,000,000.

ORIGINAL GENESSEE M. Co.—June 9th. Location: Lyon county, Nevada. Trustees—Wm. M. Stewart, James Morgan, Louis Aldrich, J. R. Hardenbergh and W. V.

ing very smoothly and satisfactorily. From 1,200 to 1,400 hends are at work, of whom about one-half are white men and one-half Chinamen.

At Wook.—The battery of the Woodside mine, Greenwood, started up last Tuesday, with flattering prospects for a prosperous season. We are assured by competent judges that the sulphurets from the Woodside mine are immensely rich.

MINING ENTERPRISE.—At the St. Louis—formerly known as the Menning—mine, heavy machinery for pumping and hoisting works is being delivered and put in place, with a view to a thorough testing and development of the mine. A splendidly timbered shaft with three compartments is down 90 feet, at which depth there is a large, well defined and widening ledge of fine milling ore, but the flow of water was too great for the small pump and light machinery formerly in use. This mine is principally owned by St. Louis capitalists of enterprise and abundant means. O. P. Johnson, late of Springfield, Missouri, is superintendent, and a brief acquaintance has been sufficient to convince us that he is the right man in the right place, one of those energetic, thorough going business men of whom our mining interests have stood much in need, a man of sound judgment, large information, much shrewdness, and with an unlimited supply of "sand in his craw." Under his management of the St. Louis mine we feel hopeful that our people will learn what they have long been anxious to know, what there is in the quartz of our section at the depths where the mines of other districts have yielded their best pay. We are in no degree fearful as to the ultimate result if Johnson holds his grip and is properly sustained by his company.

FRESNO.

SPECKERMANN QUARTZ MINE.—Fresno *Expositor*, June 2: We understand that Wm. Speckerman has bonded his quartz mine, near Crane valley, to a San Francisco company. The company are to work the mine at their own expense, and give Mr. Speckerman one-fourth of the proceeds. This mine is supposed to be quite valuable. It was discovered some four years ago, and Mr. Speckerman has worked it from time to time with varying success. The quartz is of a decomposed nature and shows considerable gold, but the gold, owing to the presence of some mineral, does not seem to have an affinity for quicksilver. It is generally supposed that with scientific working the ore will pay largely. The company propose to extract the ore by contract.

INYO.

LIDA VALLEY.—Coker. *Inyo Independent*, June 5: Lida is little spoken of, now a days. There never was much blowing about it, but now it seems that we are to take a place among the places more favorably known, as the Lida milling and mining property has been incorporated; capital stock \$3,000,000. Gold Mountain mines have also been incorporated for the same amount. Similar steps have been taken with the Montezuma mines. It is expected that active operations will be commenced by all those companies soon; should this be a reality, this summer may prove to be a lively one. However, those camps do not entirely depend upon those companies.

PANAMINT DISTRICT ITEMS.—Panamint *News*, June 1: In the Kennedy tunnel, in the Wyoming mine, a magnificent development has been made of very high grade ore, assaying from \$114 to \$1,100 per ton. This tunnel is run from the east side in the red mountain. This ledge is certainly wonderful, tracings and openings having been made upon it for a distance of nearly three miles, and there seems to be very little if any diminution either in the class of ore or width of vein. On the north side of Surprise canon we find that the workings in all the mines show a decided improvement in every respect. In the light of recent developments the croakers of Panamint have entirely subsided, and nothing now remains but to put into operation our mills, send out the bullion and prove to the world that the Panamint mines are capable of eclipsing the productions of any other mines on the coast, not excepting the "big bonanzas" of Nevada.

NEVADA.

NEW YORK HILL.—Grass Valley *Union*, June 6: Friday evening the new pump on the New York Hill mine was started up, and the "hand power" force were discharged. The new pump is an eight inch, which is large enough for all the water they expect to find. The specimens are still coming out thick and fast. We saw several fine specimens at the bank yesterday, all of which have been taken out within a day or two.

CINCINNATI HILL.—This well known mine, which has been worked as far back as 1854, but which has remained idle for some time, has begun to show life again. The machinery that used to be on the William Penn mine is now being erected on the shaft, which is 100 feet deep. Forty loads of rock, which it is estimated by experts will yield from \$50 to \$75 per load, have already been taken out, and there is plenty more in sight, which stimulates the owners with renewed confidence.

PITTSBURG MINE.—Splendid specimen rock is now being taken out of this mine. Last Thursday they struck quite a bonanza. The Pittsburg is quite a good piece of property.

OSCEOLA.—This enterprise has again started up and the owners are busily engaged in clearing at the old tunnel, and in repairing their shaft. Already they have taken out some good rock, which is very encouraging to them.

LARIMER'S MILL.—This old mill, which has

crushed out so many tons of rock, is now about to enlarge its capacity, in order to meet the increasing demand, for there are hundreds of tons of rock that now await crushing. The stamps have heretofore been run by water power, but the water seems to be getting scarce, and so to insure a constant operation, some steam machinery that used to be in Eu-reka South has been purchased, and will be used by this mill. The foundation has already been laid and the boilers set, and the rest is being placed in position as rapidly as possible. Ten more stamps will be added. When the water becomes short, the steam will furnish the motive power, and so the precious metal will flow in a ceaseless stream from its batteries.

OMAHA.—We were yesterday shown a specimen that was carelessly picked up from the dump of the Omaha, in which we saw a large amount of free gold and plenty of sulphurets. There are forty loads of rock at the Larimer mill now being put through the stamps, eighty more at the mine awaiting transportation, and before this is crushed they will have enough more ready to swell the number of loads to at least 125. The Omaha company have commenced to erect machinery on their works. They have purchased machinery formerly owned by the Enterprise gravel mining company, who used to operate at Buena Vista. The machinery will be running in about thirty days from date. The Omaha shaft is down 300 feet.

PLACER.

WILL IT PAY?—Placer *Herald*, June 5: This question has often been asked in reference to the enterprise now being prosecuted with so much vigor by the Auburn gravel mining and ditch company. From what we know of the country, and from what we have heard, we had believed it would prove a good investment. From what we have recently seen this belief has been very much strengthened. While on the ground a few days ago, we witnessed the washing of three pans of dirt, taken, as we saw, promiscuously from three places on Grizzly hill. Those three pans yielded, at the very lowest estimate, fifty colors, visible to the naked eye, from the size of a pin-head down. Sections of this hill, we heard an old miner say, would pay \$10 a day to the man with sluices. What, then, will be the result when worked by hydraulic? The company intend to begin washing on this hill, which, though comparatively shallow, is, so far as they know, supposed to be the richest. From this hill they are sanguine of getting out every dollar they have put into the enterprise, and it is but a garden patch compared with the broad field of deep gravel lying before them. These are the indications at present as to whether it will pay. They will, if all goes well, begin washing by the first of July next, and in a month or less from that time we will know more about it.

CHROME.—The work of extracting ore on the Chrome mine has been begun in earnest. It is, we understand, being raised as fast as two four-horse teams can haul it to the station, or at the rate of from eight to ten tons per day.

SONOMA.

LOCAL ITEMS.—Russian River *Flag*, June 3: The second furnace for the California borax company will be finished in about ten days.

The kiln of brick for the furnace of the Great Eastern (Guernville district) will be fired next week.

The Mt. Jackson continues to yield good ore and plenty of it, but the furnace fails to give satisfaction. It will probably soon be re-modeled.

M. S. Bush, superintendent of the Annie Belcher, informs us that that mine will resume work June 20th.

The Harriet, adjoining the Annie Belcher, owned by Jno. Goldthorpe and John Knight, has developed good metal. About 500 tons is now on the dump.

STANISLAUS.

ANOTHER MINING COMPANY FORMED.—Stanislaus *News*, June 4: There was a meeting of those who had subscribed to the formation of the Modesto mining company at this place last Saturday. The meeting was called to order by J. J. Scrivner; J. D. Spencer elected Chairman, and J. J. Scrivner Secretary. A majority of the members being present the company proceeded to perfect a temporary organization, which was done by the election of five directors, consisting of Judie Schell, A. Hawel, J. R. McDonald, Thomas Farrell and J. D. Spencer. On motion, J. W. Houson was elected Treasurer. There are fifty-four members of the company, and all have signed an agreement to pay assessments to the amount of \$100 each, to be used, if deemed necessary, in the location, prospecting and development of mines in this county.

TRINITY.

CINNABAR.—Trinity *Journal*, June 5: James Mullane was in town this week and informs us that everything in the Cinabar district is prospering. Lytle and Hawtack are retorting about 40 tanks of quicksilver per week, having already shipped over 200 tanks. They have been unable to procure tanks enough and are compelled to make troughs from logs, in which to put the quicksilver as it flows from the retorts. In the mine the ore is constantly improving. Mullane is packing out from 7 to 8 tons of concentrated ore per week. H. C. Wilt is working his claim, while Superintendent Dickinson has started a tunnel on the Bonanza mine on the east side of Crow creek.

RIVER MINING.—Seven companies of white men are preparing to work in Trinity river, just above Lewiston, this summer. Many other

places along the river will be worked this season, as the low stage of water is more favorable than ever before and there is little else to do anyway.

COPPER MINE.—Ten or twelve years ago a copper lode was discovered in Trinity Center district, about four miles from the Carr place, and on the opposite side of the river. Several shafts were sunk along the ledge to the depth of 30 or 40 ft, but could not be sunk deeper on account of water. From these shafts rich ore was taken and many large pieces of almost pure copper were found. The locators, finding it impossible to work the lode through shafts, started a tunnel with which they expected to tap the vein 200 ft below the surface, in running a distance of 250 ft. This tunnel was in very hard rock, so hard that not more than one foot a day could be made; expenses were so heavy the owners were compelled to abandon the project after the tunnel was in a distance of 140 ft. Since then nothing has been done at the mine. Recently John Martin, Armentrout, Trotter and others have relocated the lode and tunnel right, and intend to run the tunnel to the ledge. Provision, tools, powder, fuse, etc., have been sent to the mine, and operations will commence at once.

Nevada.

WASHOE DISTRICT.

CONS. VIRGINIA.—Gold Hill *News*, June 3: Daily yield, 600 tons of ore, keeping the mills all running up to their full working capacity. The ore breasts are looking well and yielding the usual amount of good ore. The joint east cross-cut on the 1400-ft level is steadily advancing, not yet having reached the east wall of the ore vein.

OPHIR.—Daily yield, 150 tons of ore. This ore is being mostly extracted from the 1465-ft level. At the depth of 47 ft, perpendicularly below the 1600 ft level, the winze being sunk has been connected with the southwest drift from the east shaft, affording a fine circulation of good air, and greatly aiding the development in that portion of the mine. The bottom of the winze and drift also were in fine ore when the connection was completed.

BULLION.—Cleaning out the old incline below the 800-ft level preparatory to sinking it on down to connect with the north drift on the 1700 ft level, for prospecting and air purposes, has been commenced, and is making favorable progress. The body of quartz developed on the 800-ft level still continues of a very encouraging character.

ORIGINAL GOLD HILL.—The ore body developed by the cross-cuts from the south drift opens out finely, and everything will soon be ready for ore extraction and milling.

CHOLLAR-POTOSI.—Daily yield of ore 65 tons, the assay value of which is \$28 per ton. Sinking the main incline is making fair progress.

BELOZER.—Daily yield of the mine, up to this morning, 500 tons of ore. The ore breasts throughout are looking well.

BALTIMORE AND AMERICAN FLAT.—The cross drifts on the 754-ft level have developed some fine bodies of quartz and low grade ore, but nothing that will yet pay for milling. The cross drifts on the 850 ft level have not yet developed any considerable body of quartz ore.

CALIFORNIA.—The completion of the air winze from the 1400 ft level to connect with the upraise from cross-cut No. 3, has greatly improved the air circulation in the south portion of the mine, adding speed and comfort to all the prospecting now being done in that section.

COSMOPOLITAN.—The Hope mill is kept steadily running at the rate of 25 tons per day on ore from the stopes above the tunnel level.

JUSTICE.—The cross-cuts from the main drift, at the 400-ft level, from the south mine, as well as the winzes below it, show a good amount of ore developed and indicate a large ore body.

BEST & BELOZER.—The Burleigh drills in the face of the main south drift on the 1700-ft level are advancing at the rate of about 15 ft per week, the rock in the face still being of a very tough, hard character.

CROWN POINT.—Daily yield, between 500 and 600 tons of ore. There is no change to report of either the appearance or yield of the ore breasts.

SENATOR.—Some very fine looking quartz has been met with in the drift this week, giving encouraging assays. The machinery is all right and operating finely.

JACOB LITTLE CONS.—The good ore developed by the main west drift, as well as by the cross drifts, is accumulating on the dump, ready for milling as soon as required.

ELY DISTRICT.

AMERICAN FLAG.—A letter of the 2d says: Ore in the third level still looks encouraging, but the ore body is lessening in size.

MEADOW VALLEY.—The weekly letter of June 1st says: The east drift, 1200-ft level, has been advanced 8 ft, making its total length 583 ft. The drift being run to the west, following the ore streak from the rise on the 1200-ft level, has been extended 10 ft; the ore seam has dwindled to one-half inch in width, but is very regular, giving reasons to hope that it will again make its appearance with greater width. The west rise, which is being carried up from the east drift, has attained a distance of 13 ft, the top showing very hard quartzite formation, with only a very small seam of ore to show the continuation of the fissure. Winze No. 2, which was being sunk from the east drift, when it reached a depth of 30 ft met such a heavy body of water that they were compelled to suspend

operations. The cross-cut being run south from the summit shaft, on the 1200-ft level, is again being advanced. On this dump there are 130 tons of ore, and about 6 tons are being daily extracted.

RAYMOND & ELY.—Bullion shipped June 9th, \$11,041. The weekly letter of the 31st says: The main shaft is down 50 ft below the 11th level. Water rushed in very rapidly after letting off a blast in the bottom of the shaft, on the 30th, but it was lowered at the date of writing 20 ft, leaving 5 ft to be drained. The 10th level drift has been advanced 23 ft, making its total length 1042 ft, and the face shows well in ore. The ninth level drift has been advanced 25 ft, making its total length 1349 ft; no pay ore in the face. Winze is down 49 ft, in bottom of which there is about one foot of fair ore. The 8th level has been advanced 5 ft, with no pay ore in the face; 35 to 40 tons of ore is being extracted daily.

ALPS.—The mine is daily improving and a large amount of bullion will be shipped this month.

Arizona.

SILVER BELT.—Arizona *Miner*, May 28: This company has about fifty tons of ore procured in sinking a shaft seventy feet on the ledge. This ore varies more in richness than in the character of the metal it carries. The ores, so far as can be judged without analysis, are sulphurets of silver in combination with galena and a trace of antimony. Yet there are seams all through the rock and little pockets filled with what appears to be chloride of lead, but upon collecting and washing it is found to contain considerable quantities of metallic silver. A small furnace with a fan blower, to be run by horsepower, is erected, and lined with a fire clay found in the mine and mixed with quartz tailings.

The Isabella lode belonging to the Big Bug company, near Prescott, is not a large lode or extraordinarily rich. It is well opened on the surface for nearly 100 feet in all, besides having a shaft down 25 feet in one place, at the bottom of which the vein is about three feet wide. A ditch has been brought on the lode and several tons of pay ore ground sliced out and piled up ready to be sent down on a tramway to the creek, where the battery from the Big Bug mill will be set up, and run by water from the ditch to crush it. In sluicing out the ore now on hand, they saved from \$12 to \$18 per day in free gold to the hand, which is sufficient evidence of the value of vein matter, aside from what may be in the rock itself. The Isabella runs parallel with the Eugenia, and dips into the mountain toward the other, is of the same character of ore, and as the Eugenia is a perpendicular ledge, it is believed that at a depth of several hundred feet, that they come together and form one ledge, or in other words, that the Eugenia is the ledge and the Isabella a spur. They have crushed some seven or eight thousand tons from the Eugenia, with good results, but it is quite inaccessible on account of its great elevation, and if it can be reached through the Isabella it would greatly facilitate its working and render it much more profitable.

Montana.

MEAGHER COUNTY MINES.—Helena *Independent*, May 27: The miners in Cave gulch are all busily engaged upon their mines, have plenty of water and are in fine spirits. No clean-ups of any consequence will be made until the 1st of July. The indications are that the mines will pay better this season than for the past four years.

In all the small gulches near Cave there is water, and the miners are taking out good pay.

Several companies are working in Oregon gulch and all are doing well.

The Drain company in Magpie are still at work prospecting their ground.

Two bed-rock flumes are being put down in Hell Gate canon, and we understand have struck some rich prospects.

Two companies are working on Avalanohé with good results.

The ditch being constructed by Marshall and Sutton is progressing favorably. The excavating has been completed, and the lumber for the flumes is now being sawed and hauled upon the ground. When completed it will put the waters of Trout creek upon Gruell's bar, which is said to be very rich.

Utah.

BOULDER SPRINGS DISTRICT.—Salt Lake *Tribune*, June 5: Boulder Springs is the name of a new mining district opened on the 28th of last month, in Cedar valley, three miles from Boulder Springs, Tooele county. The Ophir laws were adopted, with an amendment requiring \$25 work in 30 days, \$25 in six months, and \$50 in 12 months. M. L. Cont was elected recorder. Four locations have been made—the Rambling Boy, Mountain Chief, Juniper and Boulder Springs. The former has a shaft down 8 ft, showing a 5 ft vein of ore, assaying 65 per cent. lead and \$18 silver. The formation is quartzite and spar. Timber and water are plentiful throughout the district, and the country is easy of access. The Utah Western railway is surveyed through the district, and when completed, will make the facilities for the shipment of ore very complete.

A valuable discovery of silver bearing rock has been made within 10 miles of the city, in the past few days. Samples left at the *Tribune* office assay 84 ounces silver, 50 per cent. lead and \$5 in gold. The owners of this new location are H. Cushing, T. G. M. Smith and F. D. Clift.

The Mouth of the Mississippi.

Much attention is being turned at this time to the engineering works just undertaken under the direction of Captain J. L. Eads, for the improvement of the mouth of the Mississippi. The importance of such a work to the great valley of that river can hardly be overestimated.

The Difficulties to be Overcome.

The Delta of the Mississippi is formed of narrow strips of land, mostly low-lying banks, through which the river winds until it makes its exit to the Gulf by a number of narrow passages. In some of these channels previous attempts have been made to deepen by dredging, with but partial success, however, as a single flood has been known to carry down sufficient sediment to fill them to their original depth; and the current, besides, emptying into the open water at the mouth, speedily left at that point bars of blue clay, surmountable only by light draft ships. Captain Eads proposes an entirely different plan—that which is known as the jetty system—which has succeeded most admirably at the mouths of many European rivers. Captain E. will operate at the South pass, one of the three principal mouths. The bar at this mouth is covered with seven feet of water at its shallowest point, is about two and a half miles long, and increasing at the rate of about 100 feet a year. The channel is about 730 feet wide, and Captain E. proposes to gradually narrow it, working from both sides until the increased force of the current will scour out the channel instead of continuing its present deposit of mud.

How it is to be Done.

The work is to be done in the following manner: Willow twigs are to be bound into bundles, called in engineering parlance "fascines." These fascines, say eight or ten feet in length, and as many inches in diameter, are put together in the form of a raft, like timber logs, towed to the required spot, and loaded with stones until they sink. This process is repeated with successive rafts until a continuous foundation is laid the entire length of the proposed line of jetties. The first or foundation rafts will be from seventy-five to 200 feet in width, according to the depth of water where they are sunk, the deepest water requiring the widest rafts. As soon as the foundation is completed in this manner, another line of willow rafts is sunk on top of these already down, and so on until the surface of the water is reached, each line of rafts being narrower than the one below it, until the topmost line will not be more than ten feet across.

By this means a channel is created with sloping sides. The water gradually fills up the interstices between the twigs with sand and sediment and in the course of a few years the structure becomes as solid as a wall, being in fact a submarine levee. It will readily be seen that an almost incalculable quantity of willow twigs will be required to construct these two long lines of jetties the whole length of the South Pass, and the work of cutting and preparing them will furnish employment to a great many men.

Some piling will have to be done at the head of the pass in order to provide for the proper regulation of the volume of water in the new channel at various stages of the river.

Captain Eads regards the construction of the jetties in the South pass as more feasible and easy of accomplishment than the work would be in the Southwest pass, on account of the large amount of sand that is carried down in the former, and which will pack and solidify the jetties much quicker than the muddier deposit of the other; though the commercial advantage is in favor of the Southwest pass.

The work is to be done at the expense of the national government, at a total cost of \$5,500,000, when a permanent depth of thirty feet has been secured. Partial payments are to be made as the work progresses, as follows: \$500,000 when a depth of twenty feet is secured, and \$500,000 additional for every two feet until thirty feet depth of water has been secured.

The Ultimate Success

Of Captain Eads in the completion of the jetty is not now questioned by any save his enemies. The known energy and engineering skill of the man are sufficient to insure the success of any enterprise he undertakes, and he has not engaged in this project without first satisfying himself, beyond doubt, of the practicability of the plan upon which he will proceed to open the mouth of the Mississippi. Captain Eads has found an abundance of capital to aid him in the work until the first payment comes due from government. Capitalists seem to have no limited confidence in his judgment as an engineer. The work is one of national importance.

FAULTS OF CONSTRUCTION IN BATTERY CONTACT.—Emile Girouard points out that one great obstacle in the way of our obtaining cheap electricity lies in the defect of the contact. The rivets which connect the zinc to the carbon are often ill made, and after having been in use for some time, they are corroded all round, and the oxidation prevents the contact from being perfect. The current, consequently, is unable to pass, unless the tension is considerable enough to overcome the bad conductivity of the oxide. The author proposes to obviate these defects by having all connections, etc., made of platinum.

Free clay rubbed on the hands will remove the unpleasant odor of chloride of lime.

Toughened Glass.

One of the most interesting and important improvements in glass making reported for many years is that recently patented by Bastie of Paris, which consists of a "toughening" process, applied to ordinary glass, after it has already been placed in the desired shape. No change of shape can be made subsequent to the "toughening." The following report of some experiments with this glass recently made by Messrs. Abel Rey & Bros., of London, will be found very interesting:

The toughened glass is in no way distinguishable by the eye from common glass. Its transparency is in no way impaired by the toughening process, and colored glasses, whether opaque or transparent, retain without change their original appearance. Various specimens were shown to us both of transparent and colored glass, such as window glass, plate glass, watch glasses, lamp glasses, glass plates and dishes of various kinds, and a number of other objects. These were thrown about the room in the most reckless manner without fracture of any of them taking place, though many of them were thrown as high as the ceiling and allowed to fall upon the floor. This, however, did not appear to be an adequate test, and so we proceeded to test the glass with a hammer.

A piece of common window glass toughened was laid by a flat upon a bench with one corner overhanging about two inches, and this overhanging part was struck by us many times with a common carpenter's hammer without being cracked or broken, the hammer rebounding from the glass in much the same way as if it were a sheet of iron. Finally, by an energetic stroke, the glass was broken. But the fracture was not like that of common glass at all. The piece broken off was crumbled into crystalline fragments resembling crystalline white sugar of large grain, and these fragments were not splintered, but a box full of them could be stirred up by the hand without the skin being broken. The piece of glass remaining under the hand on the table was not starred or cracked in the usual manner, but a network of cracks was spread uniformly over its whole surface, giving it the appearance of lace, and on being handled this portion also disintegrated itself into crystalline fragments all of about the same size.

The texture of the glass is completely altered by the toughening process. A diamond will no longer cut it. But the glass may be ground down like common glass on the wheel, and even when half the thickness is thus removed, the diamond will fail as before to make any impression in separating it, showing that the change in the glass has gone to the center. And not only can the glass withstand mechanical violence, but it is no longer liable to be cracked by alternations of heat and cold. Toughened lamp glasses will last forever, and saucepans, tea kettles, and other articles of a similar kind used in domestic economy may now be made of glass without much risk of injury. Cups and saucers, plates and dishes, jugs and basins, and other articles heretofore made of china or earthenware may now be made of glass, either transparent or opaque as may be desired, or partly one and partly the other, and if the glass is toughened the articles will be little liable to fracture. In every department of the art the new material will find important applications, and taken altogether the invention is probably the most valuable that the present generation has witnessed.

The Process of Toughening.

But what is the process, it will be asked, by which this great improvement has been wrought? Its simplicity is marvellous. It consists in heating the glass up to near the softening point, and then plunging it in a bath of oil or grease. There is nothing in the process, therefore, which will materially enhance the cost of the manufacture, but glass will now be used for numerous purposes for which it has heretofore been inadmissible. Gas and water pipes may now be formed of glass, as well as sulphuric acid chambers, cisterns, and stills, imitation marble chimney pieces, and numerous other objects. No material is more elegant than glass. The objection to it heretofore has been its brittleness, and this objection has now been done away.

The following extract is copied from the inventor's patent paper: "As the fragility of glass results from the weakness of the cohesion of its molecules, it may be expected that by forcing the molecules closer together, and rendering the mass more compact, the strength and solidity of the material should be increased. I have found that this can be effected by compression even when applied to the material in a fluid or soft condition. I have therefore applied to glass a system of tempering such as is usually applied to steel, and I will now describe the process and apparatus for this purpose.

"Fused glass dropped into water becomes greatly contracted, but, being shapeless, only objects of curiosity can be produced in this way. The sudden cooling in the water puts the glass into a state of unstable equilibrium in its constitution, so that the least shock causes it to break up, as in the case of Prince Rupert's drops. My object is to invert this result, to diminish or even to remove the extreme fragility of glass by tempering it by immersion in a liquid. In attaining this object two essential conditions have to be determined: First, the point at which glass can be tempered without

being put out of shape. I have found this to be when it is just at the heat where softness or malleability begins, the molecules being then capable of closing suddenly together, condensing the material when it is plunged in a liquid, at a considerably lower temperature. Also glass, when it is thin, may be tempered at red heat even before becoming soft; secondly, the liquid to be employed for the immersion of the glass, being such as can be heated much higher than water without boiling. For this purpose I find oils and grease, wax, resin, and tar or pitch suitable. Having settled these conditions, I have devised the process or practical method of operating, and suitable furnaces and apparatus, which will hereafter be described.

"In carrying out the process it is necessary that the glass to be tempered should be raised to a very high temperature; the hotter it is the less is the risk of breaking the glass, and the greater is the shrinkage or condensation. Hence the advantage and often the necessity of heating the glass to the point of softening, which is attended by the difficulties that glass in the soft condition gets readily out of shape, so that it must be plunged almost without touching it, and that in plunging the hot glass into a heated combustible liquid the latter is apt to take fire, and cannot easily be extinguished, so that time and material are lost. These difficulties are overcome by placing the tempering bath in immediate communication with the heating oven, and covering it so as to prevent access of air. The oven being charged with the articles to be tempered, these are pushed or caused to slide into the adjoining bath without handling them, and the liquid of the bath having no supply of external air is not liable to inflame."

Color in Decoration.

Decoration is the art of adorning the objects we use, and the houses we occupy. To accomplish this successfully, the art should ever be accompanied by its handmaidens—knowledge and taste. In the study of any art it is necessary to understand thoroughly the rudiments of the first principles of the art, and to teach these is one of the great objects of technical education. To decorate an object appropriately, it is necessary to consider the material of which it is made. From the beginning we must work on certain principles. Let the construction be evident, and if carving or inlaid ornament be introduced, let it form a feature with the construction, and not overlay or disguise it.

A proper disposition of well proportioned forms is the first consideration. With respect to color decoration as applied to the adornment of dwellings, it should be the ambition of every man to have his home clean, comfortable and tasteful; and a knowledge of the rudiments of the science—for it is a science—must be useful to every man. Color gives life to form; its variations, properly harmonized, delight the eye, and have a powerful influence on the mind when treated with the skill which a careful and well trained study of the art enable us to exercise.

To study properly the subject of color, we must begin with the consideration of light. When the rays of white light are intercepted or dispersed, color is produced. Familiar to all is the glorious rainbow, which, as Thomson has told us is

Born of the shower, and colored by the sun.

The rays of light emitted through a prism give out a series of brilliant colors known as the solar spectrum; and the relations of the colors thus produced form the rudimentary principles which regulate the science of color. With regard to harmony, how to bring together various colors in such proportions as to produce an agreeable effect, bright red and bright green, bright blue and bright orange, could not be used together in masses without much modification. To combine various modulations of color so that they may mingle together and form an harmonious whole, demands careful study, practice, and taste. We cannot too strongly urge upon those who seek to improve themselves in decorative art, to study carefully natural flowers and foliage, both for gracefulness of form and for harmony and richness of color. In decoration, it might be laid down as a principle that one color should dominate. In the majority of cases the most perfect and beautiful harmony is produced by employing neutralized hues of color of the larger masses, and then giving freshness, cheerfulness and beauty to the whole by the introduction, in small masses, of the primary or secondary colors that might form the proper equivalents to the prevailing color. It should always be remembered that the eye is never satisfied with any arrangement of color unless all the primaries are present in some shape or other. In carrying out decoration, it will be found that all colors have two kinds of harmony—that of analogy, or sympathy, and that of contrast. In churches, large halls, or public buildings of importance, it is necessary to consider very carefully the peculiar circumstances of each of them before designing the decoration or arranging the colors. Architects should be made to indicate the use of color in a building on which they have bestowed much careful study and labor. Judicious and well-designed arrangements of color should add to the architectural effect. By the use of the principal constructive features of a building should be emphasized or clearly expressed; and the whole, avoiding confusion, should present a combination of symmetry of form and harmony of color.—Ez.

Extensive Mining and Ditch Enterprise.

The *Piscer Herald* says: We have often had occasion to refer to the enterprise now being vigorously carried on by the Auburn gravel mining and ditch company, but never at sufficient length to give the reader a clear idea of the full extent of the work. The company is composed of men who, after satisfying themselves by extensive prospecting of the rich character of some extensive gravel deposits, a few miles northeast of Auburn, filed articles of incorporation, and at once began the work of bringing water in, a work on which they are now engaged, and a work which will lead to the development of these deposits and contribute liberally to increase the gold yield of the county and country for years to come. The enterprise is certainly a giant one. Many have been well aware of the rich character of these deposits, but when they come to consider the immense amount of labor and capital necessary to bring water in for successfully working them, the charms of the rich pan prospect faded by comparison, and they turned away in despair. To overcome the obstacles that presented themselves, was left for the capital and iron determination of this company, composed of only six or eight stirring men, and it is but fair to wish them the brightest returns, that present flattering invitations give reason to expect.

Bear river ditch runs at present, as it were, at the very foot of the hills which this company propose to wash down. Before any washing could be done, therefore, it became necessary first to secure a sufficient amount of water from Bear river ditch, and second, to bring that water in on a plane high enough to afford pressure for hydraulicking. The first difficulty was overcome by satisfactory arrangements between them and the owner of the ditch, to the effect that on and after the first of July next they are to take 500 inches of water. In order to obtain the desired raise, it was necessary to take the water out of Bear river ditch, about five miles above the claims. On this work they are now mostly engaged. The water is to be run the first three and one-fourth miles in an open ditch, exclusive of one stretch of flume of 1,100 feet. This ditch is five feet wide on top, three feet on the bottom, and two and one-half feet deep, cut in the solid ground. Seventy-five men are now engaged on it, who have 680 rods completed, and will have the entire job finished by the middle of June. From the end of the ditch the water is to be conducted through canons and over hills for about two miles in heavy iron pipe, twenty-two inches in diameter. This pipe is to be buried beneath the ground, the ditch two and one-half feet wide and three feet deep, for the reception of which, is now completed.

The contract for furnishing the pipe was let to Currier, of the San Francisco boiler works. Already 8,000 feet of the pipe is on the ground, 1,800 feet riveted together and covered up, and the whole job is being driven to completion as fast as two teams can haul the pipes out and distribute it along the line, and twenty-two boiler makers and twenty laborers can put it down, rivet it together and tar the joints. On the line of this pipe there are two depressions through which the pipe forms inverted siphons, the deepest of which is some 220 feet. The water, as conducted from the terminus of the ditch through this pipe, will be delivered at the claims under a pressure of 238 feet, exclusive of seventy feet allowed for friction. The company will begin washing on what is known as Grizzly hill, a small mound of comparatively shallow gravel. They are now running a tunnel six feet wide and seven feet high, to the center of this hill, at which point they will commence piping, running the dirt through the tunnel in a ground sluice, which latter will be in all some 1,500 feet long, constructed with all the modern improvements for saving gold. A number of teams are now engaged hauling lumber for the flume and sluices, work on which will be begun by a drove of carpenters this next week. The company is determined to commence washing by the first of July, and though there is yet much work to be done, at the way they are rushing things there is no doubt but all will be ready. As anon as they get started at Grizzly hill, they will put their force at work in laying a branch pipe to Tunnel hill, about 1,500 feet southeast of the former, which contains not less than eighty acres of very deep gravel. Besides this the company owns Westchester hill, about one-half mile west of Grizzly hill, which embraces about 160 acres of gravel known to be at least 150 feet deep, and Pine hill and Summit hill, which latter will be after consideration. This company owns in all about 500 acres of mining ground, in one body, enough to keep them mining for at least twenty years. This ground they purchased of J. B. Hobson, last winter, mention of which was made at the time. All their works are under the superintendence of Mr. Hobson, who is an interested party, and who orifies things ahead with an energy and skill becoming the magnitude of the work he is engaged in.

SOLNER FOR BRAZING STEEL.—The following solder will braise steel, and may be found very useful in case of a valve, stem or other light portion breaking when it is important that the engine should continue work for some time longer: Silver, 19 parts; copper, 1 part; brass, 2 parts. If practicable, charcoal dust should be strewn over the melted metal of the crucible.

USEFUL INFORMATION.

Filing Saws.

The grand secret of putting any saw in the best possible cutting order, consists in filing the teeth at a given angle to cut rapidly and of a uniform length, so that the points will all touch a straight edged rule, without showing a variation of a hundredth part of an inch. Besides this, there should be just enough set in the teeth to cut a kerf as narrow as it can be made, and at the same time allow the blade to work freely without pinching. On the contrary, the kerf must not be so wide as to permit the blade to rattle when in motion. The very points of the teeth do the cutting. If one tooth is a twentieth of an inch longer than two or three on each side of it, the long tooth will be required to do so much more cutting than it should, that the sawing cannot be done well. Hence the saw goes jumping along, working hard and cutting slowly. If one tooth is longer than those on either side of it, the short ones do not cut, although the points may be sharp. When putting a cross-cut saw in order, it will pay well to dress the points with an old file, and afterwards sharpen them with a fine whetstone. Much mechanical skill is requisite to put a saw in prime order. One careless thrust with a file will shorten the point of a tooth so much that it will be utterly useless, so far as cutting is concerned. The teeth should be set with much care, and the filing should be done with great accuracy. If the teeth are uneven at the points, a large flat file should be secured to a block of wood in such a manner that the very points only may be jointed, so that the cutting edge of the same may be in a complete line or circle. Every tooth should cut a little as the saw is worked. The teeth of a handsaw for all sorts of work, should be filed fleaming, or at an angle on the front edge, while the back edges may be filed fleaming or square across the blade.—*Ex.*

THE STRENGTH OF WOOD AND THE EFFICIENCY OF THE AXE.—In a recent volume of the annals of the Forest Academy, at Mariabrunn, near Vienna, Prof. W. F. Exner gives a novel and highly instructive analysis of the elasticity and strength of wood, its resistance to splitting, and the use of the wedge, the axe, etc. The importance of these matters he shows to be very great, because great industries depend upon the applicability of certain kinds of wood. Having deduced a few simple formulae to express the strength of woods and the power of the wedge, he develops a formula for the force with which an axe is handled, and shows what curve should be given to the face or cheek of the axe, in order to secure, under certain conditions, the least waste of power. By these formulae he is able to demonstrate that the splitting efficiency of the best axes made in Vienna, Prague and America, are to each other as 13.3 and 9.2, and 4.9, respectively; and applying his formulae to the elaborate experiments of Nordliugen, he is able to deduce the absolute ease with which various woods can be split.

TO PREVENT SPLITTING OF HANDLES.—All carpenters know how soon the butt end of chisels split, when daily exposed to the blow of a mallet or hammer, and we are indebted to one of our subscribers, Mr. W. Esmark, a stair builder, in Brooklyn, N. Y., for a remedy to prevent this, which he kindly requested us to publish. It consists simply in sawing or cutting off the round end of the handle, so as to make it flat and to attach by a few small nails on the top of it, two round disks of sole leather, so that the end becomes similar to the heel of a boot. The two thicknesses of leather will prevent all further splitting, and if in the course of time they expand and overlap the wood of the handle, they are simply trimmed off all around.

TEMPERING STEEL.—In hardening and tempering steel, a clean charcoal, anthracite, or coked bituminous coal fire is required; such as is fit for taking a welding heat on iron is entirely unfit for hardening purposes. The sulphur contained in the coal combines with the steel to form sulphuret of iron, and ruins its texture.

In hardening and tempering cast steel, the following is the golden rule:

"Hammer to a polish,
Harden at a blood red,
Temper to a straw color."

TO WORK HARD STEEL.—If steel is rather hard under the hammer when heated to the proper cherry-red, it may be covered with salt and hammered to about the shape desired. More softness can then be obtained, if required to give a further finish to the shape, by sprinkling it with a mixture of salt, blue vitriol, sal ammoniac, saltpeter and alum, made cherry-red again, and sprinkled with this mixture and hammered into shape. This process may be repeated until entirely finished. When ready the steel is hardened in a solution of the same mixture. This method is recommended by Mr. W. R. Lake.

TO OIL A BELT.—The best mode of oiling a belt is to take it from the pulleys and immerse it in a warm solution of tallow and oil; after allowing it to remain a few minutes the belt should be immersed in water heated to 100° F., and instantly removed. This will drive the oil and tallow all in, and at the same time properly temper the leather.

Hair Springs.

Perhaps the most provoking incident that occurs to the practical watchmaker in a watch repair shop, is the "putting in" of a new hair spring. If he attempts to take the wire from a spool, he has no test by which he can equivoque the weight of the balance rim.

Whether the repairer coils the wire or buys the untempered spring, the result is the same. We have touched upon this subject as, in our duty as journalists we are bound to furnish all the information that may fall within our ken. Recently there has been imported an article that will make the watch repairer glad. We refer to the graduated springs of Emanuel's, who is gaining a considerable trade from the fact of his manufacturing a reliable hair spring that watchmakers can depend upon being of excellent service—tempered and assorted from numbers 2 to 20, both in size and tension; consequently, in selecting a spring from any one of these papers, the workman has not the great disadvantage against him, that he must at the close of a series of experiments throw out the results of his labor and substitute another spring. The whole trade should be thankful that such a good article as a first class tempered hair spring has been introduced, for their own comfort and profit must be greatly enhanced.—*The Watchmaker.*

TO PRESERVE POSTS.—The *American Chemist* says that a Western farmer discovered many years ago that wood could be made to last longer than iron in the ground. Time and weather, he says, seems to have no effect on it. The posts can be prepared for less than two cents apiece. This is the recipe: Take boiled linseed oil and stir into it pulverized charcoal to the consistency of putty. Put a coat of this over the timber, and, he adds, there is not a man who will live to see it rot.

CASE HARDENING SMALL IRON WORK.—A simple method of case hardening small cast iron work is to make a mixture of equal parts of pulverized prussiate of potash, saltpeter and sal ammoniac. The articles must be heated to a dull red, then rolled in this powder, and afterward plunged in a bath of four ounces of sal ammoniac and two ounces of prussiate of potash dissolved in a gallon of water.

GOOD HEALTH.

Contaminated Drinking Water and Typhoid Fever.

Dr. Haegler of Basle, gives the details of an outbreak of typhoid fever in the village of Lausen, near Basle, where the ordinary conditions that have been said to govern the disease, such as the character of the subsoil and subsoil water, were extremely unfavorable for the development of the disease, and where, in fact, for a long time there had been no typhoid. In August fifty-seven cases occurred within a space of nine days, and in all the houses of the village except six, while these six drew their water supply from a source entirely different from the others. On investigation it was learned that two months previously there had been cases of typhoid in a farm house not far from the village, and that the dejections of the patients had been thrown into a little stream running through the yard, or into a ditch communicating with it; this stream joined the larger one that supplied the village. Other excrementitious matter had also been thrown upon dung heaps, from which a drain led to the same stream. Dr. Haegler concluded from these facts:

1. That the epidemic of typhoid fever in this instance was the result of drinking water contaminated with the dejections of typhoid patients.

2. He believes that typhoid fever depends upon a specific poison obtained from typhoid patients. Other putrid matter and decomposing organic substances, and at any rate, the filth of privies and dung heaps with which the typhoid dejections may be mingled, cannot produce the disease, since this instance shows that the drinking water of the town had been fouled by these substances for years without producing any bad result.

3. The ordinary situation of contaminated water by its passage through the ground, will not disinfest the water or furnish any protection against the action of the typhoid poison.—*Jour. of Applied Chemistry.*

TO PREVENT COUGHING.—The best method of easing a cough is to resist it with all the force of will possible, until the accumulation of phlegm is greater, then there is something to cough against, and it comes up very much easier and with half the coughing. A great deal of hacking and heaving and coughing in invalids is purely nervous, or the result of mere habit, as is shown by the frequency with which it occurs while the patient is thinking about it, and its comparative rarity when he is so much engaged that there is no time to think, or when the attention is impelled in another direction.

WHEN TO TAKE A WARM BATH.—A warm bath should be taken at night just before retiring, and if the system is weak the bed and sleeping room should be warm to prevent taking cold. Very few persons can take a warm bath in the daytime and go out into the air and attend to ordinary business without much peril.

Acidity.

Acidity of stomach always arises from that organ not being able to digest, to work up the food eaten, to extract the nutriment which it contains, hence two results: First, the food decays, that is, rots, becomes sour and generates a sour gas, which is belched up, causing a burning or raw sensation, located apparently at the little hollow at the bottom of the neck, or in that vicinity. Sometimes an acid fluid is generated and is belched up, and is so very sour occasionally as to take the skin off some parts of the throat, mouth or lips. Second, the food not being properly worked up, does not give out its nourishment, the system is not fed, and consequently becomes weak, the circulation becomes feeble, the feet grow habitually cold; the person is easily chilled, and dreads going out of doors; is happiest when hugging the fire, and takes cold so easily that the expression is frequently used, "the least thing in the world gives me a cold." When such a condition is reached these colds are so frequently repeated that before one is cured another comes, and there is a perpetual cough which the most unintelligent know is the certain harbinger, the forerunner of consumption of the lungs.

When persons are troubled with indigestion, and one of its effects, acidity, the advice given in nearly all cases is to take something to correct the acidity, such as cream of tartar, soda, saleratus, the ley of wood ashes, and other alkalies. These things correct the acidity, but the stomach gets no power of a better digestion, the effects as far as sensation is concerned are removed, but the system continues to be improperly nourished; the man grows thinner and weaker; and with wasting of flesh and strength, there is diminished power of circulation; the person becomes chilly, colds are taken from slight causes and at diminishing intervals, and before he knows it he has an annoying, hacking cough, which too often ends in a wasting, fatal disease.

When acidity follows eating, it is because there has been an error in the quantity or quality of the food eaten; the stomach could not manage it, could not perform the work imposed upon it. The true remedy is to eat less and less at each meal, until no acidity is perceptible, or to change the quality of the food; and in a short time the stomach, not being overtasked, gets time to rest, to recuperate, to get strong; then it digests more food and digests it better, with the inevitable result of a more vigorous constitution, more power of endurance, more strength of body and greater elasticity of mind, more happiness and a spirit and energy to grapple with life's duties, which makes existence a pleasure.—*Hall's Journal of Health.*

LIME WATER FOR BURNS.—A correspondent writes that the readiest and most useful remedy for scalds and burns is an embrocation of lime water and linseed oil. These simple agents combined form a thick, cream-like substance, which effectually excludes the air from the injured parts; and allays the inflammation almost instantly. He mentions a case where a child fell backward into a bath tub of boiling water, and was nearly flayed from her neck to below her hips. Her agonies were indescribable; but her clothing being gently removed, and the lime and oil preparation thickly spread over the injured surface, she was sound asleep in five minutes. Subsequently the parts were carefully washed with warm milk and water three times a day, the oil dressing renewed, and the little patient rapidly recovered. Though all the scalded skin came off, she did not have a scar. This remedy leaves no hard coat to dry on the sores, but softens the parts, and aids nature to repair the injury in the readiest and most expeditious manner. This remedy may be procured in the drug stores; but if not there accessible take a lump of quicklime in water, and, as soon as the water is clear, mix it with the oil and shake it well. If the case is urgent, use boiling water over the lime, and it will become clear in five minutes.

ONIONS FOR SLEEPLESSNESS.—I now venture to suggest a new but simple remedy for want of sleep. Opiates in any form, even the *Liquor opii sedat* and chlorodyne will leave traces of their influence the next morning. I therefore prescribe for myself, and have frequently done so for others—onions, simply common onions raw, but Spanish onions stewed will do. Everybody knows the taste of onions; this is due to a peculiar essential oil contained in this most valuable and healthy root. This oil has, I am sure, soporific powers. In my own case they never fail. If I am pressed with work, and feel that I shall not sleep, I eat two or three small onions, and the effect is magical. Onions are also excellent things to eat when exposed to intense cold. Mr. Paraby, Trontdale Fishery, Keswick, informs me that when collecting salmon and trout eggs in the winter, he finds that common raw onions enable him and his men to bear the ice and cold of the semi-frozen water much better than beer, etc. The Arctic expedition, just now about to start, should therefore take a good stock of onions. Finally, if a person cannot sleep, it is because the blood is in the brain and not in the stomach; the remedy, therefore, is obvious; call the blood down from the brain to the stomach. This is to be done by eating a biscuit, a hard-boiled egg, a bit of bread and cheese, or something. Follow this up with a glass of wine or milk, or even water, and you will fall asleep, and will, we trust, bless the name of Frank Buckland.—*Land and Water.*

DOMESTIC ECONOMY.

Dinner.

Dinner, both in the nature and quantity of its components, must be regulated by the constitution and judgment of individuals, who, however, bearing in mind a constant and consistent discrimination with respect to aliments, should be careful to study the peculiarities of their constitution and digestive powers, and to adapt their diet to them. We may, however, very well add, that those who are chiefly employed in mental occupation, and not exposed to much bodily labor, require less animal food than such as are in the continual exercise of corporeal strength, and should consequently avoid excess in that particular; with this exception, that an hysterical or hypochondriac tendency seems to require animal food, which, however, should be freely joined with the vegetable. We may here also properly remark that no error is in this country more common or more dangerous than the neglect of bread. This valuable edible is the safest and most nutritious of vegetable aliments, and the best corrector of animal food. By its plentiful use alone, the bad consequences of an excess of the latter may be obviated. The tables of the French are supplied as freely with animal food as those of the English, yet that people, by a greater use of bread and dried acid fruits, prevent the ill effects of a heavier diet, and preserve a cheerful buoyancy of spirits, to which the generality of the phlegmatic islanders are strangers. The English, therefore, who are so much devoted to animal food, should particularly moderate its effects by a liberal use of bread and other vegetable matter, since vegetable food is necessary to secure, not only health, but long life. In infancy and youth we should be confined mostly to it. In manhood and the decline of life we should more freely use animal nourishment; and in old age, we should return to the vegetable. Vegetables and milk, indeed, are strong antidotes to soury, and putrid and inflammatory fevers; nay, in the former disease, milk alone will frequently do more good than any other remedy.—*Ex.*

MINCED VEAL WITH POACHED EGGS.—Take some remnants of roast or boiled veal, trim off all brown parts, and mince very finely. Fry a chopped shallot in plenty of butter; when it is a light straw color, add a large pinch of flour and a little stock; then the minced meat with chopped parsley, pepper, salt and nutmeg, to taste; mix well; add more stock, if necessary, and let the mince gradually get hot by the side of the fire. When quite hot stir into it off the fire the yolk of an egg and the juice of a lemon to be strained and beaten up together. Serve with pipets of bread fried in butter, round it, and three or four poached eggs on top.

NUN'S PIE.—Soak one pound of salt codfish in cold water for two hours; put it on the fire to boil, adding a small red pepper and the skin of an orange. Boil eight good sized potatoes, and, when ready to mash, pick up the codfish, squeeze over it the juice of one orange, and mesh all together; add a large lump of butter, put the mixture in a bake-tin, and cover with bread crumbs; scatter a few small lumps of butter over it, and cover the whole with milk. Bake one hour. If well made, it will be as light as a meringue pie, and, altogether, enjoyable.

APPLE PUFFS.—Mix a quarter of a pound of butter with a quart of sifted flour, two eggs and a spoonful of salt; half teaspoonful soda, dissolved in a little cold water; moisten it with cold water so that you can just roll it out easily; roll as thin as possible; cut into cakes; put three of them together, sprinkle flour between each one; lay on the top thin slices tart apples; sprinkle sugar and a little nutmeg over them; press the edges well together, fry in sufficient hot lard to cover them. When of a light brown take up carefully.

DELMONICO PUDDING.—One quart of milk; three even tablespoonfuls of corn starch, dissolved in cold milk; the yolks of five eggs; six tablespoonfuls of sugar. Boil three or four minutes; pour in a pudding dish and bake half an hour, or perhaps less time will do if the oven is hot. Beat the whites of the eggs with six tablespoonfuls of sugar; put it over the top and return the pudding to the oven till it is a nice light brown. No sauce. Nice for Sundays, as it can be made the day before.

TO FRY CHICKEN.—The best fried chickens are thus prepared: The chickens are killed, scalded, picked and washed out cleanly in water, then quartered and thrown into boiling lard. In a few minutes they are done brown, and are then removed and served up hot and dry, not put into grease again. In this way the fowl "is tender as chicken," and is a great delicacy. If you don't believe it, try it, and if you do believe it, try it.

ARCTOA LINIMENT.—Add to one pint of sweet oil two tablespoonfuls of tincture of arnica; good for wounds, stiff joints, rheumatism and all injuries.

VINEGAR WHISKY.—Take of milk one pint, vinegar half an ounce; boil for a few minutes, and separate the curd. Excellent for the sick.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Improved Vacuum
Pump and Air Compressor; Lead, 377. Salvador
Mines; Selling Mines; Notes at the Foundries; Com-
mencement Day in Berkeley; Academy of Sciences;
Notices of Recent Patents, 384. Short Lectures on
Patents; Tea; Hints on the Washoe Process, 385.

Patents and Inventions.—General News Items, 388.

ILLUSTRATIONS.—Air Compressor and Pump,
377. Tea Plantation—Fust-Yama in the Back-
Ground; Sifting and Sorting Tea Leaves, 385.

CORRESPONDENCE.—Geological Formations,
378.

SCIENTIFIC PROGRESS.—The Mechanical
Cause of Ebullition; Substitute for a Microscope;
Hydrogenized Iron; A Curious Magnet, 379.

MECHANICAL PROGRESS.—To Preserve Iron
From Rust; A Remarkable Lifeboat; Mechanical
Triumphs; Smelting Metals in Crucibles; Extraor-
dinary Velocity of a Projectile; The Best Steam
Boiler; Casting Metals; Invention Wanted—\$5,000
Reward Offered; Cutting Glass Without a Dia-
mond, 379.

MINING STOCK MARKET.—Sales at the San
Francisco Stock Board; Notices of Assessments;
Meetings and Dividends; Review of the Stock Mar-
ket for the Week, 390.

MINING SUMMARY from the various counties
in California, Nevada, Montana, Arizona and Utah,
380-1.

DOMESTIC ECONOMY.—Dinner; Minced Veal
with Poached Eggs; Nut's Pie; Apple Puffs; Del-
monico Pudding; To Fry Chicken; Arnica Liniment;
Vinegar Whisky, 383.

GOD HEALTH.—Contaminated Drinking Water
and Typhoid Fever; Acidity; To Prevent Coughing;
Lime Water for Burns; Onions for Sleeplessness,
383.

USEFUL INFORMATION.—Filing Saws; The
Strength of Wood and the Efficiency of the Axe; To
Prevent Splitting of Handles; Tempering Steel; To
Work Hard Steel; To Gil a Belt Hair Springs; To
Preserve Potte; Case Hardening Small Iron Work,
383.

MISCELLANEOUS.—An Oregon Gold Bar; Placer
Mining in Oregon; Douglas County Mines; The Great
Union Shaft, 378. The Month of the Mississippi;
Faults of Construction in Battery Contact; Tough-
ened Glasses; Color in Decoration; Extensive Mining
and Ditch Enterprise; Solder for Brazing Steel, 382.

Salvador Mines.

Mr. John F. Flint, U. S. Consul at Salvador,
Central America, arrived in this city this week
on the *Colima*. While here he intends calling
the attention of mining men to the mining in-
terests of that section of country, which are as
yet entirely undeveloped. The ore in the mines
there is mainly silver, containing some gold,
and averages from \$40 per ton up into the
thousands. Encouragement is given to fore-
igners to work the mines, and labor is cheap,
miners being hired at fifty cents per day, the
common rate of labor being thirty cents. Sev-
eral of the mines are now being worked, one
by a French company on a good scale. This
company shipped through the custom house to
Swansea last year ore valued at \$150,000.
There are no reduction works in the country,
arrastras only being used. One of the mines
—Loma Larga—is worked down to 130 feet,
and operations have been suspended for want
of capital. This mine has yielded over \$500,
000. It belongs to General Gonzales, Presi-
dent of the State of San Salvador. He has in-
vested some \$100,000 in the mine, including
purchase money and money expended in pur-
chasing engine and pump and clearing the mine
of water. He now wants other parties to help
procure the necessary machinery to work the
mine. The large amount of money yielded by
the mine was taken out with little outlay from
comparatively shallow workings. Mr. Flint
promises to give us some further items with
relation to the mining interests of Salvador. He
thinks there is a good field there for men pos-
sessing the requisite experience and capital.

The new combination shaft, on the Com-
stock, described in another column has been
commenced. This shaft will have four com-
partments, three of which will be five by six
feet in size, and will be used for hoisting. The
other will be six by seven feet in size and will
be used for the pump shaft.

The usual amount of prospecting is being
vigorously carried forward in the old upper
levels of the Sierra Nevada mine, without yet
developing any paying or valuable ore bodies.

Selling Mines.

How many meritorious and valuable mines
sitting idle in California and Nevada to-day
for want of capital to work them? The question
is as difficult to answer, no doubt, as the ques-
tion, "How shall these mines be made profitable
without capital?" The most difficult thing in
most cases is to get capitalists to make the first
move toward even examining the mine, or
sending their experts to it. Many of our readers
will remember very vividly the weeks and
months they have spent in San Francisco try-
ing to get the attention of capitalists. They
will recollect how very difficult it was even to
get these people to examine the rock or map,
or even listen to them at all. In despair of
doing so, most miners are compelled to defer
to some hangers-on of California street who
may be fortunate enough to have the ear of a
rich mining man. This person will keep the
owner of the mine dancing attendance on him
for several weeks to impress him with his im-
portance. Then perhaps he will drop the mat-
ter, or else offer hundreds where thousands
were asked. Sick and tired of capitalists and
capital, the disgusted owner, thinking perhaps
that he wants neither at his mine after his ex-
perience, either sells for what he can get or re-
turns home a sadder and wiser man.

This is not the experience of one alone but
of many, and these circumstances have created
in our midst a class of men whose sole oc-
cupation is "placering mines"—either organizing
companies or selling to capitalists. These men
are more accessible than capitalists until they
finally become capitalists themselves. Their
business is to find out the location of a mine in
which some work has been done, and then in-
corporate a company and put the stock in the
market, or if the mine is really a good one it is
sold to the heavy mining men who "incorpo-
rate" it themselves. They expect, of course,
to make a good thing out of both buyer and
seller, and with a man of experience and good
connection, the business is a profitable one.

It will of course be seen that this class of
men, even without the slightest mining or
metallurgical knowledge, exercise a powerful
influence on our mining interests. Their
knowledge of the ins and outs of mining as
carried on at California street; their acquaint-
ance with the men who advance money on
mining property; the skill they display in get-
ting mines cheap and selling them high; and
the fact that it is difficult to negotiate mines
without their assistance, all combine to make
their influence felt. To the hard-working, in-
dependent miners nothing is more disagreeable
than hanging about asking favors of men
richer than they, so they turn their property
over to these men to do what they can with it.

While these people are, under present sys-
tem, useful to both miner and capitalist, it is
unfortunate that they cannot be done away
with and the seller and buyer brought together
without the intervention of a middleman, who
invests no labor and no money. "Mining
Bureaus" are not successful and probably
never will be, for it is almost impossible to
keep their managers incorruptible. There is
so much chance for "jobs" in a business of
this kind that few people have confidence in
the promises of corporations or individuals
who make a business of this sort of thing. If
it were possible to bring miners and capitalists
together, many good mines now lying idle
would be worked with profit to owners and
miners. Until, however, some better system
than that in vogue is adopted, it is probable
that many of these mines will continue in their
present semi-abandoned position for want of
the requisite capital to put them in working
order.

Notes at the Foundries.

At the machine shop of Hawkins & Cantell
they are building some new style percussion
rock drills after a pattern invented by L. W. Coe,
of this city. It is called the California drill.
The working parts are few and the valve and
rotary motion are very simple and novel. One
of these drills has been at work in the Consol-
idated Virginia mine since February, and has
operated so well that a number are now being
made for the same mine. Three of them are
to be tried at the New Almaden quicksilver
mine next week. The drills are made in two
sizes, 3½ inch diameter and 5-foot stroke, and
2½ inch by 3½ stroke. We shall shortly give
a detailed description of this new drill.

At the Etna Iron Works (Pendegast &
Smith) they are making quartz mill machinery
for a 20-stamp mill to go to Idaho. The mill
is a dry crusher. A new style roasting furnace
is also being made to go with the mill.

They are also building water jackets for
smelting furnaces at the Kohler Reduction
Works, and castings for same. The retort
pots, fronts, etc., for John Reynolds' new
chemical works, on the San Bruno road, are
also being made at these iron works. The
proprietors of these works are under con-
tract to furnish acid for the new bullion refin-
ing works at the mint.

They are also building several house fronts,
one for Belden block, another for the new
extension of the Humboldt Savings Bank, and
another for a large building to be erected in
Santa Barbara. A good deal of jobbing is also
being done at this foundry.

Commencement Day in Berkeley.

The Commencement exercises of the Univer-
sity of California were held yesterday at the
Assembly room of the University, at Berkeley.
The room was elegantly decorated for the oc-
casion and was crowded with a very select au-
dience from this city and elsewhere. The ex-
ercises, under the direction of President Le
Conte, passed off very pleasantly to all, and
creditably to the young gentlemen graduates.

The salutatory was pronounced in Latin by
Alexander D. D'Ancona, of San Francisco, and
the valedictory by Dwight B. Huntley, of
Oakland. There were three orations. A philo-
sophical oration (Lord Bacon), by Isaac T.
Hinton, of San Francisco; an English oration
(Arotic Explorations), by Frank B. Sutton, of
San Francisco, and a classical oration (A Pas-
sage in Sophocles), by Josiah Royce, of Oak-
land.

The degree of Bachelor of Arts was conferred
upon the following candidates: Charles F.
Boardman, Chesley K. Bonestell, Joseph G.
Brown, Alexander D. D'Ancona, Frank Deering,
Arthur F. Low, Josiah Royce and W.
Turkington. Bachelor of Philosophy—John F.
Alexander, Leonidas S. Burchard, H. J. W.
Dam, John O. Wyatt, Frederick V. Hollman,
H. O. Lang, F. S. Sutton, John W. Rice, W.
P. Gummer, Isaac T. Hinton, Dwight B.
Huntley, George W. Pierce, R. H. Robertson,
H. H. Webb, W. R. Windsor.

The degree of Master of Arts was conferred
upon John L. Beard, of the class of '68, and
George W. Reed and John M. Whitworth, of
the class of '73.

The literary exercises were concluded by a
very appropriate and thoughtful address by
President Le Conte.

We understand that ninety-three applications
had been made for admission to the new class up
to Monday last. This number of applications
at so early a day betokens the entry of a very
large class for the present year.

Academy of Sciences.

A regular semi-monthly meeting of the Cali-
fornia Academy of Sciences was held on Mon-
day evening last. Frank Soule, Jr., Professor
of Astronomy and Civil Engineering, and S.
B. Christie, Assistant in College of Chemistry,
University of California, were elected resident
members.

The following donations to the museum were
received and described by the Curator: Specimens
of volcanic formation from Colima, donated
by J. Roedel chestnut or ash-wood found
imbedded in quartz rock, 230 feet below the
surface, at Palisade station, on the Central
Pacific railroad, Elko county, Nevada, and do-
nated by A. J. Dennison.

The Swiss Consul presented a handsome
broeze medallion of Agassiz, the naturalist,
made in Neuchatel, Switzerland, the native
place of him whom the design commemorates,
by F. Laundry. On the face of the medallion
is a well executed bust of Agassiz, on the reverse
an olive leaf, within which is read *Homo In-
genio Laboris, Scientia Praestantissimo*.

Mr. Amos Bowman briefly described a stone
pestle and mortar which he presented, and es-
timated that he would give a more detailed descrip-
tion shortly. The specimens are important in
a geological point of view.

The Secretary read a paper by Henry Ed-
wards, on *Vanessa Californica*, being No. 13 of
a series on Pacific Coast Lepidoptera, written
by Mr. Edwards.

Dr. Gibbons, Sr., entertained the Academy
with a very instructive and extemporaneous ad-
dress on Cloud Foundations and their Climatic
Influences.

Dr. Winslow mentioned that in 1853 he pur-
chased a particle of fossil he saw in a barber
shop window, on Kearney street, near Pacific.
The barber explained that he had procured the
bone from a well then being dug in that neigh-
borhood. Subsequently the doctor sent the
bone to Leipzig, and received word that it was
the bone of a mammoth sloth. The rest of the
skeleton is still in that place, corner of Pacific
and Kearny streets, and he thought something
might be done to secure it intact, since the
street there is being excavated.

HON. THOMAS H. SELBY, ex-Mayor of San
Francisco, died in this city on the 9th inst. Mr.
Selby has been identified with the business in-
terests of this city for many years. He has
held many responsible official positions during
his residence in California, all of which he has
filled with credit. Mr. Selby was a large metal
importer and proprietor of the shot tower and
extensive smelting works in this city, being
interested also in various other industrial en-
terprises. He was the first President of the
Industrial School Association, and also of the
Merchants' Exchange. He was President of the
Board of Trustees of Calvary church, and held
a similar position in the Board of Trustees of
the City College. He was also a life Director
of the Mercantile Library Association and an
old pioneer of this State, having arrived here
in August, 1849. Mr. Selby was so well known
among us that it is hardly necessary to speak
of his business relations. He died leaving a good
record behind him, as well as a large fortune,
figuring up among the millions.

Notices of Recent Patents.

Among the patents recently obtained through
Dewey & Co.'s American and Foreign Patent
Agency, the following are worthy of mention:

IMPROVEMENT IN CARRIAGES.—Francis Scherb
and Frank F. Doland, Sacramento, Cal. This
improvement in the construction of carriages,
consists mainly in a novel combination of two
forms of spring, and also in the means by
which the wagon bed is mounted on these
springs, so as to obtain steadiness and ease of
motion. The head block and rear axle are
united by reaches, and cross-bars are secured
to the reaches a short distance from the
head block and axle bed respectively, to
support the ends of the springs or pecks,
and also to allow the front wheels to be
cramped short in turning without touching the
springs. This part of the carriage is con-
structed after a patent issued to Francis Scherb,
September 28th, 1869. To the head of the
springs are united side springs which may be
made continuous or in two parts. A shaft or
bar extends across beneath the middle of the
wagon bed, and when the spring is made con-
tinuous the ends of this bar will pass beneath
the center of the spring. A rubber or other
elastic plate is secured between the spring and
bar to prevent wear. If the spring is jointed,
it may have its meeting ends bent around the
end of the bar like a hinge. Two other bars
cross beneath the wagon bed near each end, and
the ends of these bars are flattened so as to form
the upper leaf of the side spring and bolted or
clipped to the top of the springs at a point
midway between the shaft and heads. These
shafts pass through elastic cushions, which are
secured in boxes beneath the wagon bed, and as
the ends of the shafts are firmly bolted to the
springs, it will be manifest that any depres-
sion or change of angle in the springs will
cause the shafts to rotate slightly within the
cushions and thus relieve the strain. These
cushions also by their elasticity assist in re-
lieving the jolt and strain of any end motion,
caused by the roughness of the road. Adjust-
ing screws press against the moveable plates and
boxes, and thus serve to regulate the tension of
the cushions and take up any loss from the
deadening of the cushions, the device thus
forming an easy and comfortable carriage.

GRAIN SEPARATOR.—Elijah Knapp, San Fran-
cisco, Cal. This invention relates to improve-
ments in apparatus for separating wheat from
barley and the small grains with which it is
usually mixed. In carrying out the improve-
ment the inventor employs a hopper for the
reception of the grain and a screw or plain
roller in the bottom of the hopper for feeding
the grain upon the screen surfaces. The grain
falls upon a compound screen which is sus-
pended in an inclined position by its four cor-
ners, from the main frame. This screen is
provided with three or more sifting surfaces,
one above another, and in its construction and
application is not materially different from the
screens ordinarily used in separators. Below
this screen is mounted a sifter or screen at an
opposite inclination, and to this screen is im-
parted an up and down motion or jar. The
compound screen consists of three plates
placed one above another. The two upper
plates are perforated at the upper end, leaving
a plain plate section at the lower ends. The
lower screen plate has its lower edge also per-
forated. The grain will fall from the hopper
upon the upper end of the upper screen plate,
and as the entire screen is given a shaking
motion the wheat and smaller seed will pass
through the holes and fall upon the second
screen plate, leaving the barley and larger grains
to pass down over the apron of the lower screen
plate. The grain and small seeds which pass
through the perforations will pass down
through the two upper plates successively and
fall on the oppositely inclined screen below.
This oppositely inclined screen is made of wire
cloth in which the meshes are small enough to
prevent the wheat from passing through, while
the meshes are large enough to let small seeds
and dirt pass through. This screen is stretched
upon a frame which has an inclined bottom be-
low the screen. The frame is mounted on
springs both at its upper and lower ends so
that it is supported on them. A screen passes
loosely through a hole in the end timbre of
the frame at each corner of the screen frame
and is sorwed into the bottom. A rod extends
upward from the middle of each side of the
screen frame, passes through a staple in the
frame, and in the upper end of this rod a roller
is secured. The driver shaft extends across
the frame just above the upper ends of these
rods, and secured to the driver shaft above
each of the rollers is a four-armed cam. As the
shaft is rotated the arms of the cam strike the
roller on the upper end of the rod successively
and depress it, thus forcing the screen frame
downwards by compressing the springs upon
which it is supported. After the arms pass the
roller the springs will force the screen frame
upwards until the heads of the screws strike
the under side of the end timbers of the frame.
This gives the screen a peculiar motion which
will throw the grain upon it upward and thus
keep the meshes clear, while it favors the pas-
sage of the small seeds through the screen so
that they will fall upon the bottom. When the
compression of the supporting springs is re-
leased they will suddenly strike the timbers,
thus producing an upward throw and jar which
is very effective in separating the grain.

Short Lectures on Patents.
No. 8.—By JNO. L. BOONE, of Dewey & Co's MINING AND SCIENTIFIC PRESS Patent Agency.

Design Patents.
Inventions are divided into two classes. First, those that possess utility, and secondly, those which only relate to the ornamental without reference to utility. Where the invention possesses utility, in however small a degree, a mechanical patent is issued to cover it, but when it relates only to shape, form, configuration, or design; when it is intended to represent something which is pleasing to the eye, something beautiful, it is then characterized as a design, and a design patent is issued to cover it.

If an inventor applies a new shape to a stove, and that shape involves utility, it is the subject of a mechanical patent. But if the shape is only applied to the stove for ornament, without possessing utility, it is a subject for a design patent. The line of distinction between a mechanical patent and a design patent is sufficiently marked to prevent any one from mistaking the one for the other. The only question to be settled is, does this invention possess utility outside of the peculiar design or shape which it possesses? If it does not, then it is a design.

Frequently an invention comprises both a mechanical patent and a design patent. For instance, if a person invents a new and useful device, or machine, and he finds that although he can embody his invention in a dozen different forms, there is one particular form or shape that is ornamental and pleasing to the sight, he can have a mechanical patent on his improvement and a design patent on the design. But the design patent must be applied for and obtained previous to the mechanical patent, for if he first obtains his mechanical patent and represents the design in it, he thereby estops himself from taking out the design patent, unless he states in his mechanical patent that he intends to patent the design. This is to prevent the inventor from defrauding purchasers, for if he takes out a mechanical patent covering his invention, he might sell the right to manufacture, or an interest in his patent to another, and then by taking out a design patent covering the form or shape, prevent the purchaser from having any benefit from the right he has purchased. But if he first secures a patent on the design, it will not debar him from subsequently obtaining a mechanical patent.

So great is the mania of the present age for change and novelty, that designs, like fashions, no matter how popular they are when they are first introduced to the public, usually become stale in a short time and are replaced by others. Owing to this fact, the patent law provides for the granting of design patents for shorter periods than for mechanical patents. These terms are three and a half, seven and fourteen years, and the inventor may elect which term he chooses for his patent. The fees are granted in the same ratio. The inventor is thus made the only judge as to the probable permanency of his design.

Probably some of the most valuable patents issued by the United States Patent Office cover designs for carpets, cloths, stoves and burial caskets. These are articles which require ornamentation in order to suit the public taste, and when an inventor happens to secure a design that becomes fashionable in any of these articles his fortune is generally made.

When a person manufactures a machine, or article in a particular shape, or with a fixed design upon it, which could be patented, no other person has a right to apply that design upon a similar machine or article, and the design becomes a trade mark by which the machine or article is recognized in the market. The general or peculiar shape of the exterior of a package, or machine, fixes itself more firmly in the minds of most people, than any mark or brand which it has upon it, and frequently the design is the only mark or feature that the purchaser goes by in making his purchases. Most manufacturers know the value of securing an independent original design for their articles, and as the cost of design patents is not great, they can easily afford to protect themselves from imitations.

If an inventor applies for and obtains a design patent for three and a half years,—the shortest term—he cannot have it extended at the end of that time, neither can he have a seven years' patent extended. His judgment must be exercised in making his first application as to the length of time for which he desires the patent to be issued, and when the patent expires it cannot be revived or extended.

A single design patent cannot be obtained for two articles which are not ordinarily used together, nor where their relative positions are liable to be varied when used together, but each design must be applied for and secured by a separate patent.

The same rules of law that apply to mechanical patents with regard to infringements, are employed and recognized in design patents. It is an infringement if another party uses a design which is sufficiently similar to that patented to deceive or mislead the public. The general effect of the design is always taken into consideration in determining the question of infringement.

Tea.
Preparation for Market and Varieties Sold.
In our last issue we gave a partial description of the methods of cultivation of tea in Japan, concluding with some remarks on the way the leaves were dried. We now continue our description with illustrations showing a tea plantation under the shadow of the sacred mountain, Fusi-Yama, and young girls picking and sorting the leaves. After drying the next process consists in sifting and sorting the leaves, and this is done in another house where young girls are seated around flat tables with piles of tea in front of them. Before sorting the tea, it is well shaken in sieves of various sizes, to rid it of all dust and flake particles; then it is heaped upon the table; each girl

54,133,599 pounds. San Francisco imports of China and Japan for the past fifteen years, according to the San Francisco Journal of Commerce, have amounted to 79,487,522 pounds, worth \$29,735,417.

Seven-eighths of the teas sold in this market are Japanese, and these are daily coming into favor in the East.

Green Teas
Imported in San Francisco are divided into the following varieties: Moyune, Fy Chow, Teen Kai, Pingsney, Young Hyson, Twankay, Gunpowder, Imperial and Hyson. They come chiefly from the northern tea districts of China bordering on the great river Yang Tse Kiang. These teas are classed as divided into different varieties as: Gunpowder and Imperial of first, second and third class, and Hyson Skin and Twankays; fine young Hyson, first, second and third. The Moyune district is recognized as producing teas the most superior in flavor.

TEA PLANTATION—FUSI-YAMA IN THE BACKGROUND.

takes her left hand full of leaves and throws them before her on the tables, while with her right hand she picks out any stray stick, straw, or imperfect leaf, and sweeps the rest into a basket. This is done with great rapidity, and their fingers move in the same way as a hen uses her beak when pecking corn. The tea is sometimes still further sorted, when they wish to separate the fine, small leaves from the larger ones; the former always constitute the best quality of tea, while the latter forms the chief bulk of that which is exported to foreign countries. Of course the best tea remains at home, and the poorest goes abroad; but as we usually spoil its real flavor, with our milk and

Next comes Fy Chow and Teen Kai, which are rated as about equal in value. Pingsneys, although the best in appearance, are the poorest in flavor. All these teas are manufactured in Canton, but of low and medium grades.

Black Teas
Are produced in largest quantities in the districts of Oo Nsm and Hnh Pah. Here are produced Congous and Sou Chongs for the English market. In the neighborhood of Foo Chow is the principal producing district of Oolong, which are favorites in the United States. They are teas that run from 20 cents to \$1.50 per pound. The island of Formosa

SIFTING AND SORTING TEA LEAVES.

sugar fixings, perhaps it does not make much difference after all.

All that which is exported has to be "refined" again in Yokohama, or some other port. Here they do the thing on an immense scale in large stone houses, where hundreds of men and women are employed in heating and rolling the leaves again, and putting the "finishing touch" on the whole process; this is absolutely essential to preserve the tea and render it fit for transportation. In the firing ten per cent. in weight is lost. The fresh tea odors which greet you as you pass the open windows of these tea-firing establishments, are such as would make our lady friends smack their lips with delight. Such is the process of preparing tea for the market in Japan.

The consumption of tea has increased at a marvelous rate both in Europe and America during the past fifty years. The American Exchange and Review states that in 1711 it was only 141,995 pounds. In 1874 it was 137,442,264 pounds. In the United States the consumption in 1791 was 985,997 pounds and in 1874 it was

and the neighborhood of Amoy have, within the last five years, produced a large quantity of very superior Oolong, as also has Japan, and this last circumstance has urged the choice growers to extra exertions to improve the quality of their own. Specimens of all kinds of teas have been brought from time to time to this market, more as curiosities than anything else, among which we may mention the celebrated Mandarin tea and the Brick tea, which is sold at from 90 to 95 cents per pound. Frequently it is said teas have sold for less in the market than what they have cost to produce in Japan.

One great feature of the trade in this city has been the system of auction sales, which are held monthly, and sometimes oftener, and at which from 3,000 to 5,000 packages at a time are usually disposed of. There are in this city not less than twenty-five firms who import more or less, and most of whom also act as jobbers; and who have not less than a million and a half dollars invested in the business. This does not include those who are jobbers only, or who are retailers.

Hints on the Washoe Process.
(Continued from last week.)

The Results Obtained in Settlers, Agglalors, and Concentrators.
On drawing the charge, the greater part of the quicksilver runs quickly into the bowl or reservoir of quicksilver in the bottom of the settler, whence it flows out, free from sand, through a siphon, into a kettle outside. It is preferable to fill the settler, when the charge is drawn, with water falling as a rain, and, when the settler is full, to let nothing run out, but turn off the water and run the stirring-arm in the charge for an hour. This collects the floured quicksilver somewhat, and settles it. Then turn on plenty of water, and let the settler discharge through the top plug-hole as long as possible. The operation should be so timed as to reach the bottom hole of each individual settler only just in time to receive the next charge. The settler will never choke with heavy sand if the pan has ground well and the driving-belt is in good shape. In the settler accumulate some coarse sand, some un-reduced sulphurets, amalgam, quicksilver, and iron from the pans; and once a week the settler should be cleaned out, and the concentration reworked in the pans.

A good supply of water should be kept constantly running in the agitators. Here there will be found some coarse sand containing a little quicksilver, amalgam, sulphurets, and considerable iron; but the saving is very small. The floors throughout the mill should be kept clean, and the whole mill as neat and free from dirt as possible; no loose quicksilver should be found in the floors, on the table, or anywhere; all drains should lead into the agitators; and the quicksilver floor, unless the weather be too cold, should be washed with a hose every day.

Except on ores containing a large proportion of heavy sulphurets, or containing much slime that coats quicksilver, I have found but little benefit in concentrators applied to tailings from the pans. In ordinary cases, they collect little except iron from the pans and coarse sand. The pans grind so fine that the precious metal left in the tailings is very difficult to concentrate after leaving the agitators—provided the ore has been well worked. It is necessary to have a regular supply to the concentrator; and this may be effected with siphons of one and one-half inch and two inch pipe. I have found Hufferford's concentrators very good for slimes and slimy ores, since the shaking collects the floured and slime-coated quicksilver very well.

After leaving the concentrators, the tailings were run, in the Owyhee mill, over a double set of blanket sluices, 250 feet long; but it was found that on the ores then worked, the saving did not pay for the labor employed in frequent washing; and at last the blankets were worked only about once a week.

The Straining of Quicksilver, Cleaning of Amalgam and Retorting.
The quicksilver collected in kettles outside the settler is strained through canvas escks, the amalgam collected is cleaned from small mechanical impurities in a cleaning pan, then re-strained and retorted in an iron retort, beneath which fire is kept up for eight to twelve hours. The distilled quicksilver is condensed by a sleeve around the esock pipe, filled with water. After cooling, the retort is opened and the bullion is taken out and delivered to the assayer.

The retort is a source of considerable expense in milling. My experience leads me to prefer a cylindrical retort of cast iron, weighing about 1,200 pounds and fourteen inches by forty-eight inches inside dimensions. This style has various external shapes, doors, etc. The main trouble in retorting is this: with a long continued bright fiery red heat at the last, almost but not quite all of the quicksilver can be volatilized. The sublimation of the last one or one and a half per cent. cannot be effected without heating the retort till part of the hullion is melted, which requires a white heat. At this temperature the iron loses its tenacity, becomes spongy and rotten, and easily changes its shape. In a short time, under this treatment the retort becomes distorted, even if turned around frequently, and after a time it bursts, frequently volatilizing up the chimney 200 pounds of quicksilver. Three or four such experiences a year are rather expensive. I have made many experiments, such as retorting in vacuum, firing twenty-four hours at a moderate heat, etc., but finally concluded to braze the retort as well as possible, never heat it above cherry red, and submit to the loss of one per cent. of quicksilver for the present. In one's own assay office I think it can satisfactorily be assayed during melting, by a condensing chamber in the stack or chimney.

(To be Continued.)

The main north drift on the 1700-ft level of the Gould & Curry mine will have about 40 ft yet to run to connect with the south drift from the Best & Belcher. As soon as this connection is completed, and the necessary ventilation of the level obtained, cross-cuts will be started to out and prospect the ore vein at several different points, and some lively developments may be looked for.

OVER \$3,500 PER MONTH SAVED

BY THE USE OF

Hendy's Improved Amalgamator and Concentrator

Can be seen at the Manufactory, No. 32 Fremont Street, San Francisco.

JOSHUA HENDY, Esq.—Dear Sir:—As a practical miner and millman, I take pleasure in recommending the
use of your Concentrators in all mills where gold or silver ores are reduced. No mills should be without them,
for the following reasons:1st. They are good sizers (no perfect concentration in pulverized ores can be effected without first sizing).
2d. The best Concentrator I have ever known—(the concentrated stuff only containing 5 per cent. of sand).
3d. They are good amalgamators, light (feathery) particles of amalgam and particles of coated gold by at-
traction are brightened, and from their specific gravity and the action of the pan, fall to the bottom and adhere.
4th. They require but little power and attention to run them, and with ordinary care will last for years.
I have been familiar with the workings of your Concentrators for four years past; have run them myself in
the North Star Mine, Grass Valley; am familiar with their practical workings on the Empire Mine, Grass Valley;
St. Patrick, Placer Co.; St. Lawrence, El Dorado Co.; Oaks and Raess, Mariposa Co., and most cheerfully give
you this testimonial. For further information you are at liberty to refer to,
Yours respectfully,
JAS. H. OROSSMAN, M. E.

409 California street, or Cowmopolitan Hotel.

SAN FRANCISCO, April 27, 1872.

OFFICE SUPERINTENDENT OF KEYSTONE CO. M. CO., ANAHO, ANAHO COUNTY.
MR. J. HENDY—Dear Sir:—In answer to your inquiry as to your Concentrators furnished our company
last July, I would say that I am more than pleased with them; and the saving to the company has been over
\$3,500 per month more than with the blanks and boulders formerly in use.
O. O. HEWITT, Supt.J. HENDY, Esq.—Dear Sir:—Having four of your Concentrators in use at our Mills for four or five months,
which for saving Amalgam and for concentrating Sulphurets, are a success, beyond a doubt, I feel it a duty
due you and those interested in Quartz Mills, to recommend them.
As further evidence of their worth, I now order TWELVE more of your Machines for our new Mill, now in
course of erection.
E. R. BURKE, Superintendent.

For description send for Circular.

Miscellaneous Notices.

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently
introduced for general family use in San Francisco and
neighborhood, is already in great demand. It is now the
intention of the manufacturers to introduce it all over the
Pacific Coast, at prices which will bring it within the reach
of every household.
It is unequalled for cleansing Woolen Fabrics, Outlets,
Carpets or Crookery; for Scrubbing Floors, Washing Paint,
Removing Grease Spots, Shampooing or Soaking.
It renders water soft, and imparts a delightful sense of
cleanness after washing.DIRECTIONS.—For Laundry, use two to four table-
spoonfuls in the bath tub. For removing grease spots,
apply with a brush, and wash with water after-
ward. For stimulating the growth of plants, use a few
drops in every pot of water used in watering.PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bot-
tle, 40 cents; per Half Gallon, 75 cents.
Also, SULPHATE OF AMMONIA for chemical pur-
poses, fertilizing, and the preparation of artificial manures.
AMMONIACAL PREPARATION, for the prevention and
removal of boiler scale. CRUDE AMMONIA, for general
manufacturing, and PURE LIQUOR and AQUA AMMO-
NIA for chemical and pharmaceutical purposes.
Manufactured by the
SAN FRANCISCO GAS-LIGHT CO.
6v27-60wbp

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR
APPLICATION—requiring no thinner or dryer, and will
not spoil by standing any length of time.It is Cheaper, more durable, more Elastic, and pro-
duces a more Beautiful Finish than the best of any
other Paint.It will not Fade, Crack, or Peel off, and will
last twice as long as any other Paint.In ordering White, state whether for Outside or In-
side use, as we manufacture an Inside White (Flat) for
inside use, which will not turn yellow, and produces a
finish superior to any other White known.Put up in 1/2, 1, 2 and 6 gallon packages, and in
Barrels. Sold by the Gallon.For further information send for Sample Card and
Price List, or apply to the office.OFFICE AND DEPOT: 117 Pine Street, near Front. Cor. 4th & Townsend Sts.

Ayer's Hair Vigor

—FOR—
RESTORING GRAY HAIR
TO ITS NATURAL VITALITY AND COLOR.Advancing years, sick-
ness, care, disappoint-
ment, and hereditary
predisposition, all turn
the hair gray, and either
of them incline to shed
prematurely.AYER'S HAIR VIGOR, by
long and extensive use,
has proven that it stops
the falling of the hair
immediately, often re-
news the growth, and always surely restores its color,
when faded or gray. It stimulates the nutritive organs
to healthy activity, and preserves both the hair and its
beauty. Thus brashy, weak or sickly hair becomes
glossy, pliable and strengthened; lost hair regrows with
lively expression; falling hair is checked and stablished;
thin hair thickens; and faded or gray hair resumes their
original color. Its operation is sure and harmless. It
cures dandruff, heals all humors, and keeps the scalp
cool, clean and soft—under which conditions, diseases
of the scalp are impossible.As a dressing for ladies' hair, this Vigor is prized for
its grateful and agreeable perfume, and valued for the
soft luster and richness of tone it imparts.

PREPARED BY

DR. J. C. AYER & CO., Lowell, Mass.,
PRACTICAL AND ANALYTICAL CHEMISTS.

Sold by all Druggists and Dealers in Medicine.

CRANE & BRIGHAM, Wholesale Agents,
5v18-aa SAN FRANCISCO.This is a Sure Cure for Screw Worm, Scab
and Foot Rot in Sheep. It also kills Ticks,
Lice, and all Parasites that infest Sheep.Prevents scratching and greatly improves the quality
of the wool. One gallon of the Dip properly diluted
with water will be sufficient to dip one hundred sheep,
so that the cost of dipping is a mere trifle, and sheep
owners will find that they are amply repaid by the im-
proved health of their flocks.The Dip is guaranteed to cure when used according
to directions, and to be vastly superior to Quercuol
Sulphate, Sulphur, Tobacco, and other remedies which
have heretofore been used by farmers.Circulars sent, post paid, upon application, giving
full directions for its use, also certificates of prompt
cure, and sheep growers who have used large quantities of the
Dip, and pronounce it the most effective and reliable
cure and preventive of Scab and other kindred
diseases in Sheep. m13-bp

SAFE INVESTMENT.

The Pacific Coast Twelve Per Cent.
Consols.NEW METHOD WITH ASSURED AD-
VANTAGES.A rapidly growing interest is being taken in the
Pacific Coast Twelve Per Cent Consols, in consequence
of the many advantages offered in regard to invest-
ment, interest and dividends. So much uncertainty
exists in connection with nearly all mining and other
speculative companies, there is something very assur-
ing in an incorporation which not only guarantees
twelve per cent. per year to all stockholders, but pro-
vides for the honest payment of dividend. The Twelve
Per Cent Consols were incorporated on the 12th of
February last, for the purpose of transacting a general
business in buying and selling mining properties, city
real estate, and agricultural and other lands, in the
States and Territories of the Pacific Coast. Deter-
mined to do only a strictly legitimate business, the
Directors rejected the old method in vogue by mining
companies generally, and adopted a new one which
secures to all parties who become shareholders, equal
advantages in the business transacted. By the provi-
sions of the by-laws,

A Sinking Fund

Is to be made of one-half the proceeds of the total cap-
ital stock, which shall be sold on the joint account of
the original co-owners. The stock will be classified as
follows: Sinking Fund, mining property, city real
estate and agricultural lands. Before any stock is
issued in any class, the property will be appraised by
the owners, and the stated value entered upon the
books of the Company. Shares for not more than fifty
per cent. of the valuation will be issued in any of the
classes, and the amount of shares offered for sale in
any one class, exclusive of the sales of stock in the
Sinking Fund, will not be allowed to exceed 50,000,
if sold at less than the par value of a dollar per share.

Guarantees of Safety.

In regard to the Sinking Fund, which will constitute
fifty per cent. of the par value of the stock, all moneys
received as the proceeds of sales of stock on account of
the fund will be deposited with some solvent banking
institution, which pays interest on deposits invested
in interest bearing stocks, bonds and other securities,
which can be realized on at thirty days, and in no case
will it be lawful for the directors or trustees to invest
any moneys of the Sinking Fund in the purchase of
stocks, bonds or other securities of any incorporation
whatever, which shall have failed to pay interest or
dividends for a period of six months preceding any
proposed investment pertaining to the Sinking Fund of
the Company.

Payment of Interest.

The by-laws further make positive provision for the
payment of interest monthly on all stock issued in
each class at the rate of twelve per cent. per annum,
payable on the 5th day of each month. Another im-
portant concession is that any shareholder has the
option to take stock in payment for interest at par
value in any class that may be preferred. No assen-
ment will be levied until the total stock of the Sinking
Fund shall have been sold and paid out as provided by
the by-laws. Indeed, so secure is the plan of the Com-
pany that in case the whole capital stock of the Company
should be sold immediately and the Sinking Fund in-
vested as provided, the proceeds would be sufficient to
pay the interest for eight years and a half on the total
capital stock. Perhaps no other company in the world
has ever been able to present so brilliant a certainty.

Dividends.

Stockholders will not only be sure of their twelve
per cent. per annum, but will share in all the surplus
profits. The dividends will be paid from the profits
and sales of property, and only on shares of consols
that have been issued for property valued and entered
on the books of the Company. As there can be very
little question that the transactions of the Company
will be very extensive, and that the profits will rapidly
reach something handsome, the dividend prospect
should serve as a strong inducement to stock pur-
chasers, for perhaps in no other direction can they be
positive of receiving one per cent. a month for money
invested, and almost a certainty of large yearly di-
vidends is addition.A further provision can be made at any time by the
Company by setting aside the percentage agreed upon
of the sales of the properties of the Company. The
main object of the directors is to incorporate a more
legitimate and assured method of transacting business
in mining and property than has hitherto obtained on
this coast. They are therefore resolved to touch nothing
but bona fide investments, and to make it a rule to
have nothing to do with speculative values. Every
possible care will be taken to protect the interests of
shareholders; and in order that they may be constantly
posted in the transactions of the Company, a monthly
statement of affairs will be prepared by the officers,
and the books will be at all times open for inspection.
Shares for the first series issued for mining property
in Washoe, Storey and Lyon counties, and on the Coun-
ty side in Nevada, and for account of Sinking Fund,
will be ready for delivery to subscribers and purchas-
ers to-morrow, at Greenbaum & Co's, 308 Montgomery
street. The selling rate will be one-twenty, and the
buying rate one-nineteen. The principal office of the
Company is at 308 Montgomery street. T. Phelps is the
President, and W. S. Reynolds is the Secretary.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidity pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merit. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces.—Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., June 8th, 1875.

FOR WEEK ENDING MAY 25TH, 1875.

MACHINE FOR SAVING QUICKSILVER.—John W. Varney, Virginia City, Nev.

SPRING TRAOE CARRIAGE AND BACK LOOP.—Wm. Davis, Petaluma, Cal.

SHOE FOR WAGON BRAKES.—John Grimste, Milton, Cal.

PRINTERS' GALLEY.—Henry H. McWilliams, Sacramento, Cal.

TRACTION ENGINE.—William H. Miltiken, Sacramento, Cal.

RE-ISSUE.

HYDRAULIC ELEVATOR.—Timothy Stebins, San Francisco, Cal.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. Note.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

General News Items.

BEFORE her examination by the physicians which resulted in declaring her insane, Mrs. Lincoln carried \$57,000 in securities in her pocket. She also spent large sums of money, bought \$600 worth of lace curtains; three watches costing \$450; \$700 worth of jewelry; \$200 worth of Lubio's soaps and perfumery; and a whole piece of silk.

THE Sioux chiefs have returned from their visit to Washington, dissatisfied with their treatment by the authorities, and it is feared they will take revenge for supposed grievances by attacking the Black Hills pioneers.

Mrs. M. L. SANBORN is a candidate for Superintendent of Schools, in San Diego county, and as her qualifications are undisputed, and she is supported by papers of both parties, it is probable she will be chosen without opposition.

INDIOTMENTS have been found against several citizens of New York for complicity in the Tweed frauds, and the prosecution of all suits against members of the ring are being pushed vigorously.

AFFAIRS in the Pennsylvania coal regions are still in an unsettled state, and a collision between strikers and miners now at work, may occur at any time.

THE Atlantic cotton mills in Lawrence, Mass., employing 1,200 operatives, will shut down on account of the dull market, on July 10th, and remain closed till September 1st.

MISS MARY TELFAIR, who died in Savannah last week, bequeathed the greater portion of her estate, valued at \$1,000,000, to religious and charitable objects.

THEY have a zinc spring near Quicooy, Pinamas county, and already wonderful cures are reported from those who have quaffed its waters.

THE suspicion, for want of support, of the weekly journal, *Common Sense*, speaks well for the good sense of San Francisco people.

THE meeting of the National Photographic Society which was to have been held in this city next month has been postponed to 1877.

A FINE new barn belonging to Michael Rogers was burned in Sucoo, Alameda county, last Monday. Loss, \$15,000; partially insured.

W. H. TALCOTT, buyer for H. B. Claflin & Co., has been arrested on a charge of buying \$400,000 worth of smuggled laces.

A GERMAN named Gotthold Behrens suicided by inhaling charcoal fumes in this city, on Sunday last.

REPORTS from the Fiji Islands state that 50,000 of the natives have lately died of the measles.

REV. A. B. FISK, the new pastor of Howard St. Presbyterian church, preached his initiatory sermon last Sunday.

THE P. M. S. S. Co.'s new steamship *City of New York*, was launched at Chester last Saturday.

THE Aroy wine cellar Visalia was destroyed by fire last Wednesday. Loss \$4,000. Incendiarism.

THE International Typographical Convention has been in session in Boston this week.

THE German corvette, *Arcona*, lies at anchor within the portals of the Golden Gate.

GOONS intended for exhibition at the Centennial can be imported duty free.

COINAGE of twenty cent pieces has been commenced at the S. F. mint.

HUENEME now has telegraphic communication with the outside world.

THE American rifle team sailed from New York on Saturday last.

A NEW time table on the S. P. R. R. went into effect this week.

MODESTO thermometers marked 105° in the shade last Saturday.

THE small-pox is raging in New York city.

Industrial Items.

THE Lincoln fire clay has been used in the rolling mills at San Francisco, and found equal to the best Eastern quality. Two car loads of the clay have been used at Selby's works, San Francisco, and found satisfactory, and practical tests have been made in the potteries also at Oakland.

THE Butte Record says: It is announced that H. Hale & Son, of Petersburg, Ill., are willing to bring their woollen mills to California and take one-third the capital stock. Let them come to Chico, and they will not be obliged to repeat the offer.

IN Los Angeles the Board of Directors of the East Los Angeles and San Pedro street railroad have directed the president of the company to proceed at once to order the necessary material to build five miles of road, on the prismoidal plan, from the southern limits of the city to East Los Angeles.

LATE advices from San Fernando tunnel say that five hundred men are at work in the cut. The south end is 150 feet deep, and on the north end the work is on the approaches. Considerable trouble had been experienced from a cave of soapy sand.

MA. A. L. SRINSON, proprietor of the Pioneer hosiery manufactory at Jefferson, Oregon, has commenced operations, the carding and spinning rooms being under the charge of Mr. James Barnes, a gentleman lately from a large factory in the East.

COLLECTED returns made to the Bureau of Statistics show that 18,106 emigrants, of whom 9,049 were males, and 8,157 females, arrived at the port of New York during May, 1875.

A NEW planing mill is being erected by the Central Pacific railroad company near the ship yard. Its dimensions are 200x60 feet, and two stories in height.

A JOINT stock company has been formed in Guerneville to manufacture chairs, with a working capital of \$4,000.

FROM 1,200 to 1,400 men are now at work on the El Dorado ditch, about half of whom are Chinamen.

THE wharf at Santa Monica has reached 1,300 feet from the starting point.

Nature's Great Specific.

The Extraordinary Virtues of Bethesda Mineral Spring Water.

In this age of ceaseless activity and general excitement, there are so many influences at work to engender disease and enfeeble health that few persons possess sufficient physical stamina to enable them to dispense altogether with corrective and restorative agencies. Of course, under the circumstances, there are numerous specifics offered as efficacious in the several departments of disease. Experience, however, has proved that most of them are worse than useless, inasmuch as they either further impair the vital powers or aggravate suffering. Medical science, on the other hand, while it reaches the diagnosis of disease and is able to prescribe certain remedies to check for a time the progress of decay, does not, in the great majority of instances, restore the human system to its natural vigor and eradicate the seeds of disease which render health impossible while they remain.

A Wonderful Discovery.

Nature, however, has been more friendly to the human family than medical science *per se*, and the most malignant diseases have been brought under control by her agency. The cures, for example, effected by the use of Bethesda Mineral Spring Water have been of so remarkable a character as not only to attract universal attention, but to cause the utmost surprise in the scientific world. This discovery may truthfully be pronounced one of the most important that has ever been made in connection with disease, and as the reputation of the water is now established beyond all cavil, and its achievements as a specific conclusively demonstrated, nothing but the bare facts need be stated, for the tests have been so thorough and the results so satisfactory that nothing can really prejudice the case.

Triumph over Deadly Diseases.

There is no known remedial agent that can cure certain diseases as effectually as Bethesda Water. It is specified in all cases of diabetes, inflammation of the kidneys, inflammation of the neck of the bladder and urethra, inflammation of the bladder, dropsy, gouty swellings, stoppages of urine, albuminuria, rosy or cloudy urine, brick dust deposits; thick, morbid, bilious and dark appearing urine, with bone dust deposits; burning catarrhs with sharp stings and burning urine; hemorrhages of the kidneys; pain in the kidneys and loins, torpid liver, indigestion, calculus, and female weakness.

Almost as soon as the water was discovered its great virtues were established in the most positive manner. One followed upon cure, marvels succeeded wonders, the most agonizing form of disease succumbed to this potent and all powerful remedy, the hopelessly lost regained their strength, the doomed were restored to health, shriveled, shrunken, helpless beings were brought back to life, men anured to long suffering and bitter anguish revealed in the relief of restored powers, while here and there and everywhere the magic of Bethesda, the certainty of its cure, and the marvel of its work was heralded as doing the work of miracles. Its discoverer was beginning to be appreciated; the taint, the jest and the sneer fell as before some superior power, and where ridicule had been instituted admiration took its place; while encouragement to the man, praise, laudation and favor occupied all places and claimed every attention.

What is Claimed.

The water has restored thousands from the brink of the grave; given health and strength to those deemed beyond the reach of all medical science, and turned the path of affliction to one of happiness in the blessings contained within its virtues. It cures the deadly Bright's disease of the kidneys, the disease which restores the urinary organs to strength and power; is a certain specific in dyspepsia; and unfailing antidote to a diseased and poisoned system from any and all causes; a sure agent in all cases of debility, nervous prostration or loss of power; acts with nerving certainty in giving new life to a languid and overtaxed system—in a word it is a natural restorer of health and has performed the most wonderful and miraculous cures of any known specific on the globe.

The agents everywhere have numerous testimonials in proof of the wonderful cures effected, and the sales of the water are greatly on the increase in every State of the Union. The general agents in this city are Dunbar, Handry & Lavery, at 107 Stockton street.—*Evening Post.*

"KNOW THYSELF."

The great educator, profound thinker, and vigorous writer, Herbert Spencer, has wisely said: "As vigorous health and its accompanying high spirits are larger elements of happiness than any other things whatever, the teaching how to maintain them is a teaching that yields to no other whatever." This is sound sentiment, and one great want of the present age is the popularization of Physiological, Hygienic and Medical science. No subject is more practical,—none comes nearer home to every man and woman than this. "The People's Common Sense Medical Adviser, in Plain English, or Medicine Simplified," by R. V. Pierce, M. D., is a book well calculated to supply a manifest want, and will prove eminently useful to the masses. It contains about nine hundred pages, is illustrated with about two hundred wood-cuts and fine colored plates, is printed upon good paper, and well bound. It is a complete compendium of anatomical, physiological, hygienic and medical science, and embodies the latest discoveries and improvements in each department. It has been the author's aim to make the work instructive to the masses, and hence the use of technical terms has been, as far as possible, avoided, and every subject brought within the easy comprehension of all. An elevated moral tone pervades the entire book. While it freely discusses, in a scientific manner, the origin, reproduction and development of man, it does not cater to depraved tastes, perverted passions or idle curiosity, but treats to a chaste and thorough manner, all those delicate physiological subjects, a proper knowledge of which acquaints us with the means for preserving health, and furnishes incentives to a higher and nobler life. The author, who is also the publisher of his work, anticipating a very large sale for it, has issued twenty thousand copies for the first edition, and is thus enabled to offer it (post-paid) at one dollar and fifty cents per copy,—a price less than the actual cost of so large a book, if published in only ordinary-sized editions. The large number of subscribers received for it in advance of its publication, has very nearly exhausted the first edition almost as soon as out, and those desiring a copy of it will do well to address the author, at Buffalo, N. Y., without delay.—*Com.*

EGGS, fresh, pure, packed so as to hatch after arrival on
any part of the Coast. For Illustrated Circular and Price-
List, address
M. EYRE, Napa, Cal.

[Please state where you saw this advertisement.]
Female Complaints should be cured, as they often
are, by a few doses of Ayer's Sarsaparilla.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT
for DIAMOND POINTED DRILLS, now brought to the
highest state of perfection, are prepared to fill orders
for the IMPROVED PROSPECTING and TUNNELING
DRILLS, with or without power, at short notice, and
at reduced prices. Abundant testimony furnished of
the great economy and successful working of numerous
machines in operation in the quartz and gravel mines
on this coast. Circulars forwarded, and full informa-
tion given upon application.

A. J. SEVERANOE & CO.
Office, No. 315 California street, Rooms 16 and 17.
24-26-27

water power, with houses, shops, etc. Government
title; joins the Providence mine, on Deer Creek, Nevada
City, Cal. For sale or to bond.

Address, I. S. VAN WINKLE,
413 Market street, San Francisco.

Mining and Other Companies.

California Consolidated Mill and Mining
Company. Location of principal place of business,
San Francisco, Cal.

Notice.—There are delinquent upon the following
described stock, on account of assessment levied on
the 1st day of April, 1875, the several amounts set
opposite the names of the respective shareholders, as
follows:

Names.	No. Certificate.	No. Shares.	Amount.
Burke, T.	33	100	\$ 50 00
Burke, T.	34	50	25 00
Burke, T.	35	50	25 00
Hendy, Joshua, Trustee.	84	70	35 00
Hendy, Joshua, Trustee.	73	24,550	12,275 00
Hendy, Joshua, Trustee.	73	2,118	1,059 00
Heardon, John.	80	50	25 00

And in accordance with law, and an order of the
Board of Directors, made on the 1st day of April, 1875,
so many shares of each parcel of said stock as may
be necessary, will be sold at public auction, at the office
of the company, 408 California street, room 16, on the
18th day of May, 1875, at the hour of 1 o'clock P. M.,
of said day, to pay said delinquent assessment thereon,
together with costs of advertising and expenses of sale.

J. W. TRIPP, Secretary.
Office, Room 16, No. 408 California street, San Fran-
cisco, Cal.

POSTPONEMENT.—The above sale is postponed
until Tuesday, the 15th day of June, 1875, at 2 o'clock
P. M. By order of the Board of Directors.
J. W. TRIPP, Secretary.

Carbon Coal Company.—Location of Prin-
cipal place of business, San Francisco, Cal.

Notice.—There are delinquent upon the following
described stock, on account of assessment levied on the
first day of May, 1875, the several amounts set opposite
the names of the respective shareholders as follows:

Names.	No. Certificate.	No. Shares.	Amount.
J. W. Harker.	Unissued	100	\$125 00

J. Martenstein & Co.	Unissued	100	125 00
L. A. Booth.	Unissued	100	125 00

And in accordance with law, and an order of the
Board of Directors, made on the first day of May, 1875,
so many shares of each parcel of said stock as may
be necessary, will be sold at public auction, at the office
of the Secretary, No. 220 Clay street, San Fran-
cisco, on the fourteenth day of June, 1875, at the hour
of one o'clock P. M., of said day, to pay said delinquent
assessment thereon, together with costs of advertising
and expenses of sale.

N. O. FASSETT, Secretary.
Office—No. 220 Clay street, San Francisco, California.

Cordillera Gold and Silver Mining Com-
pany. Location of principal place of business, San
Francisco, Cal. Location of works, Morelos Mining
District, State of Oahuahu, Mexico.

Notice is hereby given, that at a meeting of the Board of
Directors, held on the 8th instant, an assessment of Ten
cents per share was levied upon the capital stock of the
company, payable immediately, in United States gold
coin, to the Secretary, at the office of the company, No.
321 Washington street, San Francisco, Cal.

Any stock upon which this assessment shall remain un-
paid on the 18th day of June, 1875, will be delinquent,
and advertised for sale at public auction, and unless payment
is made before, will be sold on Saturday, the 3d day of
July, 1875, to pay the delinquent assessment, together with
costs of advertising and expenses of sale. By order of the
Board of Directors.

HENRY R. REED, Secretary.
Office, No. 321 Washington street, San Francisco, Cal.

Geneva Consolidated Silver Mining Com-
pany.—Principal place of business, City and County of
San Francisco, State of California. Location of works,
Cherry Creek Mining District, White Pine County, State
of Nevada.

Notice is hereby given, that at a meeting of the Board of
Directors, held on the 13th day of May, 1875, an assess-
ment of twenty-five cents per share was levied upon the
capital stock of the corporation, payable immediately, in
United States gold coin, to the Secretary, at the office
of the company, Room 14, 302 Montgomery street, San
Francisco.

Any stock upon which this assessment shall remain un-
paid on the 14th day of June, 1875, will be delinquent,
and advertised for sale at public auction, and unless payment
is made before, will be sold on Wednesday, the 30th day of
June, 1875, to pay the delinquent assessment, together with
costs of advertising and expenses of sale.

I. T. MILLIKEN, Secretary.
Office, Room 14, 302 Montgomery street, San Francisco
Cal.

Martin & Walling Mill and Mining Com-
pany. Location of principal place of business, San
Francisco, California.

Number 25.

An Improved Window Sash.

The accompanying illustration is an improved arrangement, recently patented through the agency connected with this office by John J. Price, of this city, for raising, lowering and locking the upper sashes of windows, and also to provide a lock or fastener for the lower sashes. The first arrangement consists in so arranging one of the weights which assists in balancing the upper sash that it will operate as a slide inside of the window casing, and then applying the force to raise and lower the weight instead of applying it to the sash. As the weights exactly balance the sash when hanging freely in the casing, the lifting or lowering of the slide weight will raise or lower the sash. The second improvement consists in the employment of a snap catch on the bottom rail of the lower sash, which will automatically lock into the sill of the window frame when the sash is drawn down against the sill.

The upper sash is balanced by two weights, one on each side of the casing. One of these weights, *d*, is arranged to slide up and down in ways in the lower part of the casing. The cord which connects the sash with this weight passes over a pulley in the top of the casing in the usual way, and is then carried down under the pulley in the sliding weight, *d*, and thence is carried up inside of the casing to the top of the window frame, where it is fastened at *c*. The weight pulley, *d*, will then travel in the height of the cord, and will only have to raise and lower a little over one-half the distance in order to raise and lower the sash that it would if the end of the cord were attached directly to the weight, *d*. The weight in the opposite side of the casing is suspended in the ordinary way.

In the facing of the casing directly in front of the sliding weight, *d*, is made a vertical slot, *b*, which is as long as the weight, *d*, will have to travel in order to raise and lower the sash. A metal plate, which is slotted to correspond with the slot in the casing, is sunk into the outside of the casing, so as to be flush with its outside face, and one edge of the slot on this plate is provided with teeth, *e*, as shown.

The shank of an ornamental button, *a*, passes through the slot and is fastened to the sliding weight, *d*, inside of the casing, while the button, *a*, remains on the outside. The shank is so constructed that by turning it to one position it will move up and down freely in the slot, but by giving it a half or quarter turn in either direction it will lock into the teeth, *e*, and fasten the weight firmly in place. Now, as the sash is balanced by the two weights, very little power is required to raise and lower it, and this power is applied to the sliding weight, *d*, through the button, *a*, and its shank.

By turning the knob or button, its shank is released from the teeth, when a slight upward or downward pressure applied to the button will raise or lower the weight and upper sash to any desired point, where it can be again locked by turning the button so that it cannot be opened further until the weight is released; and as the weight travels in this height of the cord, a short movement of the button up or down will completely raise or lower the sash, thus bringing it within the reach and power of the merest child to raise and lower the upper sash. This arrangement also avoids the trouble of having to raise the lower sash in order to reach outside and grasp the lower rail of the upper sash to raise or lower it.

The lower sash is provided with a snap catch, *f*, which automatically hooks into a recess in the sill of the window casing, or in the strip which is secured upon the sill. This catch is unlatched by lifting upward upon a projecting lever handle, which is so connected with the hook, *f*, that by lifting upward on the lever handle or finger catch, the hook is forced backward, and released from its catch. The lower face of this hook is inclined so that when the sash is closed down it will be forced backward and automatically fastened.

By this means Mr. Price provides a greatly improved arrangement for operating and locking window sashes. Where three or more sashes are placed in one window opening, the

upper sashes can all be balanced and operated by sliding weights as described for the upper sash, and in this case the sliding weights which operate the different sashes can be placed on opposite sides of the window. The slot, *b*, can be made on the inside face of the casing if preferred, and the locking shank inserted through it, and fastened in the weight as above described, but this can be arranged according to convenience. It is not absolutely necessary that the lifting weight should slide in ways, but it is much preferable to so construct it. Those desiring further information

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

MOUNTING HEADER REELS.—Frederick Wyman, San Buenaventura, Cal. This invention consists in so mounting header reels that the belt which drives the reel will preserve a uniform tension when the reel is raised and lowered. In the ordinary construction of

along each portion of the hinged front, so that a pen or pencil can lie in this groove and a single elastic strap about the middle of the holder will press the pencil against the hinged front so as to keep it closed without the necessity of an additional strap. It also consists in the use of a temporary memorandum plate or tablet upon the inside of the hinged leaf.

IMPROVEMENT IN WATCHES.—John Gordon, San Francisco, California. This improvement relates to that class of watches in which a permanent winding device is secured to the winding post so as to be contained and operated in a recess or well in the inner case of the watch. This improvement consists in attaching the winding lever bar or disk to the winding post of the watch in such a manner that any attempt to wind the post in the wrong direction will release the lever bar or disk from the post without turning it, thus preventing the watch from being strained or injured. Upon the winding post the lever, bar or disk is secured so as to lie in the well or recess and so that it can be turned towards the watch by inserting the fingers into the recess. Heretofore the bar, lever or disk has been either permanently secured to the winding post or the square post has entered a square socket in the bar or lever, so that the post cannot be turned in either direction. Instead of attaching the lever, bar or disk permanently to the post, Mr. Gordon forms the upper end of the post into a screw. The lever or bar has a hole through it which is tapped with screw threads to fit the screw or upper end of the post. The bar or disk is then screwed down upon the post, and will serve as a lever to wind the watch so long as it is turned in one direction, but when it is turned in the other direction it will unscrew from the post without turning it, thus greatly improving the winding device and preventing frequent injury by an accidental turn of the post in the wrong direction.

FEED AND REVERSE MOTION FOR SAWMILL CARRIAGES.—Frank M. Covell, Los Gatos, Santa Clara county, California. This is an improvement in that class of forward and reverse feed mechanisms for sawmill carriages, which operate by means of friction devices, and it consists in the use of a small pulley so mounted upon a shaft that it stands between the outer face of a small pulley mounted upon one shaft, and by moving the small pulley a short distance in either direction it can be brought in contact with either of these faces, thus giving motion in either direction to the shaft of the double pulley. The invention also comprises a novel method of mounting the movable pulley shaft and a lever by which it is thrown into one pulley face or the other. The whole device greatly simplifies the feed and reverse motion of the carriage.

PHOTOGRAPHIC PLATE HOLDER.—Isaiah W. Taher and Thos. H. Boyd, San Francisco. This improvement in plate holders consists in a novel arrangement by which the inventors are able to employ only two pieces inside of the plate holder frame instead of the large number of pieces usually employed, in order to accommodate the different sizes of plate and adjust them to the center of the plate holder frame. The holder is so arranged that they can accommodate the various sizes of plates by adjusting the tray and covers to or from each other, according to the size of the plates. It provides an exceedingly simple and cheap arrangement for holding the negative plate and receiving the drippings of silver, while the pieces can be readily adjusted to the various sizes of plates.

The matter of supplying the town of Fulton with water from Mark West creek is now under discussion. The fall from Rector's mill to the town, two miles, is 83 feet.

The new hoisting machinery of the Niagara mine, on the Comstock, has arrived and is being put in working position.

Some fifteen acres of porcelain clay have been discovered near San Fernando. Also, a rich vein of zinc ore not far from Los Angeles.

Fig. 1.

IMPROVED WINDOW SASH.

Fig. 2.

on this subject can address the inventor, John J. Price, 521 Brannan street, San Francisco.

ABANDONED MINES.—The Calaveras *Citizen*, in speaking of West Point district, states that abandoned mines are relocated nearly every day. Strangers are flocking in from all directions to secure an interest in old "worked-out" mines which were to be had one year ago for one dollar per dozen. Competent miners can find employment.

The Europa mine machinery for the new hoisting works is now on the ground, the foundations ready, and grading for the building about completed. As soon as the requisite timbers can be procured, the machinery will be placed in position, and will be running in the course of a couple of weeks.

The Crown Point mine, on the Comstock, hoisted nearly 17,000 tons of ore last month.

headers, the lever arm which supports the header reel at each end, and by which it is raised and lowered, is pivoted to upright standards at each end of the header frame, and this pivot serves as a center about which the reel moves when it is raised and lowered, while the pulley which drives the reel belt is below and at the rear of the pivot so that when the reel is raised and lowered the belt is alternately slackened and tightened. Various devices have been devised for remedying this difficulty, some of which have been successful but clumsy and liable to get out of order. By the arrangement patented, this inventor preserves the tension of the belt at whatever point of the reel the belt is moved to.

BILL FILE HOLDER.—F. B. Alderson, San Jose, Cal. This invention relates to certain improvements in temporary bill holders such as are employed to carry bills, letters, or other papers for present reference, and it consists in the formation of a groove or slot extending

CORRESPONDENCE.

Nevada County Mines.

[From our own Correspondent.]

EDITORS PRESS:—Leaving French Corral and taking the up grade along "the ridge," a moderate day's ride takes us through the old-time towns of Birchville, Cherokee, Bloomfield, North Columbia, North San Juan, and Relief Hill. The mere mention of these to an old California miner awakens in his mind a vivid remembrance of early days, when "Gold—money hunted, sweat and blood for gold," and he recalls the time when there was rushing in hot haste to and fro all over these wooded hills, and the mountains trembled and the trees waved their branches, as the deep and rock-walled canyons gave echo to the giant blast. As these thoughts crowd his mind, he smilingly muses on the old canvas hose and primitive nozzles that then were the pride of the more fortunate miners. All these camps or towns lay claim to being located in the great "channel" or gold-bearing gravel belt that traverses this part of California. While there is somewhat of mining going on in most all these places yet a cry is heard like unto that that was uttered with imploring zeal by the rich man in hell: "Give us water—more water!" But here the analogy ends, as we learn from sacred history that the unfortunate rich man wanted only *one drop* of water to cool his parched tongue, or lave his burning brow, while these burghs want *floods* of water sufficient to tear out the bowels of the hills and bring about that state of affairs that begets the fevered brain—a great mining excitement.

At North San Juan—

The prettiest and perhaps largest town on this range—the surrounding country bears evidence that there are those among the population who have quit the precarious occupation of the hunt for gold, and turned their attention to the plow and pruning hook. The broad undulating fields of grain, whose verdure paints the sloping hillside, with the thrifty growling vines, and blooming orchards that dot the landscape as we view it from some lofty eminence—together with the quiet little village cozily nestled down in the forest—all these give to the scene such a pleasant charm as to make the bolder wish that his home was on the mountains.

Relief Hill,

Formerly a lively camp, had been until quite recently almost entirely abandoned. Now, however, they have got in a better supply of water and there seems to be a new life infused into all the population and there is a real buzz of business perceptible. Old claims are being reopened, and every prospect seems encouraging.

Your correspondent will not soon forget his first visit to Moore's Flat. At six o'clock in the afternoon he left Relief Hill, six miles distant from Moore's Flat, and after an hour's ride over a rough road with innumerable by roads to mislead him—found himself apparently no nearer Moore's Flat than when he set out on his journey. He stood where three roads diverged, in the deep solitude of a gloomy forest, and darkness drew on apace. There was no sign of human habitation. Hundreds of feet above him, on the topmost bough of a gigantic pine, sat a night bird that had apparently just shaken off his drowsiness, and was watching with eager eye the play of the fast fading sunbeam on the snow topped peak beyond. He cast his eyes to the northward, and as the last glimmering ray reflected from them, raised himself to his full height, flapped his wings in triumph, and blinked his great eyes with perceptible satisfaction—and while the vesper bells throughout the world were bidding sons of toil to cease their labors and turn their thoughts to heaven, he—bird of darkness—l—took forth his *matin lay*, and the woods and the hills were full of doleful echoes. Alone, and in a strange forest, the denseness of which added tenfold to the darkness of the night—your correspondent felt that "though churchyards gape and yawn and ghosts sit on the tombs, he'd choose to ramble 'mong the graves where dead men slept than keep society with the forest ghouls at night time." Shutting his eyes to the fluttering shadows, and trusting to the agency of his horse to take the right road, a horseman swift darted through the trees, across the pebbly brook, then up the hillside, through the manzanita brake, then down! down! Moore's Flat, and nine o'clock has struck.

When morning dawns Moore's Flat presents on a business air now a days, for this winter just past, they have not been snow-bound, which is an escape worthy of remark, and very unusual at Moore's Flat. They have a stage running regularly, and the result is that they have kept in constant communication with the outside world for 365 consecutive days.

Messrs. Marks & Co. have a

Large Water Ditch

Running by Moore's Flat, and from this source the mines thereabout get their water supply. There are some good mines here, but there is

no mining being done except in the Chinese and Illinois mines. At the blue bank they are running a tunnel for an outlet. The Esigs mine, which has formerly been worked quite extensively, is now lying idle.

Mr. Henry McNulty (who, I must here remark, is a 49er), tendered his service as companion and guide to me, and gave me much insight into the working and controlling of the water ditches, the disbursement of the water, etc. He has charge of the ditch that supplies the mines, and it is worth one's time to take a tramp along the flume in company with him. He has resorted to various ingenious devices for his own convenience in controlling the gates opening into the different flumes. At two points where the gates in the main ditch are high upon the hill, and difficult of access, he has what he calls "a system of telegraphy," whereby he can open and close the slips; at will, and yet be hundreds of yards away. This gentleman is also proprietor of a slaughtering and butcher establishment, and he has the most complete arrangement for the prosecution of this business that we have ever seen. As a general thing, a slaughter house is rendered conspicuous by the stench that pervades the surrounding atmosphere, and is the last place that we would think of visiting, for we are unfortunately rather epicurean in our tastes and the more ignorant we are of the internal workings of such an establishment, the more we relish the viands set before us. But we are glad to testify that Mr. McNulty's shops are an exception to the rule, for we failed to observe anything in the entire manipulation of the various meats, that would be offensive to the most fastidious. He has, in every department of this business, mechanical appliances of his own conception and construction that reduce the manual labor at least a third, and what is more worthy of notice, there is perfect ventilation throughout, and everything looks as bright and neat as the show cases in a milliner's shop.

All these towns up the "ridge" have enjoyed more prosperous seasons than now, and Moore's Flat, with the rest, can mourn over departed glory, yet its populace are by no means unhappy. L.

Mining Industry.

(Written for the PRESS by J. E. OLATON, M. E.)

The Stone Age.

Before man learned to mine and work the metals, he had to depend upon the use of implements made of stone, wood, bone, and horn for weapons of defence and offence against the wild beasts of the forest, and neighboring hostile tribes. For long ages the early races of man knew nothing of metals. Stone hatchets, stone knives, and articles of bone and horn are found in abundance in the old drift deposits of Europe and America, but no traces of any metallic implements in the early haunts of primeval man.

The Age of Bronze.

The first step in the advancement of the human race was made when native copper, (and perhaps silver) was discovered, and came into use for weapons and domestic purposes. The tribes that first used copper were able to overpower their neighbors on account of the superiority of their class of arms for destruction, and it is fair to presume that the localities from which the copper was derived were guarded with jealous care to prevent their neighbors from supplying themselves with like material.

In process of time it was discovered that other metallic substances would combine with copper, forming various alloys that gave the metal much greater hardness and durability.

The Aztecs and Peruvians carried the manufacture of bronze to great perfection; their chisels and other implements for cutting stone are unsurpassed in hardness and durability by any metals or alloys of the present day.

The art of making copper tools and giving them hardness equal to the finest steel was known to them, but it has been lost in the destruction of those nations by the so-called Christian Spaniards.

The civilization of the Montezomas and Incas was confined within the limits of the supply of copper and bronze. There was not enough of these metals obtained to allow their universal use by the masses, hence they remained in comparative ignorance and poverty.

The mechanical arts so far as they could be developed by this limited supply were confined to a class, and they as usual in such cases were under the control of the priest and rulers of their respective countries.

The Age of Iron.

The nations of the Eastern continents had made much greater advances in the discovery and uses of other metals than those of the Western. The art of reducing iron from its ores and working it into all kinds of shapes and forms for use, gave a much wider field for the development of the mechanical arts among the masses. Its great abundance and universal distribution, and the ease with which it could be wrought into useful forms, gave an impulse to mechanical industries and manufactures which had been unknown to man before iron began to supplant copper, bronze, and brass implements. By a careful study of the early civilization of different races, in all parts of the world, we discover that such civilization was always limited by the supply of useful metals and their knowledge of working them into useful forms.

Where the supply was small, and the knowledge of their uses and manufacture confined to a few persons, the advancement of the races was slow, and in fact confined within very narrow limits. Their condition was due, firstly, to the limited supply of the crude material; secondly, to their ignorance of the best modes of producing the metals in useful forms; and thirdly, their poverty in the possession and use of metals, made one portion of them an easy prey to their more fortunate and powerful neighbors. Thus through the dim past we can trace the influence of the mining and working of metals upon the growth of civilization.

Those nations, and races of men who have learned to mine and work useful metals, have become powerful, have subdued their less fortunate neighbors, have collected the wealth of surrounding tribes, and made them tributary to their growth and power. The miners and metal workers in time became masters of the world, and in the higher sense they are masters of the world to-day. In brief, a careful reading of the history of civilization will show that those nations that learned to mine and work metals, became civilized, wealthy and powerful, while those races that never established mining industries and the manufacture of metallic articles have always been savages, and are savages to day. The conclusion therefore is inevitable, that mining, as an industry, is the oldest known to our race, and that it has been, as it is now, the foundation of the whole structure of civilization, the chief element of progress and the basis upon which all other industries rest.

I have thus briefly traced out the influence of mining industry upon the civilization and advancement of those races that learned to mine and work copper and its useful alloys, and the more universally distributed and still more valuable metal—iron. I now proceed to consider the uses and influences of the precious metals,

Gold and Silver.

Upon the continued advancement of the human race up to the present time.

Gold and silver were, no doubt, both of them known to the ancient races long before the manufacture of iron was discovered, but they possessed but very little importance on account of their limited supply, their softness rendering them unfit for weapons, or tools and instruments for mechanical purposes; and hence they were used mainly for ornamental purposes, thus becoming vehicles of trade and exchange between different tribes for articles of use and necessity. This naturally led to the adoption of these metals as the representatives of value among all nations and tribes of men, and they became the universally recognized standard of values and the medium of exchange in all commercial transactions.

During the age of despotic governments, when the national power was centered in a king or an irresponsible party, the precious metals as accumulated were, by command, deposited in the national treasury, thereby enabling the ruling sovereign to wield an enormous power over his subjects and use the means at his disposal according to his whim or fancy, alike for the purposes of conquest, the construction of fortified cities, works of national utility, or the erection of temples and palaces. While the building of temples and palaces may have been acts of folly on the part of the rulers, and the people may have been oppressed and impoverished by the burdens thus laid upon them, yet, nevertheless, benefits were derived which were of lasting importance.

These benefits were the growth of general intelligence, the development and extension of mechanical arts, the establishment of manufacturing industries and the encouragement of agriculture to keep up the necessary supplies of food for maintaining the great armies of miners, quarrymen, stone cutters, artisans and mechanics of every description.

Without the use of precious metals as a representative of value, there could be no great concentration of power over large populations or widely extended territories; but with large accumulations of gold and silver, extensive establishments for the manufacture of iron in all its various branches and divers uses could be maintained, and the highest order of skill developed, by the constant and long continued employment of the best mechanics of the day. Thus great cities were built up around these manufacturing centers, composed in the first place of artisans and their families, and afterwards by accessions from all classes engaged in commercial and manufacturing enterprises, and in time these cities became the centers of wealth, intelligence and political power.

Mining industry furnishes the material for all classes of tools and implements by which other industries are made possible; it is the basis of mechanical arts, and has given man the power to subdue and control all things in nature that are necessary for his physical, intellectual and moral well being.

The above outline of the origin of mining industry, and its influence upon the growth of civilization, the establishment of agriculture, manufactures and commerce, will show beyond reasonable doubt that the arts of mining and working the metals are the oldest known to the human race, and are the basis upon which all other branches of human industry rest. Mining industry is, therefore, the bed-rock or granite foundation upon which our present civilization is reared in all its grandeur and beauty. Agriculture, manufacture, commerce and the fine arts could not be developed until mining and working the metals was first estab-

lished, so as to put tools and implements into the hands of every man, woman and child, with which they could cut, hew and dig their way up to the place of civilized life. We often hear financial and commercial men ask the question why mining can't be made

A Legitimate Branch of Business.

A reliable industry, like manufacturing and commercial pursuits. The above historical review of its origin, progress and all pervading influence upon the civilization of the present age, is the best answer that I am able to give to such questions. When capitalists bring to the bosom of mining the same amount of skill and care that is bestowed upon manufacturing and commercial pursuits, we will hear fewer complaints about the uncertainties of mining as a legitimate branch of human industry. So much for the defense of mining as a business. I have now

A Few Questions

For the consideration of bankers, manufacturers, capitalists and commercial men, in relation to the risks and uncertainties connected with their several branches of business, to-wit: The capitalist invests his money in building up cities, that are in perpetual danger of being destroyed by fire, flood or earthquake. He builds great ships that are in perpetual danger of going to the bottom of the ocean. He invests in railroads and canals that may never pay a dividend. He invests in the bonds of governments that are in perpetual danger of being revolutionized, or swept out of existence. He establishes manufactories that may be destroyed by fire, by competition, or by a change in tariffs. He establishes banks that may at any time be overwhelmed by financial changes and political revolutions. He may finally engage in agriculture as the

Safe and Sure Thing

To bring certain returns for his investment, but here, too, he is met by risks over which he has no control. Untimely frosts, unusual floods, a season of drouth, or perhaps an over supply for the market, a flight of locusts, or the destructive march of an army of grasshoppers, or men may make of his farm a desert waste. Where, then, can you invest your money without encountering risks over which you have no control? Echo answers "where?"

The truth is that every branch of human industry must encounter risks beyond the control of human power, or the grasp of the intellect to foresee. It therefore is but a question of minimum risks and maximum returns for the capital, skill and labor that is to be invested in any and all branches of human industry. Can those who speak sneeringly of mining industry truthfully point out greater risks for it than for other great branches of productive labor? I think not. I refer now to mining for the precious metals, and I ask a careful and honest consideration of the risks, as compared with every other branch of human industry.

Mining Risks.

The first and greatest risk is in the search for and exploitation and development of the mining property to be operated upon. This risk may be small or great, in proportion to the intelligence and skill of the person engaged in the selection of the mines. When a suitable mining property is found, and the explorations intelligently made, we still have the second risk to encounter. The mine may pinch out or become poor at some depth below the surface; all mines are liable to this risk, and knowing this we must guard against extravagant expenditures, or any expenditures that are not warranted by the indication of values in sight. We must cautiously feel our way to the deep and use our best judgment in driving ahead or ceasing to expend money when the facts and values exposed will not warrant it. After a mine has been proved in this way, there are but few risks that are not under the control of careful and skilled management. Your product of the precious metals never rots, it is not affected by tariffs or revolutions, it is not depreciated to any considerable extent by competition, nor is it in danger of over production. Your produce is everywhere welcome in the world's markets; every dollar in gold or silver won from the earth is a dollar added to the world's wealth. The miner is, therefore, a creator of wealth. His industry is the only one that actually produces money. The hardy miners of the Republic have actually produced or won from our desert wastes and rocky barren mountains over \$1,500,000,000 within the last twenty-six years. And this is the money with which your banks, ships, railroads, telegraphs, publishing houses and manufacturing industries are established. How, then, can you presume to question the legitimacy, permanency and utility of mining industry, when it must be evident to every student of history and political economy that mining industry is the mother of all other great systems of labor, and the source to which they must all come, for the life force (money) that moves the world along the grand highway of civilization and human progress.

REPORTER STARKS.—It was reported in town last evening that a rich body of ore had been struck in the Pride of the Mountain mine yesterday. We hope that the report will be confirmed, and that the predictions of Professor Stewart as to the future of the mine will be more than realized. As yet the mine is being worked on the surface only, and when depth is attained on the vein it will undoubtedly prove to be one of the most valuable in this part of the State.—Silver State.

SCIENTIFIC PROGRESS.

On Some Recent Operations in Magnetism.

The nature and mode of action of the magnetic force is a question which at present largely engages the attention of physicists.

When a bar is magnetized with a current in one direction, then with a weaker current in the opposite direction, there is an superposition (according to M. Jamin) of two contrary magnetisms, the one deep, the other superficial; and it is the difference that we then observe. He has cited several facts in support of this view of magnetic action. If a closed steel tube, with a steel bar inside, be magnetized with currents of growing intensity, the first and weaker currents do not magnetize the bar; but with a certain force the bar is magnetized, and increasingly, with the force. If the bar be previously magnetized with a direct current, then put in the tube, and the latter magnetized with inverse currents of increasing intensity, the bar retains its (direct) magnetism while the latter currents are weak, but gradually loses it and acquires inverse magnetism, as these increase.

But there is still better evidence. "M. Jamin procured some very homogeneous bars of steel. After magnetizing one of these he put it in dilute sulphuric acid, and examined its condition every half hour. In dissolving the metal, the acid evidently dissolved also the magnetism. If the magnetism were equally distributed throughout the mass, the proportion of its quantity to the thickness should have been constant; but it was not so. It diminished oven to zero. (This method could be used in reference to the first experiment noted above). Again, M. Jamin took a number of bars of different thicknesses, arranged in series, and magnetized them all with currents of increasing strength. So long as the currents were weak, they gave all the bars the same magnetism, because the magnetized layers penetrated in each to a depth less than its total thickness. But with a certain strength of current the thinnest of the bars was saturated; its thickness was then equal to the depth of the layers. With a stronger current the second bar was saturated, and so on; showing that the depth of the layers reached successively the entire thickness of the bars; and that, therefore, it increases with the intensity of the current. It was found, however, that when the thickness of all the bars exceeded a certain limit, all took an equal amount of magnetism, showing that the magnetic layers themselves are limited to this thickness, which they can never exceed.

The limit is very different in different steels; it is very great in those which are soft or annealed; and diminishes with tempering, and as the proportion of the carbonate increases. Some only took a sort of magnetic "varnish" on the surface, which it was impossible to increase in thickness with any intensity of current. But if the depth of the magnetism diminishes when the magnetic conductivity decreases, the intensity of the magnetism goes on increasing.

This remarkable property of magnetism, of concentrating at the surface of very coercive steels, led M. Faye to suggest that perhaps it might be possible to make magnets of thin layers of magnetized steel alternating with thin layers of copper, which would possess an energy and constancy unattainable in continuous masses. And we may note in this connection, that M. Camacho has lately presented to the academy a new form of electro-magnet, giving strong dynamical effects with weak currents, and in which each core is formed of a series of concentric tubes, with insulated copper wire passing round them successively, beginning with the outermost tube of one arm, and terminating with that of the other.

Another question with which M. Jamin has recently been occupied, is the effect produced by application of armatures to perfect magnets. When an armature is applied to one pole, say the north, of a magnet, it does not in any way affect the south portion, that has no armature. If we now apply an armature to the south pole, it can be easily shown that the armature takes the magnetism which the steel loses, but this new distribution is in no way modified if we either detach or attach the armature of the north end. The two halves of the magnet are quite independent with regard to their armatures. Again, it is only a redistribution of magnetism that occurs when an armature is applied; the previous quantity is neither increased nor diminished. It seems from experiments as if the armature gained more than the magnet loses, but the cause of this is the different magnetic conductivity of the steel magnet and of the iron proof-concent with which the strength of the magnet is estimated. The author's investigations lead him to the result, that in combining a number of magnetized bars, the total force obtained will increase with the extent of the armatures. The larger this extent the greater is the number of bars required before the (higher) limit of force is reached.—*Iron.*

THE FLOOR OF THE MISSISSIPPI VALLEY.—The boring of an artesian well at St. Louis showed the Potomac sandstone to be four thousand feet below the head of the Mississippi river; and as this rock carries a fossil *trilobite*, that level at one time must have been the floor of an ocean.

SEA WAVES.—Dr. Scoresby's observations on the height of waves in the North Atlantic Ocean, records twenty-four, thirty and forty-three feet—the latter the highest. The mean of his records was eighteen feet. The highest waves in the Bay of Biscay, as recorded by French observers, is thirty-six feet. Capt. Wilkes records thirty-two feet in the Pacific, and Sir John Ross thirty-two in the South Atlantic. The highest waves observed in N. W. gales off Cape of Good Hope are forty feet; off Cape Horn, thirty-two feet; in the Mediterranean, fourteen feet ten inches; and in the German Ocean, thirteen and one-half feet. In the British waters the waves are found to average only eight or nine feet.

The velocity of ocean storm waves, as observed by Dr. Scoresby in the North Atlantic, was thirty-two miles per hour. Capt. Wilkes records twenty-six and one-half miles in the Pacific. It is claimed that storm waves have been known to traverse at the rate of sixty miles an hour (doubtful authority).

Dr. Scoresby estimated the distance from crest to crest of Atlantic storm waves at 600 feet. From the above the reader may ponder on what small dimensions the most terrific waves are constructed.

CURIOSITIES OF EBULLITION.—Dr. T. L. Phipson, in the *Chemical News*, says that water, strongly acidified with hydrochloric acid, and containing a small quantity of benzole, was found to enter into violent ebullition every sixty seconds; after while the boiling ceased completely, and then recommenced suddenly every thirty seconds for some time. The flask still being kept over the spirit lamp, the periods between quiescence and violent ebullition dropped to twenty, ten, and finally to eight seconds, at which interval the phenomenon continued for some considerable time. The temperature of the vapor in the flask was 214° F., in the liquid 218°, during the whole time of the experiment. When methyl alcohol was added to the above mixture of water, hydrochloric acid and benzole, and the flask placed over a spirit lamp, no ebullition at all occurred for a very long space of time, and then it took place very suddenly and continued.

BURNING IRON.—A Berlin experimenter has demonstrated the combustibility of iron peculiarly. He takes a straight bar magnet of some power, and sprinkles iron filings on one of its poles. These filings arrange themselves in accordance with the lines of magnetic force; and however closely they may appear to be placed, of course no two of the metallic filaments are parallel, and consequently a certain amount of air is enclosed as in a metallic sponge. The flame of any ordinary spirit lamp or gas burner readily ignites the finely divided iron, and it continues to burn brilliantly for some time, the combustion being, apparently, as natural and easy as that of any ordinary substance. If the experimenter with this operation stands on a slight elevation and waves the magnet to and fro while burning, a magnificent rein of fire is said to be produced.

COLORATION OF METALS.—A French correspondent says that if objects in metal are plunged in a bath composed of a solution of 42.5 grammes of acetate of lead in 225 of water, and heated to 88 or 93 deg. Cent., the sulphate of lead is precipitated in flocculent black particles, and colors the metal with a tint of which the density depends on the amount of the precipitate. Care is required, however, in heating the metal regularly, to obtain uniformity in tint. Iron treated in this way assumes the appearance of blued steel; zinc, on the contrary, becomes brown. Sulphuric acid, used in the same proportion as the acetate of lead, will color gun-metal a splendid red, which is very permanent. Imitations of marble are obtained by covering brass heated to 160 deg. Cent. with a solution of lead thickened with gum tragacanth, and afterwards submitted to the acetate of lead bath above mentioned.

THE SUN'S RAYS IN WATER.—A curious experiment has recently been made to ascertain how far the sun can penetrate the water. The research was conducted upon the lake of Geneva, whose waters are among the clearest of the Swiss lakes, and the results have recently been communicated to the Society of Natural Sciences in the canton of Vaud, by M. Forel. He found that the chemical action of the sun's rays was felt in the summer time at the depth of between forty and fifty metres. We are not aware of the nature of the sensitive compound employed in these experiments, but hope shortly to learn more of the details.—*Photographic News.*

Five thousand feet beneath the grand prairies of Illinois is found the Silurian limestone, in which lie imbedded vast families of crustaceans that once sported in the waters of an ocean. Then the edict was promulgated that the ocean should be filled up, and that the face of the land thus formed should blossom with the rose and violet, that the growing grain should wave over the grave of this once active animal life, supporting a dense population of human beings; and it was done. But who shall estimate the cycles that intervene between that epoch and the present?

THE "MISSING LINKS."—Mr. Darwin has in press a description of a few of the "missing links" between animal and vegetable life, in a monograph on carnivorous plants.

MECHANICAL PROGRESS.

Steel Boilers in England.

In his address on taking the chair as President of the British Iron and Steel Institute, Mr. William Menelans, said to be 'perhaps the most practical iron worker in the world,' spoke as follows of English experience with steel boilers. His remarks have a peculiar interest in this country in view of the recent discussion of the Master Mechanics' Association on this subject:

Mr. Sharp, of Bolton, was one of the first to produce excellent boiler and ship plates of steel, and to make boilers of steel plates. Mr. Sharp tells me that they have made between nine and ten thousand tons of steel plates at Bolton, three fourths of which have been used in the construction of boilers. He says that steel plates, with a tensile strength of from thirty to thirty-four tons, are easily and safely worked by experienced men. They have had steel boilers at work for nine years, and they have given perfect satisfaction, and the repairs are light as compared with those of iron boilers.

Mr. Adamson, whose talents as a mechanical engineer are well-known, informs me that in his steam engines, when the choice of materials is left with him, all the principal parts are made of Bessemer steel, and that the results have been most satisfactory. Mr. Adamson states that he has used various kinds of steel in boiler work, but since the introduction of Bessemer steel plates he has used no other; of this material he has made between six and seven hundred boilers, mostly for high pressures. He is now making a number of steel shell and fire-box boilers, of seven feet diameter, to work to eighty pounds and one hundred pounds pressure to the square inch.

He describes his method of working steel plates as follows: "A piece is cut off every plate and tested before the plates are accepted; the edges of the plates, when used for boilers, are all planed, the rivet holes are drilled through both plates together, after the plates are bent and in place; in every case double or chain riveting is adopted." He goes on to say: "In the application of steel plates for fire-boxes, I have experienced the most satisfactory results; there is no blistering, and the plates show great endurance. When boilers have been allowed to run short of water, the plates have bulged or collapsed, but they never fractured." In this respect, he thinks that steel plates are superior to any iron ever made. Mr. Adamson, like Mr. Sharpe, advocates the use of steel of comparatively low tensile strength, from thirty to thirty-two tons per square inch. Steel of thirty-eight to forty tons to the inch was found quite unsuitable for boiler work; it was found wanting in ductility, and the use of such a material was quickly abandoned.

A great deal has been said and written about the want of uniformity in Bessemer steel, but what could be more satisfactory than Mr. Adamson's experience on this head? Messrs. Galloway, of Manchester, who have a large experience in boiler making, and who are noted for the excellence of their work, inform me that when they commenced using Bessemer steel plates, about 1861, the results were not satisfactory, the plates being too hard; but that of late they have used steel plates extensively, and that the conclusion they have come to is, that when the annealing is carefully performed the plates are perfectly trustworthy; in fact, in the testing of boilers they now find quite as little trouble with steel plates as with iron ones, if not less. They state further that careful annealing has a most beneficial effect; and they refer to some experiments made for the Manchester Boiler Insurance Company by Mr. Kirkaldy on the strength of riveted joints, which conclusively proved that even in the case of wrought iron plates which are punched it is advisable to anneal them.

Rapid Corrosion of Iron on Railway Bridges and Depots.

It has frequently been noticed that iron used in railway bridges, which is exposed to the smoke, steam and heated gases escaping from the passing locomotives, shows a greater tendency to corrode than iron in situations not so exposed. In some cases the iron beams and rods on the upper part of the bridge have been found to be rusted to such a depth that the safety of the bridge is endangered. It is therefore important to learn the causes of this rapid corrosion, in order to know what steps must be taken to prevent it.

A few weeks ago some pieces of iron rust, taken from a bridge on the Pennsylvania railroad, were sent to the laboratory of the Stevens Institute, for a qualitative chemical examination, to learn whether such examination would reveal any of the causes of the rusting. The result of the analysis showed that rapid oxidation was undoubtedly caused by the presence of carbonic, sulphuric and sulphurous acid, which are sufficient to promote rapid corrosion whenever present in the smallest appreciable quantities. The sources from which these substances are derived is evidently the escaping gases of the locomotive, which contain carbonic acid, and it there is sulphur in the coal, sulphurous and sulphuric acids. The same difficulty is met with in connection with

railroading in England, as will be observed from the following paragraph, which we clip from the *Industrial Monthly*:

"There would appear to be some danger in the use of cast iron as a roofing material for railway stations. The Vice-President of the Manchester Literary and Philosophical Society exhibited at the last meeting some portion of the cast iron roof from the Salford station of the Lancashire and Yorkshire railway, which having been put up for a period of four years, was so much corroded and damaged that it had to be taken down. He attributed the effects to sulphuric acid and soot, arising from the combustion of the coals used in the locomotives passing under it, aided by the action of steam and vibration. He referred to a paper by himself, communicated to the society, on the effects of old coal-pit water on cast iron, where similar results had been produced by sulphuric acid, carbonaceous matter and water; also to a case alluded to by one of the most distinguished members of the society, the late Dr. W. Henry, of the rotting of cast iron by the escape of steam from the junction of a pipe imbedded in charcoal. Of course, the rate of decomposition much depended on the quality of the iron, but as that metal was now so much employed in building and mining operations, he considered it desirable to bring before the public every instance that came to his knowledge where it had been damaged or decomposed."

Adhesion of Glue.

Mr. Bevan, experimentalizing on the adhesion of glue, fastened together two cylinders of dry ash wood, one-fifth of an inch in diameter and about eight inches long. After they had been glued together twenty-four hours they required a force of 1,260 pounds to separate them; and as the area of the circular ends of the cylinders was 1.76 inch, it follows that a force of 715 pounds would be required to separate one square inch. It is proper to observe that the glue used in this experiment was newly made, and the season very dry; for, in some former experiments on this substance, made in the winter season and upon some glue which had been frequently heated, with occasional additions of glue and water, he obtained a result of 350 to 500 pounds to the square inch. The present experiment was, however, conducted upon a large scale, and with care in the direction of the resultant force; so that it might be as nearly as practicable in a line passing at right angles through the center of the surfaces in contact. The pressure was gradually applied, and was sustained two or three minutes before the separation took place. Upon examining the separated surfaces, the glue appeared very thin, and did not entirely cover the wood, so that the actual adhesion of the glue must be something greater than 715 to the square inch. Upon comparing with this the natural cohesive force, latterly, of wood of the same kind, Mr. Bevan found it to be only 562 pounds; consequently, if two pieces of this wood were well glued together, the wood would have yielded in its substance before the glue. From the subsequent experiments made on solid glue the cohesive force was found to be 4000 pounds per square inch, from which it may be inferred that the application of this substance as a cement is unsceptible of improvement.

COMPRESSION IN CASTING.—Col. Uchatius, director of the Arsenal at Vienna, whose name is coupled with a peculiarly fine and tenacious steel made in Sweden, has lately given the results of an exhaustive series of experiments on compressing bronze when in a state of fusion, and otherwise treating so that it acquired many of the properties of steel. With an alloy of 90 per cent. of copper and 10 per cent. of tin, and a pressure of eighty tons, a very hard, tenacious metal was produced, but one with little more elasticity than ordinary bronze. On cold rolling this bronze cast, under pressure, into an ingot, its power of resistance, its elasticity and hardness were increased. After repeated experiments it was found that an alloy of 92 per cent. of copper and 8 per cent. of tin was the best and most economical. In casting the bronze to produce a homogeneous mass, after repeated and varied trials a double mould with a solid forged copper core 0.05 metre in diameter was decided to be the best. The bronze produced in this manner is declared to have all the hardness, homogeneity, and power of resistance of steel tubes. Its wearing qualities are as great, and the cost of bronze guns made in this way is much less than steel if the value of the old metal is taken into account.

QUERY.—A correspondent of the *Scientific American* propounds the following query: The pressure gage and the safety valve on my boiler do not agree. The steam blows off freely with the weight at eighty pounds on the lever, while the gage shows but sixty. The valve is thirteen-sixteenths of an inch in diameter. I have examined the gage and find nothing wrong. How can I calculate the proper weight for the valve? That journal answers as follows: When you have no steam in the boiler, secure the valve stem to the lever, and attach a spring balance to the lever just over the center of the valve stem. Then raise the lever slightly, so as to get the valve clear of the seat, and note the reading of the spring balance. Then divide this reading by the area of the valve in square inches (0.5184 in your case), and the quotient will be the pressure in pounds per square inch at which the valve opens. The attention of all who wish to test their safety valves is invited to this extremely simple and accurate method.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

MINING.—Amador Ledger, June 12: Our quartz mines are generally looking well, and the ores taken from the various developed mines keep up the usual yield per ton. The mills now being run by water find many advantages resulting from the latter power over steam; more rock can be crushed in a given time by reason of the steadiness of the propelling force and uniformity of motion. All the mills now using steam within reach of the Amador canal are making preparations to run by water.

VOLUNTEER MINE.—The mill now being erected on this mine is progressing rapidly, and in a very short time will be ready for crushing. The mill will have 10 stamps propelled by water. The ore from the mine presents a very flattering appearance.

GOVER MINE.—This mine presents a very fine appearance, indeed. Mr. Reichling and Mr. Berryman say, in regard to their examination of the Gover, "We find a large and well defined quartz ledge, with sufficient ore in sight to supply a 20-stamp mill for many years," again they say, "The rock appears to be of fair quality and contains an unusual quantity of sulphurets, which we are satisfied are good." Mr. Horn says, "He was greatly surprised to find the mine looking so well," and suggests a larger mill, as also an air shaft; with the latter he says there would be no difficulty in taking out 100 tons of ore per day.

There is a strong probability that the Amador canal company will convey water across Amador creek and supply motive power to the Gover and other mills in the vicinity. Mr. Tregloan, the superintendent of the Gover, has worked faithfully and intelligently in developing the mine, and under his management it is fast becoming valuable property. With a larger mill and steady crushing power, the mine would soon become very productive property. We are glad to chronicle the flattering prospects of the Gover.

CALAVERAS.

GOOD CLEAN-UP.—Calaveras Chronicle, June 12: One of the best paying gravel claims in the middle or southern counties is the Tunnel Ridge hydraulic, owned by J. F. Veith, Esq., of this place. The claim is a very extensive one, and it is worked on a large scale. A recent clean-up, after a "run" of fifteen days, yielded \$3,000, and more than the usual quantity of top dirt was washed. The claim is good for an average yield of \$200 for every day water is run. It will better any of the hydraulics in the State, except a few of the most prominent ones in the northern counties, to make a better showing.

WEST POINT DISTRICT.—A "worked out" mine has been relocated by Mr. Woodworth, and is now being reopened. Its location is south of the Josephine. Josephine is turning out 10 tons of ore per 24 hours. The bottom of the shaft shows better ore than ever, yielding very valuable specimens. The "Matrimonial" has been relocated. The Enterprise company are beginning a new working shaft on the main south chimney of the Mina Rica mine. This chimney was worked many years ago to the depth of 175 ft, with handsome profits, in spite of reckless management. The present company intend to erect here their principal hoisting works and sink the shaft to the depth of 500 ft as fast as muscle can accomplish it. The Fields tunnel is turning out very fine ore. The Haskins mine, near Skull flat, yields fine ore which is nearly pure sulphurets. Champion ore rich as usual.

COLUSA.

THE RICHEST YET.—Colusa Sun: A vein of cinnabar about 2 ft thick has been struck in the Rathlum mine, which is perhaps the richest ever found in this State. It is very soft, is pure vermilion, and is about 80 per cent. mercury, the balance sulphur. There is no rock or hard substance in it.

INYO.

PANAMINT ITEMS.—Panamint News, June 8: The southern portion of our district, although first discovered, excited less attention than the Surprise or Narchoe canons, although Happy valley and the canons south are better watered and have more timber than the first mentioned localities. During the past two months Happy valley and the canons lying south have attracted considerable attention by recent discoveries made by experienced prospectors, the most prominent of which are the Pennsylvania, Stonewall Jackson, General Lee, Young America and others, beside the well known Happy Valley and Juno claims. The Pennsylvania, about half a mile south of the Juno, is a gold and silver bearing ledge of high grade, assaying from \$18 to \$20 in gold and from \$30 to \$150 in silver, with small quantities of lead, showing considerable free gold to the naked eye. This ledge consists of three parallel veins about 100 ft apart, with a width of not less than 3 ft, and widening to 5 or 6 ft. But little is done as yet on this claim. The ledge shows more than 400 ft on the surface, and two extensions have been taken up. The same parties have discovered the Stonewall Jackson. This is a carbonate bearing ledge of great strength, showing at no point less than 10 ft, and increasing to a width of 25 and 30 ft. This ledge lies at the

head of Happy valley, running southerly from the foot of Sentinel peak across the valley, continuing in nearly a straight line over the next ridge and across Indian valley, showing over 7,000 ft on the surface. The ore assays from \$18 to \$68 in silver, and is improving as the work progresses. The General Lee is a ledge of the same characteristics as the Stonewall Jackson, apparently a part of the same, and running together at the northern and southern extremities, with a hill between them. At the junction of the two ledges it attains a width of 35 or 40 ft. A heavy body of timber to the south and east, easy of access, with a sufficient quantity of water, combine to make this claim very valuable. To the southward lies the Young America and other claims, showing more of the character of the Surprise canon ledges, all of which are bound to make Happy valley an active and busy camp at no distant period.

FRESNO.

QUICKSILVER MINING.—Fresno Expositor, June 16: From Deo Melcolm, of Panoche, we learn that the Little Panoche mining company is now extracting some very fine ore from the mine, and the work of developing it is going steadily ahead. The Fresno mine, near Mexico, is also developing well. A considerable force of men is engaged at the mine. The New Idria company are working a full force of men, and are turning out an abundance of the silvery liquid. The Cerro Benito mine is looking much better than formerly. A tunnel has been run from the flat into the mountain, a distance of about 1,500 ft, and a fine vein of ore has been struck, giving great encouragement to the owners of the mine. Two new locations have been recorded by John W. C. Maxwell, superintendent of the New Idria mine. They are both situated near the New Idria mines. The prospects are now favorable for a busy mining season in that region, and if the new mines only turn out as well as is now anticipated, the region of country in and around Panoche will be thickly populated and prosperous.

KERN.

HAVILAH MINES.—Southern Californian, June 10: Mr. Jacoby arrived from Kernville on Monday. He gives the most encouraging statement of the mines of the county. The Summer mine, he is led to believe, will yet be able to run a thousand stamps. The owners have a patent for nearly two miles of mineral on the surface with a depth beyond imagination. Since the change of ownership of the mines at Havilah there is strong prospect of great improvement in that section. One good mine would be worth more than all the county seats they could ever hope for. The county seat will not make a town of any place. Too much importance has been attached to it. With good mines, or a large and prosperous agricultural country about it, the town must grow into a city. Without either all would be a failure.

LAKE.

COAL LOCATION.—Santa Rosa Democrat, June 12: On Soda creek, six miles from Grunoe, in Lake county, several localities have been made for coal by different parties. The best prospect so far is on the location of T. H. Hames and James Brown. The last named parties are following down upon a stratum, which at the depth of 40 ft has widened to nearly 10 inches. The quality of the coal is very superior, and there seems scarcely a doubt but that a good coal mine will be developed on this claim. Mr. James Brown formerly lived in Anala township, in this county, and his many friends here will be glad to see him make his "pile" on coal.

NEVADA.

KENTUCKY MINE.—Foothill Tidings, June 12: The contractors are making very good progress in sinking the main shaft of this mine, the ground being quite favorable. The ledge in the bottom of the shaft is somewhat split up but the quartz looks well, the black rock or cab is cutting out and the walls are now taking their regular dip—showing that they are getting down to where the country rock is more settled. No water is met with in sinking. As an indication and to show what practical miners think of Kentucky as an investment, we will mention that a few days since one of the foremen in the Idaho, a most thorough miner and a man of superior judgment, went through the mine and examined it carefully, and so pleased was he, comparing the present aspect of affairs with those of the Idaho at the same depth, that he immediately purchased stock at several times the price at which it was sold a few months since. It is this class of men, men who saw Idaho go up from \$2.50 to \$25 and then to \$250 and since to \$1000 a share, and who know just how that mine came near discouraging its owners before they got down to its permanent and paying levels, that are gradually picking up this stock.

HOWARD HILL MINE.—Grass Valley Union, June 16: In visiting the mine, after examining the upper levels we found ourselves at the 300-ft level. The shaft is 100 ft deeper than this but has not been pumped out as yet. A six-inch pump is in it now, so that when it is thought expedient, it can soon be made dry. The east drift on this level is the only part of the mine that is now being worked, and 6 men are here employed working eight hour shifts. This drift is in 460 ft, which carries it into the Cambridge ground. In the face of this drift the ledge is at least 6 ft thick and as fine a one as we ever set eye on. Plenty of beautiful sulphurets and considerable free gold is visible. The ledge in this drift clear from the shaft has been so large that but little of the foot or hanging walls have had to be removed, hence there is but little dead work. From this

drift alone the dump has been filled, and it has now become a question where to store the rock until the mill commences. The west drift at this level is in 380 ft, and has a good ledge in its face. Stopes enough are now opened to keep the mill running a year with the rock now in sight. The most of the water encountered comes from the Cambridge works, for a large stream constantly flows from it. After a close examination of the ledge in the drifts and stopes, we came to the surface and went through the mill. Fifteen stopes are still in place from the old mill, but the rest of the works have been removed and will be replaced by the very latest improvements. The machinery is being overhauled and fixed up, so that when it is at work a saving of at least two cords of wood per day will be effected. Electro-copper plates and Eureka rubbers will be introduced, and the mill will start in July. It will crush between 35 and 40 tons of rock a day, and the rock will average at the very least \$20 per ton. This average will no doubt fall far below the real yield, but to be safe we say \$20. This can be mined and milled for \$6 per ton, which leaves \$14 a ton clear gain.

PLACER.

MINING ITEMS.—Placer Argus, June 12: The St. Patrick mine is looking up under the efficient management of J. A. Townsend. The 212, 312, 360 and 440-ft levels are showing good milling ore. The clean-up of the St. Patrick mill, on the 3rd inst., proved very satisfactory. Two gold bars, weighing 502 ounces, were shipped to San Francisco, one-half of which was the yield from 64 tons of rock taken from the 440-ft level. It is the intention of the company to shortly put in new machinery for hoisting, the present proving inadequate for the present work.

The Good Friday mining company are drifting and running west at a depth of 120 ft. The rock improves as the work progresses.

The Eclipse mill and mining company have leased their mill to C. A. Cooper, who will continue to run it on custom rock.

The St. Lawrence mill and mining company started up their mill on Monday. They have 100 tons of rock on hand that promise to pay well. They are stoping on the 150 and 175-ft levels. The ledges are from 15 inches to 4 ft in thickness. Isaac Thomas is the superintendent of the mine.

The Kirkland mill and mining company, located near Ophir, on the road between Ophir and Newcastle, is owned by an English company. This is a new company, the ground having been recently surveyed and patent applied for. A mill will be erected at once.

The business prospects of the Green mine are flattering. Everything is looking well. The company intend to put in a new pump to connect with the old one now in use, so that they can sink deeper. The rock of this mine improves as they go down.

The Hobson gravel mining company are pushing their work with considerable energy. They have now about 30 men at work in laying pipe, about 90 Chinamen at work digging ditch, and 6 teams hauling timber and pipe.

The Placer Herald says that most of the mines are still running at Dutch Flat and Gold Run, and those places are livelier than they have been for years. Money there is said to be plenty.

PLUMAS.

GREENVILLE ITEMS.—Cor. Plumas National, June 12: Mining interests are looking up. The Indian Valley mine shipped \$3,000 last week for twenty days' run of sixteen stamps. The Wolf Creek mine, under the new management, is doing finely, and promises to be one of the best paying mines in this section. The Green Mountain is said to be sustaining its former reputation of one of the best on this side of the ridge. The Union mine is running twelve stamps with prospects improving every day. The Baker ledge has its full complement of men and a good body of rock in sight. Harry Gregg is taking some of the richest rock from the Grass ledge that has ever come out of it. Tanner has recently sold his interest in the Corvales ledge to his partner Wiles, for \$2,000.

SANTA BARBARA.

OUR QUICKSILVER MINES.—Santa Barbara Press, June 5: We take pleasure in saying that the cinnabar mines, in this county, are soon to be represented in the market with the first ore smelted in their furnaces. On Monday next, June 7, the first furnace will be fired in the Los Prietos mines, and in a few days the value of these mines will be tested in a practical manner. The company have reason to feel some degree of satisfaction with the work done on these mines. There is no distrust of their richness and value as the ore is accumulated for the fiery trial. Everything about the outlay has been on a broad scale, and the determination to develop the immense resources of these mines to the fullest extent has never flagged for a moment.

SAN BENITO.

CINNABAR AND COAL.—San Benito Enterprise, June 12: It is not generally known that in the last few months the most flattering prospects for extensive cinnabar and coal have been discovered and partially developed, in the district of country between Slack's canon and the head of Cholame valley, lying about 80 miles southwest of Hollister. Some 30 or 40 quicksilver localities have been made, on some of which considerable work has already been done with the most satisfactory results. One mine has 100 tons of first class ore on its dumps. A short distance east of the cinnabar range very prom-

ising coal croppings have been found. The geological formation of the country thereabouts, and other indications known to experienced coal miners, leave no doubt of the existence of large deposits of this mineral in that locality—in fact, the croppings prove to be the genuine article.

STANISLAUS.

QUICKSILVER.—Stanislaus News, June 10: The prospects in the Orestimba quicksilver claim, back of Grayson, in the Coast range of this county, are opening up splendidly. A large body of cinnabar has been struck that readily smelts from 10 to 20 per cent. of pure quicksilver. The ledge is large, well defined, and easily worked. Several other claims have also been located on the same range that promise well.

SOLANO.

QUICKSILVER STRIKE.—Vallejo Independent, June 12: A rich strike of black ore was made on Thursday last in the Loop quicksilver mine on D. N. Hastings' ranch, Benicia. The ledge was uncovered for a space of 15 by 20 ft, and every part is sparkling with the metal. Parties well posted pronounce it the richest of anything yet discovered. A tunnel being run is now in 120 ft; which in 50 ft more will strike the chimney 150 ft below the surface.

TUOLUMNE.

BIG OAK FLAT MINES.—Union Democrat, June 12: The Longfellow quartz claim, formerly known as the Butler claim, at Big Oak Flat, we learn is yielding some very rich rock, some of it more suitable for the mortar than crushing in a mill. Also the mine owned by C. Mormon gives out good rock and is undoubtedly a rich claim. A little capital over among the mines in that vicinity will stand more than a fair chance of securing a profit.

The Nonpareil mine at Deer flat has been successfully opened, the tunnel which was being driven the past three years has drained the mine and connections have been made with all the levels. The ore taken out is of a rich grade. While waiting for machinery the mine is not being worked, over 8,000 tons being already out for milling. Machinery for the mill is now on the way from Oakland, which the superintendent, Mr. Du Pratt thinks, can get in place in the next two or three weeks.

THE CONFIDENCE MINE.—Tuolumne Independent, June 12: Is now working 12 men on the 500 ft level, running north and south. In the south drift they have a white rock with not much in it. In the north drift the walls are from 6 to 10 ft apart, filled with vein matter, 10 to 15 inches of which is very good, showing free gold. They expect the vein to fill in, as usual, as they advance, when it will undoubtedly prove a fine chute. It is contemplated to sink, and a Burleigh drill has been ordered for the purpose.

THE GRIZZLY MINE.—They are down 60 ft, and have struck a new chute in the northern part of the mine, where the vein is about 3 ft in width. It looks splendid and shows free gold plentifully. This is a new chute, never before worked. The chances are favorable for a good mine.

SPRING GULCH MINE.—The vein is looking well in the shaft, 250 ft from the surface, they have struck the vein 6 ft wide on the foot wall, showing free gold, and the prospects are splendid.

Nevada.

WASHOE DISTRICT.

CROWN POINT.—Gold Hill News, June 10: Daily yield, 550 tons, from the old ore producing levels of the mine. The stopes and breasts hold out finely, with plenty of ore in sight for some time to come. Nearly 17,000 tons were extracted last month. Nothing doing at the 1600-ft level. At the 1700 the drift seat for the ledge is being pushed forward steadily; the operations at this level are calculated to also test the merits of the level above. The main incline is being sunk deeper, and is now 40 ft below the 1700-ft level.

LADY BRAYAN.—To-morrow sinking the main ledge will be resumed, the drainage tank at the 350-ft level being completed. This will catch up all flowage of water at and above that point, and prevent its interfering with the sinking of the shaft. It is an evidently wise idea to sink this shaft deeper, as the bottom of it is nearly quite touching the east wall of the vein, and owing to the great width and easterly dip of the vein it will probably pass through 300 ft of it before reaching the west wall.

CONS. VIRGINIA.—Daily yield, 600 tons of ore, from the regular ore producing sections. The stopes and breasts continue looking and yielding splendidly as usual. The connections made between the 1400-ft level and the level below, and between the winze from cross-cut No. 3 at the same level, and the up-rise from cross-cut No. 3 of the California 1500-ft level, mentioned in our last report, operate to immense advantage in giving air circulation and cooling off the hot depths of both mines.

CHOLLAR-POTOSI.—Daily yield 80 tons, assaying about \$32 per ton on the average. The old ore sections are holding out pretty well as yet, and the bullion yield for May footed up nearly \$32,000.

OSPHR.—Daily yield of ore 150 tons, principally from the stopes and breasts of the 1465-ft level, which continue to hold out well and promise much. The connection between the winze sunk below the 1000-ft level and the southwest drift from the east shaft, mentioned in our last week's report, proves of vast benefit in the ventilation and development of the mine. The winze is now being continued down to the 1700-ft level for a similar purpose, following the dip of the vein.

BELOHER.—The repairs to the machinery being completed, the works and everything in and about the mine is running as before, giving the regular yield of 500 tons ore. The ore producing sections are holding out finely, with plenty of good pay ore in sight to last for a long time to come. The mills being well supplied with accumulation of ore during the temporary suspension of work in the mine, run steadily along, and are kept doing so. The main incline is now sunk to the depth of 25 ft below the 1600-ft station, with the bottom in dry, hard rock.

GOULD & CONRAT.—The north drift of the 1700-ft level progresses slowly to its connection with the Best & Belcher south drift, owing to the very hard rock and almost unendurable heat. The south drift from the double winze at the same level, is also slowly progressing under the same disadvantages, but as soon as connection is made with the Best & Belcher, first-rate ventilation will be secured and mining operations very much facilitated.

CALEDONIA.—The new shaft is down a little over 200 ft, and good progress being made, considering the amount of water met with. The drain tunnel, to intersect this shaft 120 ft from the surface, will be completed shortly. Most of the new and powerful machinery for this shaft has arrived on the ground, and the mason work of the foundations is under good headway.

CALIFORNIA.—Cross-cut No. 6, on the 1500 ft level, 100 ft south of the Ophir line, is being driven ahead for the ore vein at a lively rate. It is running in hard porphyry, which blasts well, allowing of very good progress.

HALK & NORCROSS.—The daily ore yield of this mine is limited to but a few tons at present. Active prospecting for new deposits is going ahead, with good promise of success.

BEST & BELOHER.—The main north drift of the 1700-ft level is being advanced at a very good rate, considering the difficulties of the situation, and the tough, hard nature of the rock.

SIERRA NEVADA.—Sinking the shaft goes right straight along as usual, and the prospecting operations in the old upper workings of the mine are pushed ahead energetically without, however, any very good developments in the way of new or paying ore bodies.

COSMOPOLITAN.—Mine is looking splendidly, with plenty of good pay ore in sight, but owing to increase of bad air in the stopes, ore extraction from them is temporarily suspended until the proper air drift connections can be made.

SILVER HILL.—Prospecting operations at the second and third levels going ahead vigorously.

UTAH.—The powerful new hoisting works are being hastened to completion as fast as plenty of men and means will allow. The machinery is among the best on the Comstock, and will be ready to start up in the course of a week or ten days.

JUSTICE.—The face of the north drift at the 800-ft level shows improvement, the vein matter being of a more favorable and promising character.

SECREGATED GOLD HILL.—Cross cutting at the 400-ft level has developed a fine body of \$30 to \$40 ore, and a drift is being pushed east for the well known east ore body or red ledge.

BULLION.—The main south drift from the 1700-ft level of the Imperial is steadily advancing along the west wall of the ore vein, and the cross-cut east from it is still in ore. The quartz body developed at the 800-ft level continues looking finely, and promises to lead to a good ore deposit.

GLOBE CONS.—The material in the face of the main west drift at the 240-ft level is getting somewhat softer, and large seams of quartz gravel are being passed through.

WOODVILLE CONS.—New shaft 368 ft deep today. It has passed vertically through 32 ft of milling ore, and, according to present indications, the west wall is not far off.

BALTIMORE AND AMERICAN FLAT.—Very promising bodies of low grade ore continue to be met with in cross-cutting at the 750-ft level.

JACOB LITTLE CONS.—During the past week the ore developed by the west drift and cross-cuts has shown considerable improvement, and the dump shows an accumulation of it which will pay well under the stamps.

MEXICAN.—The bottom of the winze, below the 1465-ft level, continues in low grade ore, the assays of which run higher than those of last week. The prospects are very encouraging.

ORIGINAL GOLD HILL.—Opening out the ore body in the south drift, and extending the north drift farther north is about the situation in this mine.

SACRAMENTO DISTRICT.

GOLD ROCK.—*Silver State*, June 4.—Doctor Pollard, of Sacramento district, brought specimens of ore from a ledge recently discovered in that district to town yesterday, which are rich in free gold. The ledge from which it was taken is situated about a hundred yards south of the old Limerick mining camp, and if it continues much more similar to the specimens exhibited here, Doc. Pollard will soon be a bloated millionaire.

WHITE PINE DISTRICT.

STARTED UP.—*White Pine News*, June 12: The Eberhardt & Aurora company started up their mill last Sunday evening. Everything about it is in splendid working order, and a very successful run is anticipated.

NEW TUNNEL.—The San Jose mining company, at Egan canon, are making preparations to start an extensive tunnel, for the purpose of draining and working their mine to better advantage. The Burleigh drill will be used, the

mechanery for which is now at the mine and is being put up.

VIRGINIA MINE.—Work on this mine is steadily progressing, and so far with the most flattering results.

CHERRY CREEK.—The Cherry Creek Consolidated M. & M. Co., G. F. Williams superintendent, are having ore from the Exchequer mine worked at the Thompson mill, under the superintendence of Capt. Kimball. It was thought this ore from this mine was too base for mill process, but it has been demonstrated that the ore can be easily worked, and the mill is now turning out some fine bullion.

Arizona.

MINING INTELLIGENCE.—*Arizona Citizen*, June 5: The Papago Indians have for years brought here for sale more or less gold dust, but we never expected that this class of mining would be entered into in this section of country to any extent. Not long ago some very good placer gulches were discovered in the Santa Rita mountains, and since that time old California miners have been dropping in there, and a steadily increasing stream of gold has been coming into Tucson, until now it is becoming a very considerable resource, and every day numbers of people are seen going in that direction with pack animals loaded with provisions and tools.

Fred Hughes brought in last week 7 ounces of gold and says that the next time he comes in he shall have 3 pounds. Mr. Music brought in a handsome lot and says that he is more than paying his expenses and has to pack his dirt some distance. He is preparing for the rains and says when the miners get water they will make from \$10 to \$20 per day. Billy Wood took out in 2 days last week \$25, and all who go there seem to be well pleased with the prospects.

Southwest of Tucson, in what is called the Papago country, there seems to be quite extensive gold fields also, and it is from this section that the Papagos have obtained most of their gold. To give some idea of the gold that is coming into this market, one firm has purchased over \$3000 in dust during the last month.

We were shown this week a nugget about one-half gold and silver, taken from a placer claim of Rea, Smith & Co., just below a fine ledge they have, that assays well in both metals. This is rather a rare combination to be found in placer nuggets, and gives evidence that there is something very pure in the way of both these precious metals near at hand.

We have heard that a new discovery has been made in the Pinal mountains about 10 miles from the Silver King, that bids fair to be as good as that famous mine. We have been unable so far to get any particulars.

In the Truman district work is being pushed on the Georgia mine with satisfactory results; vein from 6 to 8 ft solid, with a fine grain of galena ore. At the Lost mine they are sinking a new shaft.

Tully, Oshea & Co. have been running their smelting furnace this week night and day on good looking copper ore. The pure copper they are running out is good to look at.

Tom Roderick came in on Monday from the Ostrich mine and brought with him \$54 in gold taken from one ton of rock worked in an arrastra. Tom says that there is plenty more of the same sort.

Colorado.

CLEAR CREEK ITEMS.—*Colorado Miner*, June 12: The mines on Democrat are nearly all in good pay and yielding well.

The Pelican and Dives are producing heavily, and turning out immense amounts of ore.

On the Pay Rock Consolidated 65 men are steadily employed, and the mine is in splendid condition.

Work is being steadily pushed forward on the Moore lode, on Sherman mountain. A shaft is being sunk on the vein, showing a good body of ore.

BROADWAY TUNNEL.—This property, on Leavenworth mountain, belonging to the Broadway mining company, working under the direction of John Hanning, is steadily improving as development progresses. The mineral from this mine is very high grade, specimen assays showing a result of 4,577 ounces, or a coin value of \$5,917.60 silver per ton. The ore vein varies from 6 to 10 inches. Next week we are promised the result of mill runs from the mine.

CLEAR CREEK MINING AND IMPROVEMENT CO.—Contracts have been let, and leases given, to develop a part of this company's property on Republican mountain. The Barbara Allen, Dryden, Peru and Cosmos lodes will receive the first attention. Huyett & Co. are working on ore in Everett, and will soon be ready to begin stoping overhead, when the mine has been placed in the proper condition. J. Warren Brown, President of the company, is giving his personal attention to the work of development, and does not intend to allow the rich veins owned by the company to remain unproductive.

THE SPECIE TUNNEL. Brown mountain, under the management of Robert L. Martin as superintendent, is making rapid progress on its way to the Atlantic lode, one of the rich ore channels of Brown mountain. One ton of first-class ore lately taken from the deep shaft on this mine gave a return of \$1,128.40, and one ton of second-class ore gave a return of \$499.20, in silver, coin value, per ton. We give these figures to show that our treasure vaults are yielding their wealth, under the magic touch of labor, the royal jewel of manhood. If the Director of the U. S. mint will locate a branch mint in Denver, the resumption of specie pay-

menta will be only a question of a year, or at the farthest two years. Our mining industry, throughout the whole Territory, has a healthy and vigorous growth.

Idaho.

CONDITION OF THE MINES.—*Idaho Avalanche*, June 12: There is increased activity in mining operations during the past week, and the outlook both here and elsewhere throughout the Territory is favorable. The mills in this vicinity are all in operation, with the exception of the Cosmos, which will be running next week, and will be started on ore from the Illinois Central mine. Several new mining projects are being originated and there are indications of very active business throughout the season in both new and old mines. At the latter and many of the former there is a very large quantity of ore awaiting shipment to the mills. A lively business for the season is promised in the transportation of bullion. Although general indications are favorable for active summer's work, we would state that there is abundance of laborers both here and at South Mountain and the numbers being quite equal to the present demand, we would not advise men to come to this quarter with the expectation that they will get immediate employment. The field is large, but requires further cultivation and development in order to justify any extended emigration in this direction by those who might be hoping to realize immediately from their labors in the mines.

ILLINOIS CENTRAL.—The new assorting houses, car track and ore chute have just been completed in this mine, and active operations are in progress. A very rich quality of ore is now being extracted from the first level stopes.

POORMAN.—The guides are being put in condition for the reception of the new cage in this mine and the work will be completed in a few days. Cross-cutting will soon be commenced and from present indications the ledge promises to be very rich.

MARBOANY.—Good ore to the amount of 30 tons a day is being taken out of this mine and is being worked at the Ellmore mill. Much of it comes from the 8th and 9th level stopes. The 10th and 11th levels are being opened up and are showing a splendid quality of ore.

WAR EAGLE.—Six bars of bullion, valued at \$31,772.94, were shipped from this mine during the past week, being the results from one month's run of the Golden Chariot company's mill.

EMPIRE.—Superintendent Carter reports active work in this mine. The 6th level is being driven north and south; a winze is also being raised from No. 6 to connect with No. 5, and the ore thus far turned out is of unusually good quality.

GOLDEN CHARIOT.—Work on the late discovery ledge and in all parts of the mine continues with unabated activity, and the most favorable results are attending the operations. The entire machinery of the Golden Chariot is working successfully, and large quantities of fine ore are being turned out daily.

SOUTH CHARIOT.—The work in the 9th and 10th level drifts shows a steady improvement in the size of the ledge and the quality of the ore.

Montana.

NINE MILE MINE.—Correspondence *New Northwest*, May 28: I am happy to say that reports from Nine Mile are good. We have every reason to believe that Pilon and his company have struck it very rich—say 50 cts., 75 cts., \$1, \$2 and even \$3 to the pan. Everybody is excited. I think you had better come back. No doubt it will make a large camp and the other creek will pay, if they can get on the streak. In a week or two a large crowd will be there, and anyway there will be lots of chances of every kind for you.

Improved Dry Amalgamator.

Edwin J. Fraser, of this city, has recently patented through the MINING AND SCIENTIFIC Press Patent Agency a machine for subjecting dry pulverized ore to the action of quicksilver, in order to separate and amalgamate the metallic portion, while the lighter or non-metallic portion is carried away. It is equally useful for separating finely divided amalgam after the pulverized ore has been submitted to the dry barrel process of amalgamation.

Inside of a box or tank, having an inlet spout at one end and an outlet spout at the opposite end, is mounted one or more cylinders, upon journals bearing on the sides of the tank or box. Each cylinder extends entirely across inside of the tank, there being a narrow space between the outer rims of each, and each one is provided with a number of buckets. Between each two cylinders is secured a partition or plate, so that its lower edge will dip into the mercury and will be just cleared by the buckets of the first cylinder, while its upper edge extends above the surface of the quicksilver for the purpose hereafter described.

The cylinders and rings are covered with copper, so as to give a large amalgamating surface. The tank will be kept filled with quicksilver, so that the greater portion of each cylinder will move in it, and thus preserve a fresh amalgamated surface. The cylinders are geared together so that the power applied will rotate them simultaneously.

The dry pulverized ore to be amalgamated is fed into one end of the tank by the inlet spout.

As it falls on the surface of the quicksilver, the buckets of the first rotating cylinder will catch it and draw it under the surface of the quicksilver and around with it, so as to transfer it to its opposite side and beyond the accompanying partition. During the passage through the body of quicksilver the particles of ore are brought into direct contact with the mercury and the amalgamated surface of this cylinder and buckets, thus insuring the amalgamation of the particles of metal. As the ore is carried past the lowest point in the revolution of the buckets, the particles which have not become amalgamated will begin to rise on the opposite side of the cylinder, where they will be directed by the partition plate to the surface on the side opposite the first cylinder and within reach of the buckets of the cylinder, which again catch it and repeat the process of submersion in the same manner as above described. This process will be repeated as often as there are cylinders in the tank. The worthless portion of the ore will finally be carried to the surface at the outlet spout, from whence it can be removed. By this means the ore is thoroughly subjected to the action of the quicksilver, and any particles of metal which it contains are amalgamated.

This machine is simple and light, so that it can be easily transported to points where it is impracticable to transport large amalgamating machinery, and such as is usually employed for amalgamating in the wet way. It also offers the advantage of providing a means of amalgamating ores at points where water cannot be obtained.

New Books.

"Designing and Construction of Machine Gearing" is the title of a work which has been laid on our table by A. L. Bancroft & Co. It is intended as a mechanics' and students' guide in the designing and construction of general machine gearing, such as eccentrics, screws, toothed wheels, etc. Considerable space is also given to the drawing of rectilinear and curved surfaces, with practical rules and details. The work is edited by Francis Herbert Joynton, author of "The Metals Used in Construction."

As an index of the contents we give the following titles of chapters: "Of the Eccentric Curves," "Of the Screw," "Of the Construction of Toothed Wheels," "Details and Calculations Connected with Shafts, Pedestals and Pulleys," "A Selection of Geometrical Problems Useful to the Mechanical Draftsman and Designer," "Definitions of Terms Used in Preceding Problems." A large number of drawings are given in the latter end of the book. The work will be a very useful one to aspiring mechanics and students.

We have also received from Bancroft "Navigation, in Theory and Practice," by Hon. Henry Evers, LL.D., Science and Art College, Plymouth, author of "Steam and the Steam Engine," "Nautical Astronomy," etc. The work contains some 260 pages and is intended to give the student, as far as possible, a clear insight into the theory and practice of navigation. The writer says he has endeavored to make the subject as easy, practical and perspicuous as possible by presenting the definitions, illustrations, etc., in every variety of aspect. He has certainly gone into much more minute details than is usually the case in works of this character, and he leaves nothing unexplained. The contents are divided up into the following general heads: "Definitions and Preliminary Illustrations," "The Compass and its Declination," "The Log, Log Line and Log Glass," "Plane Sailing," "Traverse Sailing," "Current Sailing," "The Day's Work," "Parallel Sailing," "Middle Latitude Sailing," "Mercator's Sailing," "Great Circle Sailing," "Sailing to Windward or Plying to Windward," "Oblique and Current Sailing," "Specimens of Government Examination Papers, Etc." The different branches under each of these comprehensive titles are clearly and minutely treated, with full explanations in simple language. Everything is illustrated with various examples, the solutions of which are given. The chapter on great circle sailing is particularly full, and that on oblique and current sailing is in itself a sufficient inducement for any one interested to buy the book.

Another interesting book from Bancroft's is an English work on "Handreiling Out Square to the Plank, without a Falling Mould." The system explained is that discovered and taught at the Mechanics' Institution, Liverpool, by John Jones, staircase builder. The work contains seven large plates of handrails with full instructions for working them, as practiced by the author in London, Liverpool and Manchester. The author states that having, on a certain occasion, more than a thousand feet of handrails to make, he studied how to get the wreaths out with less labor and timber and with more accuracy than cutting them out individually; he then discovered that any wreath could be cut out square from a plank of the same thickness as a circle described round a section of the handrail. All wreaths are cut out square from the plank with square joints, and so accurate are the bevels and joints that the rail may be cleaned up ready for polishing before it leaves the bench. He taught this method at the Mechanics' Institution, Liverpool, to staircase hands in 1847, and since then all whom he has instructed have adopted it to the rejection of other methods. This work is a handsome one, well printed on good paper.

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Sixteenth Lecture Delivered before the University of California College of Agriculture, on Wednesday, February 10th, by Prof. C. E. BESSEY.

Transmission of Forms.

It has been advanced by some breeders that the male transmitted certain characters mainly relating to the exterior of the animal, while the female transmitted characters relating to the interior. And there are many cases which seem to admit of such a theory. The color of the cock is usually transmitted to his offspring; the ram transmits his peculiarities of horns and fleece, and the bull the presence or absence of horns. These facts, for such they seem to be, can, however, be explained equally well in another way.

Of Prepotency.

If we cross a number of varieties, we find that instead of the offspring always showing a blending of the characters of both parents, in many cases the young animal or plant more nearly resembles one parent than the other; that is, one parent has transmitted more characters than the other, or has transmitted them with more force.

Thus, when crossing the short-horn bull upon the native cow, the grade offspring is more of a short-horn in its characteristics than it is a native. We say, in this case, that the short-horn bull is prepotent, and to this power of transmission we apply the term prepotency. Now, prepotency may belong to either parent, in fact, it may belong to both parents. The sire may be prepotent, so far as certain characters go, but the dam may be prepotent in other characters. Now, this prepotency tends to give uniformity or fixedness to a race or breed. Darwin makes the observation that in certain families the effect of the prepotency of some ancestor is seen in some distinctive character. He says, "It would appear that in certain families some one ancestor, and after him others in the same family, must have had great power in transmitting their likeness through the male line; for we cannot otherwise understand how the same features should be so often transmitted after marriage with various females, as has been the case with the Austrian emperors, and as formerly occurred in certain Roman families with their mental qualities. The famous bull Favorite is believed to have had a prepotent influence upon the short-horn race. It has always been observed with English racers that certain mares have generally transmitted their own character; whilst other mares of equally pure blood have showed the character of the sire to prevail." Now, this prepotency may come into action independently of any supposed influence of long breeding—so that it cannot be referred to habit, as some would have it. Some of Darwin's examples are interesting and instructive. In chapter fourteen of his work on the variation of animals and plants, he says: "The truth of the principle of prepotency comes out more clearly when certain races are crossed. The improved short-horn, notwithstanding that the breed is comparatively a modern race, are generally acknowledged to possess great power in impressing their likeness on all other breeds, and it is chiefly in consequence of this power that they are so highly valued. Godine has given a curious case of a goat-like breed of sheep from the Cape of Good Hope, a ram from which produced offspring hardly to be distinguished from himself when crossed with ewes of twelve other breeds; but two of the half-breed ewes, when put to a merino ram, produced lambs closely resembling the merino breed."

Here, in the first place, the goat-like ram was prepotent, but his offspring, when mated with as strong a breed as the merinos, were not able to transmit their characters. It is also on record that of two races of French sheep, the ewes of one, when crossed during successive generations with merino rams, yielded up their characters far sooner than the ewes of the other. In other words, the prepotency of the merino rams was greater in the one case than in the other; which necessitates this conclusion, that prepotency is the excess of the power of transmission which one parent has over the other. It is evident that each parent tends, with a certain force, to transmit its characters, and it will transmit them unless the force is met by one superior to it. It is simply a matching of force against force, the stronger force winning here as elsewhere.

Referring again to the examples given by Darwin. In South America there is a breed of cattle called the *Niata* breed, with certain marked peculiarities. "When these are crossed with common cattle, though the *Niata* breed is prepotent whether males or females are used, yet the prepotency is strongest in the female line. In making reciprocal crosses of *pouter* and *fantail* pigeons, the *pouter* seems to be prepotent, through both sexes, over the *fantail*." These examples will perhaps be sufficient to show that the transmission of peculiar character is due to some power or force in one or the other of the parents, and not that one parent invariably transmits certain characters and the other certain others.

In plants, prepotency holds as fully as in animals. "When *Nicotiana paniculata*, a hardy annual species from Peru (three feet high) and *N. vincoflora*, (a smaller, two feet high, tender perennial species, also from South America) are crossed, the character of *paniculata* is almost completely lost in the hybrid; but if *N. quadrivalvis* (a still smaller, one and one-half feet, North American hardy annual) be crossed with *N. vincoflora*, this latter species, which was so prepotent before, now in its turn almost disappears under the power of *N. quadrivalvis*. In this case, evidently *vincoflora* possesses more of this force of transmission than *paniculata*, hence it is prepotent, but *quadrivalvis*, possessing more of this force, is prepotent over *vincoflora*. It would be interesting to know what would be the result of a cross between *paniculata* and *quadrivalvis*. Another case in plants shows well the prepotency one form may have over another and how this influence may last for a long period of time. Mr. Darwin fertilized a purple sweet pea (*Lathyrus*) with the pollen of the Painted Lady sweet pea. The greater number of hybrids almost exactly resembled the Painted Lady variety and this resemblance continued in grandchildren and great-grandchildren—though the later generations showed more and more of the purple color of the other ancestor.

Intercrossing.

It appears to be a plan of nature, in both the animal and vegetable kingdom, that in fertilization, the sexual cells shall come from different organisms. The various arrangements in orchideaceous plants are the most well-known examples of this, but it is now known that in many other orders of plants simpler, but equally effective means are provided for securing cross-fertilization, and it is the opinion of the best vegetable physiologists that this cross-fertilization is the rule, and that cases of continual or habitual self-fertilization are quite rare. In the higher animals, the individuals are divided into two groups—in the one, the male sexual cells are developed—in the other, the female cells. The result of a fertilization in such a case must always be a sort of cross—each animal possessing its individual peculiarities. In the lower forms, where both kinds of sexual organs are found in the same individual, it might be supposed that no such cross-fertilization existed, but even here it is found that fertilization takes place by the congress of two of these hermaphrodite individuals—each fertilizing the other.

(To be Continued.)

Mexican Mines.

A correspondent of the *Chronicle*, who has just returned from Mexico, furnishes the following interesting news from that republic:

The silver mines in the State of Sinaloa, as well as in the adjacent States, are yielding better now than they have done at any time since the early days of mining on the Pacific coast of Mexico, when the mines were worked chiefly by European Spaniards. Many of their old abandoned mines are being worked by Americans, with very profitable results, and I confidently believe that no other country offers such abundant opportunities for profitable enterprise to the experienced miner who possesses a little capital. But there is not much probability that many Californians or others will undertake mining in Mexico whilst such exaggerated opinions prevail in this country and elsewhere regarding the danger to life and property there. The country got a bad name from the experiences of many Californians and others during a very disturbed and disorganized state of the country, and very naturally there is a want of confidence in the Government and a prejudice against the people. I allude to the period of

The French Invasion.

When the disturbances extended even to the mining districts. Prior to that time the local revolutions, or "Pronunciamentos," very rarely extended beyond the agricultural districts and large towns, mining not being interrupted or impeded in any way. And incredible as it may seem, the miner is as safe in his life and property in the mining districts of the Pacific coast of Mexico at the present time as he would be in California or the adjacent States and Territories. Of the mines which are now yielding profitably, there is the "Refugio," in Lower California; the "Tajo," the "Conato Senores," the "Alacran," and the "Gnada-lupe de los Reyes," in the State of Sinaloa; the "Balopitis" mine in the State of Chihuahua, and the "Promontorio" near Alamo in the State of Sonora. The latter mine is being worked on a large scale by an English company, and it is said to be paying very well. Besides the large amounts of silver bullion extracted at the company's "hacienda" they ship large quantities of ore to England which contain both silver and copper. Besides the mines which I have named—and which are owned chiefly by the Americans—there are many other valuable mines owned by Mexicans; also, many of inferior note, which are paying well, with good prospects ahead. It is a significant fact that the mills throughout the mining districts are doing well, and that much of their gains arise from "custom work," which they get from miners who are not able to erect mills of their own. There are now

Two Foundries and a Large Machine Shop at Mazatlan, where mining machinery is made,

in addition to what is ordered from here, indicating pretty clearly that there must be some activity in mining enterprises. Some of the silver bullion is shipped direct to Europe via Panama. The copper mines near Mulege in Lower California are said to be yielding profitably. The shipments of merchandise from this port to Mexican ports of the Pacific have increased of late, and there is good reason to believe that there will continue to be yearly accessions to the business. Many articles of American manufacture (hardware especially) are now being used in place of those of European manufacture. The consumption of the products of California is steadily increasing, some of which are mining powder, fuse, wine, fruit, vegetables, etc. Besides there is always a demand for foreign goods from the bonded warehouses of this city. Mazatlan, which is the principal Mexican port on the Pacific coast, has lost much of its commercial importance of late years, as many drawbacks have occurred to more than counterbalance the mining prosperity. The first of these was the French invasion and the consequent disorganized and revolutionary state of the country during and for some time subsequent to that period. Then the completion of the railroad from Vera Cruz to the City of Mexico, and the construction of good wagon roads from the latter place to such large interior towns as Durango and Guadalupe, causing a diversion of a large amount of commerce from Mazatlan to the City of Mexico. Thence the

Removal of the Seat of Government

From Mazatlan to Orlizacan, together with the emigration of many families from Mazatlan and vicinity to Tepic and adjacent country after

Stevens' Patent Lamp.

the capture and execution of the celebrated and much dreaded Indian, Lozada, who had held despotic sway over that portion of the State of Jalisco for some fifteen years in defiance of the Federal government. The Mexican government is evidently becoming stronger of late, as evinced by the increased strength and efficiency of her army. This improvement may be traceable to the circumstance that of late years there has been no evasion of the payment of full duties by European importers. But if a leak has been stopped in this direction, it is now breaking out in another, as by all accounts a large amount of contraband is now being carried on, especially on the Atlantic coast. This is the natural result of the unwise policy of Mexican legislators who have offered a premium for smuggling by a ridiculously high tariff on many articles of merchandise.

STRANGE PHENOMENA.—Mr. Braham recently exhibited the following to the London Chemical Society: He exhausted a glass receiver, and, after allowing the air to re-enter through a large opening until equilibrium was restored, he closed the opening and connected the vessel with a pressure gauge. In the course of a minute the mercury now rose one inch. A converse experiment was made by pumping air into a glass vessel, allowing it to escape, and then closing the opening. In a short time there was an appreciable pressure again within the vessel. The assembled chemists offered different modes of explanation of these phenomena, proving them to be in need of investigation, to prove what was true.

A MINER just in from Star City reports to the *Silver State*, the Sheba mine as looking splendidly. The developments in this mine are now of sufficient extent to justify the erection of hoisting works, which will be built immediately.

Stevens' Patent Lamp.

The accompanying cut represents a new improved library lamp, which is designed to meet a demand for an ornamental hanging lamp, adapted to both high and low ceilings, which gives a full reflection of the light upon the table or desk, and at a price that brings it within the means of the mass of housekeepers.

This lamp can be suspended from the ceiling to any desired height from the table, by lengthening or shortening the chains that connect the frame to the yoke.

The light is reflected by a fourteen-inch porcelain shade, which is held by a ring at the top, so that the full power of the light is thrown upon the table, thus obviating the dark shadows cast when supported from the bottom, as is the case in ordinary lamps.

The fount can be taken out of the cup without removing the shade. These lamps are furnished in French bronze, verde antique, Etruscan or extra gilt. It consumes no more oil than an ordinary kerosene lamp, while the inventor claims that it gives double the amount of light. An extension spring is furnished with the lamp when desired, by means of which the lamp can be raised or lowered at pleasure. The inventor is Elisha Stevens, of Cromwell, Connecticut.

What it Will Amount To.

Few people have an idea, unless they have had occasion to look into the matter, of the sum to which a regular saving, however small, each day will amount to in a term of years when invested at compound interest. The following table shows what would be the result at the end of fifty years, by saving a certain amount each day, and putting it at interest at the low rate of six per cent.

Daily saving.	The result.
One cent.....	\$ 950 00
Ten cents.....	9,504 00
Twenty cents.....	19,008 00
Thirty cents.....	28,512 00
Forty cents.....	38,016 00
Fifty cents.....	47,520 00
Sixty cents.....	57,024 00
Seventy cents.....	66,528 00
Eighty cents.....	76,032 00
Ninety cents.....	85,536 00
One dollar.....	95,040 00
Five Dollars.....	475,200 00

At the average rate of interest paid by our California savings banks, these sums would be nearly doubled. This table is worthy of careful study. It conveys a very important lesson to everybody, and especially to the young men of the present age.

NEW PROCESS FOR TELLURIDE ORES.—A. M. Rouse is the inventor and maker of works for the treatment of tellurium ore, just constructed, on a small scale, at Austin Smith's Novelty mills, in this town. It is now ready to go into operation and test its adaptation to the Sunshine ores by breaking the affinity between the tellurium and the other metals. The process includes crushing, roasting, pulverizing in water, by ball mill, and amalgamation at three different points. One hundred pounds of quicksilver is in use constantly, and no stopping for cleaning up. Canon coal is used, costing, laid down at the mill, \$9.50 per ton, by the car load. Nerie Valle is the capitalist of the concern; and the capacity of the works being only from one to two tons per day, no ores will be treated except those belonging to him. He is an owner in the Charcoal and Excelsior mines at Sunshine, than which there are none better. If the process is a success larger works will be erected, and the public become sharers in the benefit.—*San Juan Reporter*.

ANTIQUITY OF IRON.—At a recent meeting of the Philosophical Society of Glasgow, Dr. Ferguson, the President, took occasion to refer to the recent discoveries of archaeological records and remains of Egypt, Mesopotamia, China and India, and concluded by maintaining that abundant proof existed that in the remotest time to which inquiry extended, the inhabitants were familiar with the use of iron and steel; that there was not a trace of evidence of a stone age, still less of a bronze and iron age following; and that it was evident the stone, bronze and iron theory must be sent to the limbo of false and exploded notions.

WHAT BECOMES OF DRIFT COAL.—Dr. Kane, in his arctic explorations, found beds of lignite, or brown coal, that were smoldering along their edges, having evidently been fired by spontaneous combustion; which leads to the deduction that the coal along the line of anticlinal axes of the Mississippi valley coal fields was consumed at the abscission of the valleys of the Ohio, Masoni, and Mississippi commenced and the coal veins were exposed; that these, fired by spontaneous combustion, smoldered as the cutting down of these valleys progressed.

M. PELIGOT, a clever French chemist, claims to have discovered the lost art of producing the beautiful shade of blue which is so conspicuous in many of the ancient ornaments found in Egypt. He analyzed some of the enamel, and then by synthetical experiments has succeeded in ascertaining the proportion of silica, oxide of copper, lime and soda that will produce the marvellous compound.

USEFUL INFORMATION.

Cheap Amethysts.

There is no necessity of wearing violet colored pieces of glass made to imitate smethyst jewelry, as the genuine article is now quite cheap. The large number of amethysts that have been thrown into the market since 1872, from Brazil, has caused a great depression in their value. The first lots sent to Europe brought from \$500 to \$600 per arroba, of thirty two pounds weight; but as the quantity increased the price rapidly receded, and finally decreased to absolutely nothing. At present no offer can be obtained for any lots on hand.

The glass imitation loses its polish very soon, and this shows its utter worthlessness, while the real article, consisting as it does of quartz crystals colored by manganese, is so hard that it will never lose its polish.

Perhaps some of our readers would like to know how to recognize the genuine from the imitation: look at the stone through a magnifying glass, and if you see the least air bubble, it is glass. No real gem of whatever kind ever shows an air bubble. If there is no air bubble, it may be taken as genuine. However as there are sometimes small pieces of glass without air bubbles, a decisive test is necessary. This consists in the use of a piece of an old file: if this will scratch the gem it is glass, if it does not scratch it, it is amethyst, as this is harder than steel, while glass is always softer.

BOYTON'S LIFE SAVING DRESS.—The inventor of the life-saving dress recently so successfully tested by Captain Paul Boyton is M. C. S. Merrimen, of New York City. It is of solid vulcanized rubber made in two parts—a tunic with hood and gloves attached, and pantaloons with boots attached. The dress is secured by a water tight joint at the waist and only the eyes, mouth and nose are exposed. It is inflated by means of five small tubes, which can be reached conveniently. When the upper chamber is inflated it makes a complete air pillow, upon which the head can rest. The wearer is kept dry and comfortable. Swimming is impossible; but he lies easily upon his back, and propels himself in any direction by means of a double-bladed paddle. A small India rubber bag contains provisions and a few needful articles.

UTILIZING OLD RUBBER.—A new industry has just sprung up in Northborough, Mass. Old rubber boots, shoes, blankets, etc., are collected, ground up and manufactured into cloth. In connection with the above we clip the following from the query column of the *Scientific American*: A young man has lately experimented on vulcanized rubber (old shoes, etc.), and has obtained (by the action of certain reagents) several substances of different colors. I send you samples of five of those colors. What do you think about them? Ans: May not the colors be due to the substances put in, and not to the bodies gotten out by the various reagents? For example, the brilliant yellow color on examination proved to be chromate of lead, which certainly does not exist in old rubber shoes.

PLATING WITH ALUMINUM.—According to John A. Jeancon, of Newport, Ky., metal surfaces may be plated with aluminum by the following process with great facility: Dissolve any desired quantity of a salt of aluminum, such as the sulphate, muriate, nitrate, acetate, cyanide, etc., in distilled water, and concentrate the solution to 20° Baumé, (at 50° Fahrenheit) in a suitable vessel to hold the article to be plated. The battery to be used should either be four pairs of Smee's zinc-platinum, or three of Bunsen's zinc-carbon, with the elements connected for intensity, and a plate of aluminum attached to the negative wire. The solution should be slightly acidulated with its appropriate acid, heated to 140° Fahrenheit, and kept at that temperature during the operation.

TO REMOVE A TIGHT FINGER-RING.—In case a finger-ring becomes too tight to pass the joint of the finger, the finger should be first held in cold water to reduce any swelling or inflammation. Then wrap a rag soaked in hot water around the ring to expand the metal, and lastly soak the finger. A needle threaded with strong silk can then be passed between the ring and finger, and a person holding the two ends and pulling the silk, while sliding it around the periphery of the ring, will remove the latter. Another method is to pass a piece of sewing silk under the ring, and wind the thread in pretty close spirals and closely around the finger to the end—that below the ring—and begin unwinding.

UNITING GLASS TO IRON.—The invention of Mr. J. Hartley, of Ormskirk, consists in the uniting glass to iron and other materials by means of a preparation named glazune, in order to render glass available for various general useful purposes in which it has not hitherto been employed, by a process of supplying it with uniform attachment to and support by the iron and other materials to which it may be united, and thereby reducing its liability to fracture when subject to pressure and concussion, and entirely removing its liability to conchoidal fracture.

AQUA-PORTIS, applied to the surface of steel, produces a black spot; on iron the metal remains clean.

FOR THE HENSES.—A patent has recently been granted for a method of refreshing horses while in harness, which consists in making this bit hollow, and having perforations in it. A rubber tube extends from one side of the bit to the carriage, and by pressing a rubber bag which contains water, the driver is enabled to refresh his horse whenever he chooses without stopping. For saddle horses the water bag is suspended from the horse's neck, or upon the pomel of this saddle.

TO CLEAN GOLD CHAINS.—Put this chain in a small glass bottle with warm water, a little tooth powder and some soap. Cork the bottle and shake it for a minute violently. The friction against the glass polishes the gold, and the soap and chalk extract every particle of dirt and grease from the interstices of a chain of the most intricate pattern; rinse it in clear cold water, wipe with a towel, and the polish will surprise you.

A GELATINOUS substance frequently forms in sponges after prolonged use in water. A weak solution of permanganate of potassa will remove it. The brown stain caused by the chemical can be got rid of by soaking in very dilute muriatic acid.

ABOUT VINEGAR.—It was an observation made by Soehle, but the fact has recently been published as a new discovery, that ordinary brown vinegar will keep bright and clear for any length of time if heated to the boiling point for a few minutes.

Next year will be our centennial. The Japanese have already celebrated their 2535th anniversary.

GOOD HEALTH.

Dyspepsia Foreshadowed.

To be able to sit down to a well-spread table and eat to one's satisfaction three times a day, without any discomfort whatever beyond that of hunger, with a good appetite when the next time for eating arrives, is a blessing and a happiness; and yet there are multitudes, apparently in good health, who have not known what it is for years to take a single meal without its being followed in an hour or two, or more, with torments, actual torments, enough to make a wise man mad; torments which subvert the whole character, souring the heart, embittering the temper, destroying confidence, and turning the sweetest affections into worm-wood and gall. A character naturally placid grows petulant and irritable; the loving heart becomes estranged by groundless suspicions; the cheery face is changed into oppressive sadness, while all that is glad and joyous and hopeful goes out at length in the night of melancholy, despair or suicide. Many a household once happy has become a very pandemonium; the husband a tyrant, the wife a perfect virago and an unendurable shrew.

Such are some of the influences which a diseased stomach has on the mind, temper and the heart. Multitudes of suicides are caused by dyspeptic disease. "Cross" people, the ill-natured, those who are always growing or complaining of something or somebody; inveterate fault finders, upon whose face a genial smile never played, whose hearts are strangers to the humanizing influence of warm sympathies, who have no forbearance, no allowances, no consideration, no love, many such are not thus by nature, but have been molded into wretched "forms" like these by the slow influences of insidious disease, brought on by self-indulgence and unrestraint in the matter of eating and drinking; not deliberately always, but generally perhaps, unconsciously, or in ignorance. These things being so, no rational mind can fail to feel that it is a wisdom and a duty to guard against the causes, and watch vigilantly against the indications which induce and accompany the formation of a disease which is thus capable of subverting the whole character, and making a wreck of happiness and heart and life together.

The almost universal cause of dyspepsia is eating too often, too fast, and too much. The general rule should be:

1. Eat thrice a day.
2. Not an atom between meals.
3. Nothing after two o'clock, but a piece of cold bread and butter and one cup of hot drink.
4. Spend half an hour at least in taking each meal.
5. Cut up all meats and hard food in pease-sized pieces.
6. Never eat enough to cause the slightest uncomfortable sensation afterward.
7. Never work or study hard within half an hour of eating.

The most universal and infallible indication that a person is becoming dyspeptic, is some uncomfortable sensation coming on uniformly, sooner or later, after each meal, whether that be in the stomach, throat or anywhere else. The formation of wind in the stomach, indicated by eructation, belchings, or otherwise, demonstrates that dyspepsia is fixing itself in the system. Then there is only one course to pursue, and that is infallible: eat less and less at each meal, until no wind is generated and no other uncomfortable sensation is experienced in any part of the body. No medicine ever cured confirmed dyspepsia; eating plain food regularly and living out of doors industriously, will cure most cases.—*Hall's Journal*.

Rest.

Multitudes of earth's toiling millions have died while striving to make enough money to retire from business, and in a beautiful cottage on their own little farm to spend the remnant of their days in rest, in having nothing in particular to do. Perhaps one in a million of the hoppers does make money enough to enable him to retire to his country seat, and for a year or two, while he is fixing it up to his notion, all goes on charmingly, but when everything is completed to his mind and he has nothing more to take up his attention, he eats and sleeps and lounges around for a few months longer, falls into disease and dies; or if he has unusual force of character and power of endurance, he notices that both health and happiness are passing from him, and treading this to the true cause of an inactive body and an unoccupied mind, he resolves to "sell out" and plunge again into the vortex of business.

Recently an old schoolmate—yonder, graduating in the same class thirty-seven years ago—writes that "both body and mind are worn out; the slightest physical labor exhausts him," and, "any effort to think or study or even read, so wears the brain that life is felt as a burden." He withdrew from his professional duties, which he had performed in the place for twenty-five years, with honor to himself, having secured the love and confidence and respect of all who knew him. He gave up his calling for the purpose of obtaining rest, as a means of health.

The number of families is increasing every day, who give up housekeeping as a means of rest from family cares, and resort to that miserable and most unwise mode of life, boarding at a hotel or in some private family, to get more dissatisfied than ever in a few months, meanwhile falling into bad health and bad habits of various kinds.

All these classes of persons fail, miserably fail in their object, because they mistake the physiological meaning of the word "rest." Neither body nor brain are safely, truly and happily rested by doing nothing. The only healthful rest, as long as our physical and mental constitution remains as it is, is to be busy. Men of force and industry will everywhere tell you, "It is the hardest thing in the world to do nothing." No mortal man was ever made to be a loafer, to be a miserable drone. The true idea of rest is recreation, a making over again, a return to our accustomed vigor; and this is accomplished, not by allowing the machine to come to a standstill, for inactivity is rust and ruin to all mechanical contrivances, and death to all physiological structures. The true object of rest is recuperation, and that is best brought about as to the body, by exercising a different set of muscles; and as to the brain by calling into requisition a different set of organs and powers, causing the mind to act upon new objects. A better plan is not to get into the unhealthy conditions named, and they are avoidable by giving two hours daily to the exercise of a different class of muscles or to the investigation and study of objects of comparatively trivial importance and of a wholly different nature. The student should ride on horseback, or cultivate fruit and flowers; the merchant should employ his mind in liberal studies, in active personal and elevating charities, while the over-taxed and worried wife should pay a visit daily to some prudent friend, some cheery neighbor or suffering sister or child; the men in all cases being to spend two or three hours daily in open air activities wholly differing from the ordinary business routine.—*Watchman and Reflector*.

Unhealthy Foundations.

Dwellings built on solid and close foundations are always unhealthy. An instance is recorded of a locality in Illinois, where there were three settlements within visiting distance of each other, altogether containing about thirty families. One fall every family of the three settlements (with one exception) was sick with the prevailing fever of the season. The excepted household had an upper floor to their house (a half story) which was used for sleeping in by all the family, consisting of parents, three children and a workman, and they all escaped the fever. All the rest of the inhabitants lived in one story houses, and of course slept and kept all the stores on one floor. In a house with a close solid foundation, we found that things would mold if left standing for a few days. Preserves, placed upon a top shelf, in a short time became moldy; but when placed in the second story they all kept well. A barrel of flour was left standing on the floor; when it was about two-thirds used, the sponge failed to rise, and as a consequence we lost two bakings of bread, it not being fit to eat. The barrel and flour were then taken out of doors and placed in the sun, so that the air could circulate freely around and under it, and after standing thus about six hours, it was replaced on the floor and set on two strips of boards one inch thick. By this means the flour was wholly restored and rendered good to the last. I could cite many other instances.

All receptacles for foul air under or near a dwelling should be very closely attended to, and so opened as to be thoroughly ventilated, as the instances cited very fully illustrate.

DOMESTIC ECONOMY.

How to Remove Spots and Stains from Woven Fabrics.

Taking out grass and other spots from clothes is an application of chemistry which has a practical interest for everybody. It demands a certain acquaintance with solvents and reagents, even though we may not understand the laws of chemical affinity on which their action depends. The general principle is the applying to the spot a substance which has a stronger affinity for the matter composing it than this has for the cloth, and which shall render it soluble in some liquid so that it can be washed out. At the same time it must be something that will not injure the texture of the fabric or change its color. The practical hints we shall give are condensed from a variety of foreign sources.

The best substances for removing grease or oil are: 1. Soap. 2. Chalk, fuller's-earth, eteate or "French chalk." These should be merely diffused through a little water to form a thin paste, which is spread upon the spot, allowed to dry, and then brushed out. 3. Ox-gall and yolk of egg, which have the property of dissolving fatty bodies without affecting perceptibly the texture or colors of cloth. The ox-gall should be purified, to prevent its greenish tint from degrading the brilliancy of dyed stuffs, or the purity of whites. Thus prepared it is the most effective of all substances known for removing this kind of stains, especially for woolen cloths. It is to be diffused through its own bulk of water, applied to the spots, rubbed well into them with the hands till they disappear, after which the stuff is to be washed with soft water. 4. The volatile oil of turpentine. This will take out only recent stains; for which purpose it ought to be previously purified by distillation over quicklime.

An earthy compound for removing grease spots is made as follows: Take fuller's-earth, free from all gritty matter; mix with half a pound of the earth, so prepared, half a pound of soda, as much soap, and eight yolks of eggs well beaten up with half a pound of purified ox-gall. The whole must be carefully triturated upon a porphyry slab; the soda with the soap in the same manner as colors are ground, mixing in gradually the eggs and the ox-gall previously beaten together. Incorporate next the soft earth by slow degrees, till a uniform thick paste be formed, which should be made into balls or cakes of a convenient size, and laid out to dry. A little of this detergent being scraped off with a knife, made into a paste with water, and applied to the stain, will remove it.

Tar and pitch produce stains easily removed by successive applications of spirits of turpentine, coal tar, naphtha, and benzine. If they are very old and hard, it is well to soften them by lightly rubbing with a pledget of wool dipped in good olive oil. The softened mass will then easily yield to the action of the other solvents. Resins, varnishes, and sealing wax may be removed by warming and applying strong alcohol. Care must always be taken that, in rubbing the material to remove the stains, the friction shall be applied the way of the stuff, and not indifferently backwards and forwards.

Most fruits yield juices which, owing to the acid they contain, permanently injure the tone of the dye; but the greater part may be removed without leaving a stain, if the spot be rinsed in cold water in which a few drops of aqua ammonia have been placed, before the spot has dried. Wine stains on white materials may be removed by rinsing with cold water, applying locally a weak solution of chloride of lime, and again rinsing in an abundance of water. Some fruit stains yield only to soaping with the hand, followed by fmnigation with sulphurous acid; but the latter process is inadmissible with certain colored stuffs. If delicate colors are injured by sopsy or alkaline matters, the stains must be treated with colorless vinegar of moderate strength.

Fresh ink and the soluble salts of iron produce stains which, if allowed to dry, and especially if afterwards the material has been washed, are difficult to extract without injury to the ground. When fresh, such stains yield rapidly to a treatment with moistened cream of tartar, aided by a little friction, if the material or color is delicate. If the ground be white, oxalic acid, employed in the form of a concentrated aqueous solution, will effectually remove fresh iron stains. Acids produce red or other stains on the vegetable colors, except indigo. If the acid has not been strong enough to destroy the material, and the stains are fresh, the color may generally be restored by repeated soakings in dilute liquor ammonia, applied as locally as possible. Photogreppers frequently stain their clothes with nitrate of silver. The immediate and repeated application of a very weak solution of cyanide of potassium (accompanied by thorough rinsings in clean water) will generally remove these without injury to the colors.

CREAM APPLE PUDDING.—Take a deep tin pudding dish and cover it with a layer of the best pie crust. Have some good, tender apples cut fine and spread over the paste a layer of apples, with sufficient sugar for sweetening, and cinnamon and nutmeg to taste; again a layer of apples, etc., until your dish is filled, when you pour over it a teaspoonful of cream, add your cover and bake to a light brown.

ding, 399.

MINING STOCK MARKET.—Sales at the San
Francisco Stock Board; Notices of Assessments;
Meetings and Dividends; Review of the Stock Mar-
ket for the Week, 404.

MISCELLANEOUS.—Reported Strike, 394. Mex-
ican Mines; Strange Phenomena; Stevens' Patent
Lamp; What it Will Amount To; New Process for
Telluride Ores; Antiquity of Iron; What Becomes of
Drift Coal, 398. Industrial Items, 405.

The Fourth of July.

If the inherited patriotism of three genera-
tions failed to remind us of the recurrence of
our national birthday, the notes of preparation
which come from every side would impress the
fact that the anniversary of Independence is at
hand. California, though yet in her youth as a
member of this confederation, which had its
christening in the last century, falls behind
none in her devotion to its principles and
reverence for the memory of its creators.

From all sections of the State we note ar-
rangements being made, and by the time this
number of the PRESS is placed in the hands of
our readers, decisive action will have been
taken by many for the proper observance of
the day. We notice by one of our exchanges
that some over proper correspondent is averse
to the waiving of powder and indulgence in the
post festum headach. But we apprehend that
few Americans will be willing to forego the
traditional bell ringing, cannon firing, drum
beating and speech making celebration of Inde-
pendence which has always marked the day as
the brightest in our calendar.

The present year is a particularly memorable
one, marking, as it does, a century since the
first blood was shed in that struggle which an-
other twelvemonth stamped with the impress
of independent nationality, the prelude to one
of the most eventful dramas in the world's
history. '75 was to '76 the needful nursery
which gave our ancestors training for that
irrevocable plunge which was to make or mar
their fortunes.

The ninety-ninth anniversary of the inde-
pendence of the United States! What a deal
of crystallized progress, of condensed history
is contained in these words. To us they are
pregnant with much. What would they be if
they could be heard by those now hushed in
death? We can understand the meaning of the
lines which Dr. Holmes puts in the mouth of
his heroine of Bunker Hill:

"Tis like stirring living embers, when, at eighty, one
remembers
All the aching and the quakings of "the times that
tried men's souls;"
When I talk of *Whig and Tory*, when I tell the *Rebel*
story,
To you the words are ashes, but to me they're burning
coals.

San Salvador Mines.

In our last issue we stated in some remarks
on San Salvador mines that our informant
would give us some further details of the Loma
Larga mine. We have since had a call from
Mr. Flint, who recently arrived from these
mines, and who is quite sanguine that if the
requisite capital to work the mines was forth-
coming some very rich properties could be
developed. The mineral districts of San
Miguel and Santa Rosa extend over an area of
500 miles. The country is hilly and broken,
but most of the mines are accessible by wagon
roads. There are a number of old mines there
which were worked by the Spaniards as deep
as could well be done without machinery.
Lately some impulse has been given to mining
and several of these mines have been opened,
which are now yielding ore of good quality.
No quartz machinery is in use however, and
only a few arrastras are running. Mines in
San Salvador cannot be renounced by fore-
igners; they have to be either purchased or rented.
The ores are easily worked, being principally
chlorides and sulphurates.

The Loma Larga, the principal mine there,
is fourteen leagues from the sea shore, by a
good wagon road. The nearest port is La
Union. The ores have averaged, our informant
states, from \$600 to \$2,500 per ton. The ores
which have been worked there in a rude way
have yielded \$80 per ton in an arrastra. The
mine has been extended on the vein 500 yards.
There is plenty of water and wood sufficient
for all purposes, to which the owner has an ex-
clusive right.

The mine was formerly worked by one
Gorral, who extracted some \$500,000 above
expenses. When he got down deep enough to
require machinery he sold it for \$50,000. This
parties having no capital afterwards sold to
the present owner, General Gonzalez, President
of San Salvador, for \$56,000. Including the
purchase money, he has spent upwards of
\$100,000 on the mine, getting it in order. It
was full of water and after this was removed
new timbers were put in. This long tunnel
which was intended to drain the upper part of
the mine has been put in order, cleaned out
and nearly all re-timbered, and work is still
being done on it. This tunnel only taps the
mine seventy feet from the surface, while the
deepest workings are 300 feet. Another shaft
has tapped the vein 800 yards from the old
shaft. While the mine is being put in order
about half a ton of ore a day is extracted by
being brought up on the backs of Indians, who
climb up notched timbers in a primitive way.

General Gonzalez has a small steam engine
and pump on the mine, and is blasting and
sinking on the new shaft. He wants some
practical mining men to take hold of the mine
with him and purchase a two-thirds interest.
Our informant states that it is a *bona fide* con-
cern, and if some practical man with money
would take hold of the mine and work it
properly, he could make a considerable profit.
The vein in the Loma Larga averages three feet
four inches in width, the ore containing silver
and some gold. There are several other mines
near by with broader veins but lower grade
ores.

Any one who is interested enough to inquire
further concerning these mines can call on
John F. Flint, United States Consul at San
Salvador, Central America, at present residing
at 331 O'Farrell street, in this city. He has
with him maps and plans of the mines show-
ing the workings, etc., and numerous samples
of the ore. To go to the mines will require an
expense of about \$500, and two months' time
to go and return.

Our Mineral Resources at the Centennial.

We are happy to state that the Smithsonian
Institution intends securing as complete a col-
lection as possible to illustrate the mineral
resources of the United States and the chief
mining and metallurgical products at the
International Exhibition, to be held in Phila-
delphia in the Centennial year 1876. This col-
lection will constitute a portion of the govern-
mental display, made by the executive depart-
ments, in accordance with the executive order
of March 5th, 1875, and an act of Congress of
March 3d, 1875. A representation of the great
variety of mineral productions of the country
has not yet been systematically collected and
exhibited by the general government. Such a
collection, formed and arranged with skill and
discrimination, is important for the purpose
of a general view of the extent and variety of
these productions at the exhibition, and will
constitute a portion of the national museum at
the Smithsonian, where it will be permanently
arranged after the exhibition.

At each of the great international exhibitions
abroad, the respective governments caused
liberal and methodical displays of mining in-
dustry and its products to be made co-
ordinately with agriculture and its products.
These displays were not only of great direct
service to the countries making them, but ad-
vanced the knowledge of geology, mineralogy,
mining and metallurgy. In making such col-
lections, the governments of Europe had the
advantage of the aid of organized corps of
mine engineers in the service of the State. In
the absence of such an organization in the

United States, a great part of the labor of ob-
taining a just representation of its mineral
wealth must be left to voluntary patriotic
effort.

Although the Smithsonian Institute is aware
of the great difficulty of obtaining the collec-
tion referred to, especially in the limited time
remaining, it confidently asks and relies on the
heartily and patriotic co-operation of mine
owners, superintendents, engineers, geologists
and all who are able to contribute to the success
of the object in view. The collection now in
the museum will be freely used for the purpose.
The expenses of transportation and exhibition
will be defrayed by the Institution, under suit-
able restrictions, and due credit will be given
in the exhibition and catalogue both to the
locality and contributor. The organization
and general direction of this work have been
conferred to Professor William P. Blake, New
Haven, Conn., to whom all correspondence relat-
ing to it should be addressed. Professor
Blake is so well known in mining and scientific
circles that no assurance is needed that he will
perform the work in a satisfactory and able
manner. We hope that the mine owners of
the Pacific coast will take an interest in this
matter, and an active interest. They ought to
send a collection from here which will open
the eyes of the world to our mineral resources,
of which so little is known on the other side of
the mountains. The iron and coal industries
will of course be well represented at the Cen-
tennial, and our gold and silver should be also.
Our mineral products are so varied and exten-
sive that we should get up an exhibition to do
credit to the coast, and now that the govern-
ment has taken hold of the collection of speci-
mens, etc., those interested should respond
heartily.

Machinery on the Comstock.

To give casual readers an idea of the amount
of pumping and hoisting machinery being put in
on the Comstock, we gather from the last sum-
mary of the local papers a few items relating
to it. At the Dayton mine the erection of the
new and massive pumping and hoisting ma-
chinery is being driven to completion as fast as
is consistent with the thoroughness and dura-
bility of the work. The new and powerful air
compressor on the Sierra mine, now being put
up, when once in operation, will be the most
powerful and complete on the line of the Com-
stock. On the Globe Consolidated a new and
powerful pump is being placed in position,
which it is confidently believed will be amply
sufficient to drain the water from the lower
levels, as soon as it is ready to start. At the
Lady Washington the heavy new pumping and
hoisting machinery is being put into working
position as fast as is expedient and consistent
with perfectly secure and substantial construc-
tion. On the Consolidated Virginia the erec-
tion of the new hoisting and pumping ma-
chinery is making rapid headway, all the men
that can be worked to any advantage being
employed on the works. The Caledonia mine
machinery for the hoisting works at the new
shaft continues to arrive almost daily, and its
erection is being pushed to completion as fast
as the nature of the work will permit. At the
Buckeye mine the boilers for the new machin-
ery are in place, and the erection of the pump-
ing machinery is making rapid headway. On
the Utah mine the erection of the new hoist-
ing machinery is rapidly approaching comple-
tion, all the laborers and mechanics being
employed that can be worked to advantage.
Grading on the Prospect mine for the new
hoisting works is now completed. The new
hoisting works on the Empire mine will soon
be in working position. New pumps are being
put in the Imperial-Empire mines. In the
Overman the new pumps are working splen-
didly, lifting a small river of water, and are
fast gaining on the flow, so there now appears
a fair probability of soon getting it again under
complete mastery. On the Savage the new in-
cline machinery is working splendidly. These
few items, from one issue of a local paper
show that the mechanics of this coast get a
pretty good share of work from this one mining
district alone.

DOUBLE SHEET.—We shall issue twenty-four
pages in the next number of the MINING
and SCIENTIFIC PRESS, which will con-
tain the revised statutes of the United States
relating to mining. It will also contain an ex-
haustive article on lead, with very full tables
for the determination of lead ores, prepared
expressly for the Press by Mr. Henry G.
Hanks. Extra copies of this number will be
printed and sold for the usual price—ten cents.
The revised statutes of the United States are
now printed in our mining law pamphlet, with
all the government laws relating to mining.
Price, 50 cents.

The railroad track is being rapidly laid out
from Spadra. About nine miles of road is
finished. The whole road to San Geronimo
pass will soon be ironed and in running order.
The men are now laying about a mile of track
per day.

THE COAST REVIEW for June contains the
proceedings of the National Board of Under-
writers and other matters important to the in-
surance classes.

THE Cincinnati equatorial telescope, made in
Munich for the observatory, has arrived, and
will be placed in position this week.

San Francisco Enterprise.

The Construction of a Model Mill.

Keeping well abreast with other branches of
mechanics, the wheel-wright has made improve-
ments which entitle him to a first rank among
our progressive artisans. California wheat has
a reputation which is not confined to any section,
but maintains for itself a place in the markets
of the world. By the use of improved milling
facilities, we are able to make a flour worthy of
our wheat. The demand for flouring and grist
mills is rapidly on the increase on the Pacific
coast. To meet this demand, the firm of
Messrs. Joseph Wagner & Co., of this city,
have turned their attention, and they are now
supplying all kinds of milling machinery and
ready to furnish estimates or contract to order
anything from a sixteen-inch portable mill to
the largest class flouring mill, at their estab-
lishment, Nos. 113 and 115 Mission street.

Messrs. Wagner & Co.

Manufacture one of the best machines now in
use for extracting oats, barley and cookie from
wheat. We refer to this improved barley and
grain separator. This ingenious device is the
invention of Mr. M. O'Brien, junior member
of the firm, and has but recently been patented.
The improvement which distinguishes this
separator from all others is simple but most
effective. By means of an overflow screen
attached, the capacity is increased from forty
bushels per hour, the maximum allowed for
ordinary separators, to 150 bushels per hour.
The capacity is regulated by spouts, which can
be fixed to separate any desired number of
bushels per hour.

To give some idea of the facilities possessed
by this house for constructing mills, we might
say that a little less than two months since
Messrs. Wagner & Co. contracted with Mr.
Jacob Samm to put up a mill for him on First
street, corner of Clay, Oakland. It is now
completed and ready for grinding. The build-
ing which contains the mill is forty by sixty
feet, with an addition for an engine room, and
three stories high. An examination of the
premises conveys an excellent idea of the

Model Mill.

It is fitted with the most approved machinery
throughout, has five run of stone and will turn
out 200 barrels of flour in twelve hours. The
mill, which faces on First street and the water
front, is admirably situated to receive grain and
deliver flour either by vessel or rail, as a side
track of the C. P. R. R. runs along First
street.

The wheat after being received is taken from
the bin and subjected to a rougher to remove
the straw; then elevated, run into a suction leg
and after being submitted to three suction
passes into the

O'Brien Separator.

Where all the barley, oats, etc., is removed;
from this separator it goes to the smut ma-
chine, one of the "Eureka" pattern, for which
Messrs. Wagner & Co. are the agents on
this coast, where it is cleaned of smut. It is
then carried to the wetting conveyor and thor-
oughly wetted. This is a phase of milling un-
known to millers of the Eastern States and is
made necessary by the peculiar dryness of the
California wheat, which requires a good degree
of moisture to fit it for grinding. It is now
elevated to the wetting bin where it is allowed
to stand from twelve to twenty-four hours.
This raises the outer and toughens the inside
coat of the berry of the grain. It is then sent
through the amutts a second time to remove
the outside coat, already loosened, leaving the
berry perfectly clean. The grain is then run
into stock hoppers over the mill stones and
ground. As it comes from the stones the flour
is put into the bolt chest where it is separated
from the bran and middlings. The middlings
are then put through a La Croix purifier which
separates all the light bran and fuzz from them,
and the residue, which contains a large amount
of the richest gluten of the wheat, is reground,
and what was formerly only an inferior grade
of flour is made by this improved process into
the best brands. The

"Excelsior" Bran Duster.

Another first class machine of the kind, for
which Messrs. Wagner & Co. are agents, then
takes charge of the bran. What is saved by
this machine is put into superfine flour. After
the flour is ground and graded it is ready for
the "Eureka" packer, a machine which will
pack for delivery 150 barrels per day.

The milling machinery is driven by a fine
engine, manufactured by the Union Iron works,
of one hundred horse-power.

We have been thus particular in noting the
process of manufacturing flour at this mill as
it is done by the most approved machinery
worked on the most approved plan. Con-
structed as the mill has been in so short a time
and yet so admirable in all its arrangements
and perfect in all its details, it reflects a great deal
of credit upon the contractors and upon the
city which affords encouragement to their en-
terprise and skill.

LEAD.—As we will issue a double sheet next
week, we have concluded to defer the publica-
tion of Mr. Hanks' article on lead until
then, so that it can be given entire in one issue.
The table accompanying it are quite exten-
sive and interesting, and the whole article will
be well worth preserving.

Hints on the Washoe Process.

(Continued from last week.)

The Straining of Quicksilver, Cleaning of Amalgam, and Retorting—Continued.

Even at a cherry-red heat, however, the retort gradually gets out of shape, and once out of shape it soon bursts or cracks. To preserve the original shape as long as possible I found it advantageous to hang the retort on four slings. Each of these is a semi-circular cast-iron brace, on which the retort rests. Wrought iron rods, so attached that they can be renewed if burned out, are fastened to the cast iron braces, one on each side of each brace. These rods pass through the brick work, and through flat bars of iron on top, and have, above all, loosely fitting nuts. Of the flat bars on the top of the brick work, four pass across over the retort on the top of the brick work, and two lie likewise, one on each side, and thus the retort is hung on four braces, attached to one common support. If it becomes bulged at all, the string nearest the distorted place may be raised by means of the nuts, and in the next heat the retort will resume its proper shape. In this way, and by a careful and moderate heat, I was able to make retorts last one and a half years in constant use.

The Saving of Slimes and Subsequent Treatment.

By slimes or slime I do not mean to include any slimes whatever from the pan-tailings. If the ore has been properly and exhaustively worked, there is not left in any part of the tailings from the pans any gold or silver that can be recovered by working these tailings, unless they be roasted, or exposed to action of air and moisture for many years. The slimes here spoken of have never come in contact with quicksilver and have never been worked at all; they are carried off mechanically by the waste water that leaves the last tank below the battery, and they assay, as a rule, about sixty per cent. as much as the ore. Generally the assay buttons from the slimes are worth much less per ounce than from the ore, i. e., they contain proportionally less gold. The percentage of slimes varies with the amount of clay, and also depends much on the quantity of water used, and the method of settling. In hard ores, with careful settling, the slimes amount to two or three per cent. of the weight of the ore. The gold in the slimes is very light and flat, the silver occurs largely in refractory sulphurets, and also in a very finely divided state. The slime from ore worth \$16 a ton or upward, may be worked with profit. In one's own mill, working one's own ore, it would be economical to raise to a supply tank above the battery all the water escaping from the tanks, and let it pass again, with the additional water necessary, through the battery. Thus there would be no loss in slimes, as none would leave the mill. But frequently such a change cannot be made in an old mill. In such cases it is necessary to build slime-yards outside the mill. I built my first one in the summer of 1868, after studying a year on the best way to save the slimes; and subsequently I added others, constituting a series, in each of which in succession all the battery water settled before finally escaping. By means of a bull-wheel, rope, car and railroad, the slimes were delivered, when they were to be worked, directly to the pans. The richest of the slimes settled in the first yard, since none of them had ever been in contact with quicksilver or worked in any way, and they were kept entirely separate from the pan-tailings. Working these slimes by themselves, it is difficult to obtain over sixty per cent. of the assay value, even when large amounts of chemicals are used. Moreover the loss of quicksilver is very large. But by mixing ore and slimes in equal proportions more body can be given to the pulp, and in this way I obtained almost as high a percentage as on ordinary ore, and saved much of the quicksilver that would have been lost. The gain was so decided that, not having a mine, I bought ore to mix with the slimes.

(To be Continued.)

THREE of the Black Hills party who recently had property destroyed by the military, have sued the Government officers who destroyed their property, and claim damage to the amount of \$22,000.

THE P. M. S. S. Co. are to inaugurate a new line between this city and New Zealand. The *Granada* will be the first steamer to sail in the line during the coming month.

Short Lectures on Patents.

No. 9.—By JNO. L. BOONE, of Dewey & Co's MINING AND SCIENTIFIC PRESS Patent Agency.

Trademarks.

"S—T—1860—X."

It would be impossible to choose a more appropriate heading for a lecture on trademarks than the one above written. Nearly every person who is familiar with the English alphabet has read it on fences, on houses, on sign-boards, on rocks by the roadside, on the mountain, in the forest, and on the plain, and many a brain has been fruitlessly puzzled in a vain endeavor to discover its meaning. No trademark was ever more effectively advertised. Its very style indicates that there is a significance in its meaning, and this causes it to attract the attention of every person who sees it. The proprietors of this trademark became wealthy and thus the prediction of the trademark that the proprietors had a sure thing in 1860, ten years from the beginning of their enterprise, was verified. Its proprietors inaugurated a system of advertising that has grown to be almost universal.

A trademark may be a word, letter, figure, symbol or character. In order to be patentable it must not be generic of the article it is to represent; neither can it be descriptive, but it must be entirely foreign to both the article and its constituents. For instance, it has been decided that Wine Bitters cannot be held as a trademark because the word wine is descrip-

tion of a patent, or certificate of registration which has all the force and effect of a patent, for the protection of trademarks, and the matter was taken out of the hands of the Clerks of the United States District Courts and placed where it ought to be, under the supervision and control of the Commissioner of Patents.

A certificate of registration or patent is therefore now issued to protect trademarks, and they are subject to examination and rejection for proper causes the same as applications for mechanical patents. Under the old method a person in California could have his trademark registered in the Clerk's Office of the District Court in California and another person could record the same trademark in the Clerk's Office of any other District Court in the United States without question or examination, and the recording would literally amount to nothing. As the law now stands a trademark can be fully and completely protected. Many persons contend that a trademark can be copyrighted and that a copyright is all that is required for its protection. This is entirely a wrong idea. If a trademark is registered according to law it is an infringement of the right of the proprietor for any other person to use that trademark on the class of goods for the protection of which the patentee claims it. If it is only copyrighted and a person should come into possession of a number of printed marks of the same kind, he could not be prevented from using them in any manner he might see fit, and he could place them upon any articles he desired to without infringing the rights of the copyright or in any way laying himself liable. The law has provided a special protection for every class of invented and original productions, and this pro-

A Colorado Lake.

Among the many beautiful views which the photographer accompanying Prof. Hayden's last expedition to Colorado has made it possible for us to admire is one of Upper Twin lake in the Sawatch range of mountains. An engraving on this page gives an idea of the placid loveliness of the lake and its romantic surroundings, as seen by the artist and transferred to paper by the aid of his camera.

The crest of the divide at the head of the south branch of the Little Platte, says Prof. Hayden, presents a fine view of the valley of the Arkansas toward the West, with the grand range of the Sawatch on the west side like a gigantic wall, with its wilderness of peaks, upward of 13,000 and many of them 14,000 feet. Nestled at the base of the Sawatch, at the mouth of the Lake Creek gorge, are the beautiful Twin lakes, separated from each other by a belt of moraine deposit only about 200 yards wide, with a small stream flowing from one to the other, 20 feet wide. The upper lake is one mile in length and half a mile in width. The greatest depth found by sounding was 76 feet.

To the southeast may be seen distinctly the ranges about the San Luis valley, with Uncompahgre peaks rising far above all the rest. To the east we have the South Park full in the foreground, looking like an immense meadow. The ridges which run across it in different directions are softened down by the distance. Pike's peak, with the ranges of mountains on either side, shuts off the vision from the broad plains beyond; it rises so far above the rest that it becomes a most important landmark for a radius of fifty or eighty miles in every direction.

To the northeast and west is the splendid group of peaks of which Mount Lincoln is the crowning one; while to the northwest are the sources of the Arkansas with the Tennessee pass and its associated ranges of mountains. The Blue River range can be seen dimly beyond. Such are the geographical features of this remarkable region, and I describe them from time to time, to convey to the reader the fact that the variations are kaleidoscopic, and from every important mountain peak a fresh and equally grand view may be obtained.

DAMAGING RAINS—SUSPENSION OF HARVESTING.—The last week has been a bad one for the farmers. The storms of the 15th and 16th have caused serious damage throughout the State. The accounts that come from various quarters are of remarkable uniformity. Hay has suffered most; large quantities were baled and stacked upon the ground, much of which will be spoiled. The uncut grain is beaten down and damaged to some extent and that in stacks is in a still worse condition. Dry feed and summer fallowed grain are also injured. Harvesting is generally suspended until the weather clears up; and when it is resumed it will be more irksome and wasteful on account of the lodged grain. Some crops, however, have been greatly benefited by the storms. Hops, tobacco, potatoes and corn will, no doubt, give a larger yield on account of these rains. Fruit is reported to be beaten from the trees to some extent, but the damage in this quarter will probably be slight. Much anxiety is felt concerning the extent of the damages from this unusual storm.

Progress at the Suto Tunnel.

The following is the report of progress in the Suto tunnel, for week ending June 8, 1875:

Number of feet in tunnel, June 1..... 9,680

Number of feet driven during week..... 70

Distance in June 8..... 9,650

Details of work performed are as follows, heading being 8x10 feet:

Holes drilled..... 443

Holes blasted..... 133

Aggregate depth..... 2,528 feet

Average depth..... 16 7/10 feet

Powder consumed..... 1,247 lbs

Explosives consumed..... 690

Car Loads..... 438

ROCK.—Tough conglomerate, greenstone base with angular pieces of trachyte.

[Signed] A. SUTRO, Gen. Supt.

Two miles of track have been laid on the Vaca valley railroad. The work is now suspended for lack of ties.

UPPER TWIN LAKE, COLORADO.

tive of the article bitters and forms a part of a real name which any one can use that makes a bitter out of wine, but Excelsior Wine Bitters or I X L Wine Bitters are subjects of legal trademark because the words Excelsior and I X L are neither descriptive or generic, but are entirely foreign to the article bitters. A personal name is not the legal subject of a trademark. Smith's Rye Whisky could not be patented as a trademark. The rule is that in order to render a trademark patentable it must contain a word which is coined for the intended case. The Patent Office refused to register the phrase "American Sardine," which the applicants intended to place on cases resembling sardine boxes but which contained another kind of fish, because the mark was intended to deceive the public. The name under which a patented article was sold during the existence of the patent was refused registration because it had acquired a distinctive meaning and had lost its character as an arbitrary symbol. "When a device becomes public property its name must also," and this is the case even if the name was coined for the purpose when it was adopted, and might have originally been the proper subject of a patent. The law is thus strict in order to protect the public from deception and imposition. Previous to 1870 there was no special legal provision regulating the manner of securing to proprietors the right to a trademark, and the only formality employed was to file a copy of the proposed trademark in the office of the Clerk of the United States District Court, pay a fee of two dollars and a half and receive a receipt therefor. Occasionally a person who placed a higher estimate than usual on a trademark would apply for and obtain a mechanical patent covering it, in which case the patent was issued "for a trademark" and the fees required were the same as were required in mechanical cases. But the law of 1870, which went into effect in July of that year, made special provisions for the issuance

tion is as thorough and complete in one class as it is in another. A design patent or a trademark patent is as effective to ward off infringements of the thing patented as a mechanical patent is to protect the inventor in the possession of his invention, while their cost is less. The quality of invention required to produce a new design or trademark is inferior to that required to produce a new and useful piece of mechanism or to unravel a mechanical problem, yet it is often the case that the two former are the most profitable to the patentee. A trademark soon identifies itself not only with the article upon which it is placed but also with the proprietor. If we speak of Mr. Brown who manufactures bitters called "The I X L Bitters," we are apt to call him the I X L Bitter man, especially if we are at a loss to call his proper name at once, and when this is the case we can safely calculate that Brown's bitters are pretty thoroughly advertised, for every such remark is an advertisement for him. The best trademarks are those which most readily attract the attention of the public, and much ingenuity is displayed in getting up some of our present day trademarks, especially some of the burlesque designs and comic mottoes. It matters not, however, what a trademark is, whether it be a word, figure, character or design, its persistent use upon the article it is to represent will finally connect the one with the other in the minds of consumers, and the mark will become valuable as a part of the stock in trade of the manufacturer or proprietor.

A trademark remains in force for thirty years from the date of registration, and at the expiration of that time it can be re-registered for a further term of thirty years, but when the trademark is also secured in a foreign country its protection in this country will cease simultaneously with the foreign protection, without reference to the original term of the grant.

Miscellaneous Notices.

Tenth Industrial Exhibition of the Mechanics' Institute, S. F., 1875.

PRELIMINARY ANNOUNCEMENT.

The Board of Managers of the Tenth Industrial Exhibition has the pleasure of announcing that an Industrial Exhibition will be held, under the auspices of the Mechanics' Institute, in the city of San Francisco, to be opened on Tuesday, the 17th of August, 1875, at 11 A. M., and to continue open at least one month thereafter.

In making this public announcement, the Managers desire that those who intend to exhibit should send in their applications for space as early as possible, so as to avoid the necessity of excluding, as has been the case heretofore, the many desirable exhibitors who are unusually tardy in making applications.

The forthcoming Industrial Exhibition will be the tenth held under the auspices of the Mechanics' Institute, and the Managers are justified in saying that it will undoubtedly surpass in completeness of detail and general arrangement any heretofore held.

The last Exhibition was attended by 700,000 visitors, attracted hither by the fame of these Industrial Fairs, and for the purpose of investigation, business and pleasure.

All the available exhibiting space was applied for several weeks before the day of opening, and the Managers were compelled to deny admission to many desirable exhibitors.

The Board of Managers desire particularly that the arts, the industries and natural products of the country should be well represented at the forthcoming exhibition, and no pains will be spared to make these classes of exhibits a special feature there.

The Exhibition will be held in the building constructed for that purpose in 1874, but it will be materially enlarged and improved in many details for the Exhibition of 1875.

The space under roof will exceed 180,000 square feet, or about four and a half acres, exclusive of the Horticultural Garden, which will occupy 24,500 square feet additional.

The location of the Exhibition Building, on Eighth street, between Market and Mission streets, cannot be surpassed for convenience and accessibility, and can be approached from every part of the city by means of the various lines of street railroads, any of which bring visitors within two blocks of the entrance gate.

The utmost care has been exercised in providing for ample ventilation and light, and during the evening the building is brilliantly illuminated by over 5,000 gas lights.

The promenade avenues are broad, and 3,000 seats are provided for the comfort of visitors, for whose convenience there is also an excellent restaurant, under the management of a first-class restaurateur.

Every afternoon and evening the best orchestra the city can supply will discourse excellent music under the direction of an accomplished leader.

The building is always well attended by visitors, and during the last Exhibition over 29,000 were daily admitted for a number of days, and under no similar circumstances at the same exhibition, the mechanic, the inventor, producer or business man so advantageously place himself before the people of the Pacific Coast.

Persons desiring to obtain information, or to make application for space, should address "Managers of Tenth Industrial Exhibition, San Francisco, California," or make personal application as below.

It is expected that the various transportation companies will convey goods intended in good faith for exhibition, at half the usual rates.

Exhibitors from abroad, if they have no agent or consignee in San Francisco, can consign goods and mark the same to the "Manager of the Tenth Industrial Exhibition, 17 Post street, San Francisco," and they will be stored, if they arrive before the day of opening, free of expense, but no charges or expenses for freight or forwarding, etc., will be paid by the Managers.

In order to secure space, application should be made on or before July 20th, 1875.

Blanks will be furnished on application.

Premiums will be awarded as follows, viz: 16 gold medals, 50 silver medals, Society Diplomas, Certificates of Merit and Special Premiums, as the Board may determine.

Blanks for space can be obtained at the Mechanics' Institute on application by letter or otherwise; and any information will be given, by applying to any member of the Board of Managers, as below:

A. S. HALLIDAY.....113 Pine street.
JAMES O. PATRICK.....122 Battery street.

JAMES SPIERS.....311 Howard street.

To the Librarian of the Mechanics' Institute, or to J. H. CULVER, Secretary, 27 Post street, San Francisco.

Rules and Regulations of the Tenth Industrial Exhibition, Mechanics' Institute, S. F., 1875.

1. The Pavilion will be open for the reception of goods on Monday, August 2d. The exhibition will be open to the public on Tuesday, August 17th, at 11 o'clock A. M.
2. Applications for space must be made on or before July 20th, stating character of exhibit, amount and kind of space required—wall, table or floor. And, if cases, state length, width and height of case. Blanks will be furnished for this purpose, and a clerk will be in attendance at the Library of the Mechanics' Institute, every day from 12 to 1, and 7 to 10 P. M.
3. All persons presenting articles for exhibition must have them registered by the receiving clerk, who will give a receipt for the same, which receipt must be presented when the articles are withdrawn, at the close of the Exhibition.
4. Judges will be appointed by the Board of Managers, immediately upon the opening of the Exhibition, to examine all articles presented, in accordance with Article III, and the Managers will award premiums on such articles as the judges shall declare are worthy, which will be delivered as soon as they can be prepared. Due notice will be given of the announcement of premiums.
5. The mornings of each day, until 10 o'clock, will be appropriated to the Judges, and no visitors will be admitted during the time thus appropriated, except at the special request of the Judges, or by permission of the Managers.
6. Articles intended for sale may be labeled accordingly, but cannot be removed until the close of the Exhibition, except by written permission of the Managers.
7. Steam power will be provided, so that machinery

of all kinds may be seen in actual operation, and every facility possible will be given to exhibit working machinery to the best advantage.

8. The name of every article must be attached by the exhibitor to it.
 9. Articles intended for exhibition must be entered and placed on exhibition on or before Saturday, August 21st.
 10. Portable articles will be received, or may be removed at any time during the exhibition, with the consent of the Managers.
 11. The most effectual means will be taken, through the agency of the Police and otherwise, to guard and protect the property on exhibition; and it will be the purpose of the managers that all articles shall be returned to the owners without loss or injury. Still, all articles deposited will be at the risk of the owners.
 12. In case of any misunderstanding, application may be made to the Managers, who will at all times be in attendance.
 13. The Managers are desirous that articles should be presented early. Those from abroad, intended for exhibition, should be properly packed, and if not consigned to exhibitor's agent, must be marked, "MANAGERS OF TENTH INDUSTRIAL EXHIBITION, SAN FRANCISCO, CAL." All articles thus received, arriving too early, will be stored free of cost to the exhibitor, and the Managers will have them duly placed in proper position for exhibition. No freight charges will be paid by the Managers; but exhibitors are notified that arrangements are being made with various transportation companies to repay freight charges on evidence of goods prohibited.
- Information will be furnished by addressing MANAGERS OF TENTH INDUSTRIAL EXHIBITION, SAN FRANCISCO, CAL.

LEVI, STRAUSS & CO., Patent Riveted Clothing,

Ayer's Cherry Pectoral,

For Diseases of the Throat and Lungs, such

as Coughs, Colds, Whooping Cough, Bron-

chitis, Asthma and Consumption.

The few compositions, which have won the confidence of mankind and become household words, among not only one, but many nations, must have extraordinary virtues. Perhaps no one ever secured so wide a reputation, or maintained it so long, as AYER'S CHERRY PECTORAL. It has been known to the public about forty years, by a long continued series of marvellous cures, that have won for it a confidence in its virtues, never equalled by any other medicine. It still makes the most effectual cures of Coughs, Colds, Consumption, that can be made by medical skill. Indeed the CHERRY PECTORAL has really reached these dangerous diseases of their terrors, to a great extent, and given a feeling of immunity from their fatal effects, that is well founded, if the remedy be taken in season. Every family should have it in their closet for the remedy and prompt relief of its members. Sickness, suffering and even life is saved by the timely protection. The prudent should not neglect it, and the wise will not. Keep it by you for the protection it affords by its timely use in sudden attacks.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Suppl. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburgh Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammers—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting laps, increased value of amalgam by absence of iron dust and chipping, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to
CAST STEEL SHOE & DIE CO., Room 1, Academy Building, S. F.

JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setters made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 239 Fremont Street, San Francisco

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., June 15th, 1875.

FOR WEEK ENDING JUNE 1st, 1875.

MACHINE FOR BENDING HORSE SHOES.—Arthur Barton, Nevada, Cal.

AMALGAMATOR.—Wm. H. Carson, San Jose, Cal.

ATTACHMENT FOR COOKING STOVES.—Frank Enos, Mineral City, Nevada.

ENDLESS ROPE TRACTION RAILWAY.—A. S. Hallidie, S. F., Cal.

FUME BATTERY.—D. F. Hawkes, Timbuctoo, Cal.

CUTTER HOLDER FOR METAL LATHES.—J. R. Mitchell, Hayward, Cal.

SLOW MATCH FOR LIGHTING FUSES.—Adam S. Wall, Graniteville, Cal.

PROCESS FOR PREPARING COCOANUT FOR DOMESTIC USE.—Alex. P. Ashbourne, Oakland, Cal.

TRADE-MARK.

FOR MATCHES.—John W. Tucker, S. F., Cal.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. Note.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect accuracy and in the shortest possible time.

General News Items.

Last Sunday morning, as one of Montgomery Queen's circus wagons, from which the horses had been unhitched, was being moved down Carson street, Virginia, by three of the attendants, those in charge lost control and the ponderous vehicle dashed down the steep incline at a terrific rate of speed and finally plunged into a dwelling house on I street. In the front room a young lady named Gilmore was in bed with her little niece. The wagon broke through the front of the house, completely demolishing it, and severely injuring Miss Gilmore.

JACK COTTON and Mrs. Norton, the chief and accomplice in the Santa Barbara Co. tragedy, passed through this city on Monday for Santa Barbara. They were arrested at Wadsworth, Nev., where Jack had found employment after fleeing from the scene of his crime.

A CHILD in Auburn, Placer Co., was attempting to pick the inside out of a giant powder cap with a pin, some days ago, when the cap exploded, blowing off part of the thumb and forefinger on his right hand.

HORACE B. CLAFLIN, John Claflin, Daniel Robinson, Dexter N. Force and W. H. Talcot, merchants of New York, have given bail in \$20,000, under indictments against them for silk smuggling.

ATELL has been transferred from Utah to New Mexico as Governor, and the President has appointed as his successor among the Mormons George W. Emory, of Massachusetts.

CONGRESSMAN-ELECT Wm. S. King, indicted in connection with the Pacific Mail subsidy, was admitted to bail on Saturday last in Washington, in the sum of \$5,000.

IDA DAMEBONS, aged 14 years, who was fishing in a skiff tied to the ferry boat at Knight's Landing, last Friday afternoon, fell overboard and was drowned.

JOHN P. GARNER, a prominent merchant of Boston, suicided last week. No cause attributed. Wealth abundant—family relations agreeable.

THE State Teachers' Convention was held in San Jose last week.

A REVIVAL is in progress in Stockton.

Agricultural Items.

THE Novato ranch, in Novato valley, half way between Petaluma and San Rafael, and about twenty-five miles from San Francisco, is offered for sale. It contains about 15,000 acres of land.

THE Olympia, W. T., Farmer says: Cherries will soon be ripe; wild strawberries are ripe and seem to be plenty this year, but it is said that plums will be rather scarce.

A BUNCH of oat stocks six and one half feet long, grown this year on a ranch near Watsonville, was shown to the editor of the Pajaronian the other day.

PREPARATIONS are being made for putting the swamp lands to the south of Bakersfield, along the Kern Island canal, in a high state of cultivation.

JAMES FULTON sold last week to Jacob Keithly sixty-nine acres of land, half a mile from the depot, at Fulton, for \$10,000 in gold coin.

THE work of planting orange orchards was never more vigorously prosecuted in Los Angeles county than at the present time.

THE grasshoppers are doing considerable damage to crops at Eagleville, Modoc county.

Industrial Items.

MR. DAVIS, of Salinas City, is burning a fine brick kiln in the southern part of the town, near his residence. The kiln is 50 feet long, 40 wide, and 14 high, and contains about 350,000 brick.

THE Directors of the Woodland, Clear Lake and Humboldt railroad are at work securing the right of way for the section between Woodland and Capay.

THE town council of San Buenaventura has granted a gas franchise to leading citizens. It provides that works shall be erected within 18 months.

THERE is talk of establishing a wine cellar at Fulton. One-half the stock of \$10,000 is already taken.

THE Union understands that there is something more than talk in the matter of establishing woolen mills at San Diego.

THE Anaheim hotel is to cost \$40,000, will be three stories high and contain eighty rooms.

THANKS "FROM THE DEPTHS OF THE HEART."

WELLINGTON, LORAIN CO., O., Aug. 21, 1874.

Dr. R. V. PIERCE, Buffalo, N. Y.: Dear Sir—Your medicines, Golden Medical Discovery, Dr. Sage's Catarrh Remedy, have proved of the greatest service to me. Six months ago no one thought that I could possibly live long. I had a complication of diseases,—scrofula, manifesting itself in eruptions and great blotches on my head that made such sores that I could not have my hair combed without causing me much suffering; also causing swollen glands, tonsils enlarged, enlarged or "thick neck," and large and numerous boils. I also suffered from a terrible Chronic Catarrh, and in fact I was so diseased that life was a burden to me. I had tried many doctors with no benefit. I finally procured one-half dozen bottles of your Golden Medical Discovery and one dozen Sage's Catarrh Remedy, and commenced their use. At first I was badly discouraged, but after taking four bottles of the Discovery I began to improve, and when I had taken the remaining I was well. In addition to the use of Discovery I applied a solution of Iodine to the Goiter or thick neck, as you advise in pamphlet wrapping, and it entirely disappeared. Your Discovery is certainly the most wonderful blood medicine ever invented. I thank God and you, from the depths of my heart, for the great good it has done me. Very gratefully,

Mrs. L. CHAFFEE.

Most medicines which are advertised as blood purifiers and liver medicines, contain either mercury in some form, or potassium and iodine variously combined. All of these agents have strong tendency to break down the blood corpuscles, and debilitate and otherwise permanently injure the human system, and should therefore be discarded. Dr. Pierce's Golden Medical Discovery, on the other hand, being composed of the fluid extracts of native plants, barks and roots, will in no case produce injury, its efforts being strengthening and curative only. Sarsaparilla, which used to enjoy quite a reputation as a blood purifier, is a remedy of thirty years ago, and may well give place as it is doing, to the more positive and valuable vegetable alternatives which later medical investigation and discovery has brought to light. In Scrofula or King's Evil, White Swellings, Ulcers, Erysipelas, Swelled Neck, Goitre, Scrofulous Inflammations, Indolent Inflammations, Marcurial affections, Old Sores, Eruptions of the Skin and Sore Eyes as in all other blood diseases, Dr. Pierce's Golden Medical Discovery has shown its great remedial powers, curing the most obstinate and intractable cases. Sold by all dealers in medicines.—Com.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

- J. L. THARP—San Francisco.
- B. W. CROWELL—California.
- A. C. CHAMBERLAIN—Tulare, Fresno and Inyo Counties.
- JOHN ROBERTSON—California.
- A. C. KNOX—California.
- G. W. MCGHEE—Santa Clara county.
- CHAS. T. BELL—California, Oregon and W. T.
- D. J. JAMES—Abstralian Colonies.

A COMPLIMENT.

PLAINSBORO, MICHIGAN CO. CAL., June 22, 1874. DEWEY & CO.—Gentlemen: I herewith tender my grateful acknowledgments for the energy, promptness and efficiency which you have displayed in procuring my patent.

Although you were entire strangers to me when I first communicated with you, I soon felt satisfied you were gentlemen of integrity, and shall always be happy to represent you as such. Very truly yours,

H. W. RUCKER, M. D.

CAMPO, SAN DIEGO CO., CAL., July 3d, 1874. Messrs. DEWEY & CO.—Gentlemen: To-day I received the patent and other papers of my animal trap, that you so successfully worked through the patent office for me, for which please accept my best wishes. The chances are that I will have another application for you to make for me before long. I am well satisfied with your manner of doing business, and I think inventors of this coast stand in their own light when they do not put their business into your hands.

I remain yours truly, A. M. GASS.

SANTA CLARA, CAL., April 6th, 1875.

Messrs. DEWEY & CO.—Gentlemen: We have just received Patent No. 160,535, for J. T. Watkins & Co's Mammoth Road Grader, which was patented through your Agency. It is the bestest and best that we have ever received. We feel proud of it and thankful to you for the care and attention that you have given it, and when we have anything to do in that line of business we will surely give you a call. Very respectfully,

J. T. WATKINS & Co.

The Mining & Scientific Press.

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi. As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States. Miners, Assayers, Millmen, and Metallurgists in the United States should take it. Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columns of fresh and valuable information. Mining Engineers, Superintendents, Metallurgists, Mine Owners and Mine Workers throughout the world should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events. Intelligent thinkers throughout the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

DEWEY & CO., No. 224 Sansome street, S. F.

UNITED STATES

Mineral Land Laws, Revised Statutes, and Instructions and Forms Under the Same.

We have just issued a pamphlet containing the general mineral land laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870; Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Register's Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvement; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of MINING AND SCIENTIFIC PRESS, S. F.

N. B.—We have also added to the above publication, the REVISED STATUTES OF THE UNITED STATES, so far as relates to Mining Laws.

SECOND EDITION—REVISED AND ENLARGED.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy.

Containing 672 Pages and 83 Engravings

BY J. S. PHILLIPS, M. E.,

Of California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE, bound in cloth, \$10.50; in leather, \$12. Forwarded by mail for \$60. extra, at the MINING AND SCIENTIFIC PRESS Office, by

DEWEY & CO.

The Large Circulation of the MINING AND SCIENTIFIC PRESS extends throughout

the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana, British Columbia and to other parts of North and South America. Established in 1860, it has long been the leading Mining Journal of the Continent. Its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

Mining and Other Companies.

Geneva Consolidated Silver Mining Company.

Location of principal place of business, City and County of San Francisco, State of California. Location of works, Cherry Creek Mining District, White Pine County, State of Nevada.

Nevada Land and Mining Company—

Location of principal place of business, San Francisco, California. Location of works, Spruce Mountain Mining District, Elko County, State of Nevada. Notice is hereby given, that at a meeting of the Board of Directors, held on the 14th day of May, 1875, an assessment (No. 17) of Two cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the Company, Rooms 5 and 6, No. 302 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 19th day of June, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the 28th day of June, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, WM. H. WATSON, Secretary.

Orleans Mining Company—Location of

Principal place of business, San Francisco, California. Location of works, Grass Valley Mining District, Grass Valley, Nevada County, California. Notice is hereby given, that at a meeting of the Board of Trustees of said company, held on the 31st day of May, 1875, an assessment, No. 5, of two dollars per share was levied upon the capital stock of said company, payable immediately in gold coin of the United States of America to the Secretary, at the office of the company, room 8, No. 315 California street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on the 8th day of June, 1875, shall be delinquent, and day as delinquent, and unless payment shall be made before, will be sold on the 28th day of June, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

Office—Room 8, No. 315 California street, San Francisco, California.

Umpire Tunnel and Mining Company—

Principal place of business, San Francisco, California. Location of works, Big Cottonwood District, Salt Lake County, Utah.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 20th day of May, 1875, an assessment (No. 4) of Five (5) cents per share was levied upon the capital stock of the corporation, payable immediately in United States currency, to the Secretary, at the office of the company, No. 531 California street, San Francisco, Cal., to the Superintendent.

Any stock upon which said assessment shall remain unpaid on the 1st day of July, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 2nd day of August, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

Office, Room 1, No. 531 California street, San Francisco, California.

Virginia Consolidated Mining Company—

Location of principal place of business, San Francisco, State of California. Notice.—There are delinquent upon the following described stock, on account of assessment levied on the 21st day of April, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.

QUICKSILVER.

UNITED STATES PATENT OFFICE.

The Quicksilver Mining Company of New Almaden, California.—Trade-mark for Quicksilver Flasks.
Statement of trade-mark No. 1499, registered October 19, 1873; application filed September 29, 1873.

Specification describing a trade-mark, used by the Quicksilver Mining Company, a company chartered by the State of New York, and working and operating quicksilver mines at New Almaden, Santa Clara county, State of California, for Quicksilver Flasks.
Our trade-mark consists of the letter "A" straddling a circle. This letter has generally been painted upon the upper end of each flask, bottle, or jar in which the quicksilver is contained, its usual position being such that the opening or mouth in the upper end of the flask, bottle or jar will be between the spreading angular sides of the letter, the cross-mark of the letter passing along close to the edge of the hole.

This trade-mark we have used in our business for ten years last past. The particular goods upon which we have used it are quicksilver flasks, and it has always been applied as above described.

THE QUICKSILVER MINING COMPANY.
By J. B. RANDOL, Manager.
This trade-mark is also registered in the office of the Secretary of State, Sacramento, California, and all producers and dealers in quicksilver are cautioned not to use the said trade-mark.
For New Almaden Quicksilver, apply to
THOMAS BELL, Sole Agent,
Over Bank of California, San Francisco.

NEW ALMADEN QUICKSILVER.

TRADE MARK,

The well known full weight and superior quality of the quicksilver produced at the New Almaden Mines having induced certain unscrupulous persons to offer their inferior productions in flasks having our trade-mark, "A," notice is given to consumers and shippers that quicksilver, "A" brand, guaranteed weight, can be purchased only from THOMAS BELL, San Francisco, or his duly appointed sub-agents.
J. B. RANDOL, Manager.
New Almaden, April 5, 1875.

**UNION IRON WORKS,
PRESCOTT, SCOTT & CO.,**
SUCCESSORS TO
H. J. BOOTH & CO.

The copartnership heretofore existing under the name and style of H. J. BOOTH & CO., expired on the 8th day of June, 1875, by the withdrawal of H. J. Booth. The business will be carried on by the undersigned, their successors, at the same place, under the name and style of PRESCOTT, SCOTT & CO., who assume all liabilities of the late firm and to whom all outstanding accounts will be paid.

Having sold out my interest in the firm of H. J. Booth & Co., I ask for my successors a continuance of the liberal patronage so long extended to the old firm. Messrs. Prescott, Scott & Co. will pay all debts of the late firm and collect all outstanding accounts.

**BAIRD'S
BOOKS
FOR PRACTICAL MEN.**

Our new and enlarged Catalogue of PRACTICAL AND SCIENTIFIC BOOKS—96 pages, 8vo.—sent free to any one who will furnish his address.

HENRY CAREY BAIRD & CO.,
Industrial Publishers and Booksellers,
406 Walnut street, Philadelphia.

**Knight's American Mechanical
Dictionary,**

A Cyclopedia of Science, Art and Manufactures, one of the finest as well as most useful books ever published. Nothing else will take its place. It is the only work in existence which gives an adequate view of the present advanced state of mechanical science. Full information regarding over 40,000 separate subjects, with above 5,000 illustrations, costing One Hundred Thousand Dollars (\$100,000). It will be issued in 38 parts, or three bound volumes. The price of each part is 50 cents, payable on delivery. Prices for each bound volume: Cloth, \$7; sheep, \$8; half morocco, \$9.

A GENTLEMAN OF GOOD ADDRESS AND BUSINESS ABILITY, DESIRING PROFITABLE EMPLOYMENT, CAN OBTAIN A GOOD AGENCY FOR THIS WORK BY APPLYING TO

J. B. FORD & CO.,
No. 339 Kearny Street, S. F.

Thursday Noon our last forms go to press. Communications should be received a week in advance and advertisements as early in the week as possible.

**N. W. SPAULDING,
Saw Smithing and Repairing
ESTABLISHMENT.**

Nos. 17 and 19 Fremont Street, near Market.

MANUFACTURER OF

SPAULDING'S

Patent Tooth Circular Saws.

They have proved to be the most durable and economical Saws in the World.

Each Saw is Warranted in every respect: Particular attention paid to construction of Portable & Stationary Saw Mills.

MILLS FURNISHED AT SHORT NOTICE
At the lowest Market Prices.

IRON AND STEEL.

VAN WINKLE & DAVENPORT,

Importers and Dealers in Iron and Steel, Norway and Sligo Iron, Heavy Hardware and Boiler Plate, Axles, Springs, Blacksmith's Tools, etc. Agents for Perkins' Horseshoe and Globe Horse Nails, Sheet-iron, Rivets and Cumberland Coal. All sold at the lowest rates. Nos. 413 and 415 Market street.

THE NEVADA

QUARTZ MINING PROPERTY FOR SALE.
With a new 15-stamp mill, now running. Has its own water power, with houses, shops, etc. Government title; joins the Providence mine, on Deer Creek, Nevada City, Cal. For sale or to bond.

Address,
I. S. VAN WINKLE,
413 Market street, San Francisco.

Ames' Genuine Chester Emery

Has been reduced from seven cents to six cents per pound for grains in kegs, flour and fine flour remaining at four cents per pound, as heretofore. Important discounts to the trade. Send for circular.

E. V. HAUGHWOUT & CO.,
26 Beekman Street, New York.

\$5 to \$20 Per Day at home. Terms free. Address G. STINSON & Co., Portland, Me.

**W. T. GARRATT.
CITY
Brass and Bell Founder,**
Corner Natoma and Fremont Streets,
MANUFACTURERS OF
Brass, Zinc and Anti-Friction or Babbst Msta
CASTINGS,
Church and Steamboat Bells,
TAVERN AND LAND BELLS, GONGS,
FIRE ENGINES, FORCE AND LIFT PUMPS.

Steam, Lignor, Soda, Oil, Water and Flange Cocks, and Valve of all descriptions, made and repaired. Hose and all other Joints, Spelter, Solder and Copper Rivets, etc. Gauge Cocks, Cylinder Cocks, Oil Globes, Steam Whistles, HYDRAULIC PIPES AND NOZZLES for mining purposes. Iron Steam Pipe furnished with Fittings, etc. Coupling Joints of all sizes. Particular attention paid to Dietillery Work. Manufacturer of "Garratt's Patent Improved Journal Metal." Highest Market Price paid for OLD BELLS, COPPER and BRASS.

1874. A GRAND SILVER MEDAL. 1874

PARKE & LACY, Sole Agents,
310 California Street,
SAN FRANCISCO.

The highest and only prize of its class given to any Vertical Engine was awarded to the

HASKINS ENGINES AND BOILERS,

BY THE
MASS. CHARITABLE MECHANICS' ASSOCIATION,
at their Fair in Boston, in competition with the
Baxter, New York Safety Steam Power
and the Sharpley Engines.

**RUSSELL'S
OREON PILE CURE.**

To those suffering from Piles—External, Internal and Itching Piles: You can be cured, as hundreds of others have been. Send for Circular and see undoubted testimony. Will send sample bottle for \$2, or three bottles for \$5.

Call upon your Druggist, or address
DR. RUSSELL,
No. 5 Post street, San Francisco.

San Francisco Cordage Company.
Established 1856.

We have just added a large amount of new machinery to the latest and most improved kind, and are again prepared to fill orders for Rope of any special length and size. Constantly on hand a large stock of Manila Rope, all sizes; Tanned Manila Rope; Hay Rope; Whale Line, etc., etc.

TUBBS & CO.,
611 and 613 Front street, San Francisco

A VALUABLE PATENT RIGHT

For the Pacific Coast,
WITH THE FACTORY FOR SALE.

For further particulars call at, or address,
611 POST STREET, - - SAN FRANCISCO.

TO MINING COMPANIES.

A mining superintendent and engineer, of long experience, wishes to correspond with a view to engage as mining superintendent. Best references given.

Address,
"J. B."
P. O. Box 633, Oakland, Cal.

\$10 to \$500 invested in Wall Street often leads to fortune. A 72-page book explaining everything, and copy of the Wall Street Review sent free.

JOHN HICKLING & CO.,
Bankers and Brokers, 72 Broadway, New York.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEVEY & CO.,
Patent Solicitors.

SAN FRANCISCO, SATURDAY, JUNE 26, 1875.

VOLUME XXX
Number 26.

California Geology.

The Great Plunges on the Tertiary.

At the last meeting of the California Academy of Sciences, Mr. Amos Bowman, formerly of the State Geological Survey, read a paper on the above subject, as follows:

I wish to call attention to the facts, which may be observed and confirmed by residents of nearly every portion of the State, going to show that California has risen out of the sea at the dawn of our creation, that is to say, the creation of the mammals of the tertiary period, and that since this comparatively recent event it sank out of sight again, under the sea, bodily.

Only the mountain tops of the coast counties rose above the surface. The movement was gradual, and affected at least ten degrees of latitude along the shores of the Pacific slope.

This conclusion is so well borne out by the record that, however novel or unsupported it may appear when stated for the first time, I advance it fearlessly, though at present without attempting to follow it up by an elaborate array of proof. It is one of those great truths which, when once announced, can be studied and verified by everybody, and which will stay true for all time.

It first interpreted itself to me during my coal reconnaissance last autumn, when, standing upon one of the highest summits of the coal measures at Napa, in the Monte Diablo coal region, I got a bird's-eye view of the peaks of the overlying tertiary between the coal mines and Suisun Bay, there opened up like a book.

A horizon of marshes, bogs and forests is seen swallowed up by the sea, buried under and covered up by half a mile's thickness of sea sediment, in the upper strata, densely impregnated with the remains of marine life. Like a flash the similarity in position and of subsidence under the sea of a dozen different coal regions widely apart, which I had visited, bearing the same relation to the underlying cretaceous and the overlying tertiary rocks, then for the first time occurred to me.

The last, and most interesting addition to this page of our geological history came to my notice more recently.

A few weeks ago I presented to the Academy of Sciences some stone relics of the earliest known inhabitants of the globe. This conclusion, as a matter of fact, is not stated on my own authority unsupported, but on that of paleontologists, which I will not dispute, because I see no reason for disputing them at this time. It rests in the fact that the formation is identified as upper tertiary or pliocene. The authority is Lesquereux principally, who determined the palms and other extinct forest leaves of our ancient rivers, and Whitney, in volume one of the Geological Survey.

The locality from which these stone mortars, pestles, stone knives, ornaments, etc., were derived, as was stated when they were presented, is the Oroville and Cherokee mesa of Butte county. I remarked, in presenting the stone knife, that, of my own knowledge, the formation was pre-glacial.

Coal deposits and coarse gravel underlying the Oroville mesa, succeeded by finer material, the upper portion of which is an auriferous gold bench, preceding in age the volcanic and the glacial periods of California, testify to the same convergence in the early tertiary, and to the same grand plunge into the sea during the middle and the latter part of the tertiary, the proof of which I saw in so many places in connection with the coal regions explored last autumn.

The contemporaneousness of the submersion in Butte county, and elsewhere in the interior, with that at Monte Diablo, and throughout the coast counties, is based not merely on the fact that there are coal beds of wide distribution marking the former emergence, found alike in both places, but that the underlying rock is cretaceous, so determined by marine fossils, and that the formation at both places comprises the tertiary which were deposited before the advent of the volcanic period. The latter constitutes a sort of geological landmark in California, of the end of the tertiary and of the lowest subsidence of the land, since which time we have had the ice period, and a new emergence of 2,000 feet, which is still in progress.

The stone relics of human origin here presented—to which I add to-night another, of a curious trough-shaped utensil of granite, given me by E. J. Davis, of Cherokee—show that the country was inhabited during the latter part of this subsidence, these relics having been covered up by 600 feet of brackish and fresh water submarine sediment. It is safe to say brackish in general, because in portions of the great valley, as at Livermore pass, brackish water shells have been found in the same formation, while at other places where the tide could ebb and flow, as at Kirker's pass, salt water miocene and pliocene shells are imbedded, the fresher waters farther in the interior.

living near that beach whose mortars did not all get covered up by the waves, to have entitled ancient Cherokee to a town charter.

A New Gear Cutting Machine.

A good circular grinding or gear cutting engine is a tool that is considered almost indispensable in every machine shop of the present day. While improvements have been made in almost every tool in common use, there seems to have been no change for the better in the construction of circular gear cutting machines until recently. The newly invented Peer gear-

PEER'S GEAR CUTTING MACHINE.

terior having destroyed, in the upper beds of the tertiary, the marine and brackish water mollusks that flourished there when the lower and the underlying cretaceous strata were deposited.

The formation of Oroville and Dogtown Table mountains extends over hundreds of

cutting machine, herewith illustrated, has an expansive rotating cutting tool, whereby all classes of gear wheels can be cut on the same machine, dispensing with the several tools employed for that purpose. The machine is so constructed that it can be adjusted in a few minutes for all kinds of work, whether bevel,

SLUICING IN A RAIN STORM.

square miles, as far into the interior as Shasta county, and consists of sandy clays and gravels horizontally bedded and generally conformable as near as the eye can make out to the underlying cretaceous.

The particulars concerning the ancient beach dwellers of Cherokee, belonging to the formation just described, are published in the "Overland Monthly" for July. It is only in consequence of the fact that the streams of that vicinity, Dry creek and Cherokee ravine, have cut through the volcanic capping, and exposed in Mesilla valley a fine geological section through the entire tertiary series, beginning with the surficial strata on top, to the coal at the bottom, including a portion of the cretaceous, that hydraulic mining is rendered practicable along the edges of the mesa, and that ancient Cherokee was ever discovered.

Probably fifty of these mortars have been unearthed at Cherokee. They are too common to be of any value, or to be a curiosity there. Allowing one stone mortar for each tribe or family, there must have been people enough

This machine was patented by John A. Peer, of No. 32 Fremont street, in this city, through the MINING AND SCIENTIFIC PRESS Patent Agency. The little brass model which was made, turned out handsome little brass gear wheels as perfect in shape as could be made in any way. The machine, no doubt, will greatly cheapen the manufacture of all kinds of gear wheels, as in a few minutes it can be adjusted to the smallest and to the largest wheels, and is not liable to get out of order. It does its work perfectly true, and is so simple that any machinist or pattern maker can operate it. Instead of three cuts, each is finished by one cut and one adjustment, giving the proper draft for moulding. Instead of the ordinary solid milling tool, the Peer machine has an expansive rotating cutting tool. The follower which holds the cutting tool has the form of the pitch line on one side, the cutting edge of the tool being made to correspond with that of the follower, with a slight projection for clearance. Any machinist can shape the cutting tool in a few minutes; as the cutting tools wear, however, an ingenious device keeps them adjusted to the work. All kinds of wheels can be cut vertical or horizontal without removing the work from the center upon which it is turned, and the tool is passed through only once to complete each cog. One machine will cut patterns for wheels of all sizes, or dress cast iron wheels taken from the sand.

With one of these machines a bed twelve feet long can swing a wheel sixteen feet in diameter in making patterns. The scale is graduated by eighths from one-quarter inch up to four inch pitch. Mr. Peer says he can make clock or watch wheels equally true with machine wheels; rack-bars and fluted rollers of every degree of fineness, and many other kinds of work too numerous to mention can be made. Wheels of brass or wood, twelve inches or less in diameter, are cut from the solid block more cheaply, and in less time than would be required to make the drawings, besides saving the cost and time of making patterns. In swift running machinery, where one wheel of wood meshes in with another of iron of like diameter, the endurance is increased, and the noise and jar incident to iron gearing in iron is greatly diminished. These wooden wheels are secured to the shaft by two flanges clamping the wood. This machine makes mitre gear of a solid block of hard wood cut upon its end, and heavy wooden wheels, after the cogs are mortised in the usual way, are cheaply and perfectly finished. The followers are standard, and the pitch-line is preserved, so that the wheels can be duplicated without samples or drawings. This machine can be seen at work at the address given above.

Sluicing.

The accompanying engraving will give to those of our readers not familiar with placer mining an idea of what placer miners have to endure in working during the winter storms. It will also, perhaps, bring back to the minds of many memories of early days in the mines, when money was more plenty than it is now-a-days. Standing up to the knees in muddy water and pitching gravel into a dripping sluice overhead is not much fun at any time; but when it is accompanied with a pelting rain storm the discomfort is rather increased. But when the water is plenty and the dirt rich, these little inconveniences are overlooked, and the hardy miner rejoices at the rain and only wishes it to continue. Little of this class of mining is now done in California, the shallow placers being mostly worked out and those that remain are principally worked by Chinamen.

THE "Cromer" is a new location a short distance north of Gold Canon, over the first range of hills and immediately below the Devil's Gate. A shaft is sunk to the depth of 60 ft, at which point the ledge is 8 feet wide, and is being taken out for milling. Assays indicate that it will mill \$40 or \$50 to the ton.

At the Utah mine, on the Comstock, the new and powerful pumping machinery is nearly all in place. The pump columns for the first lift of 275 feet, will be 14 inches in diameter, and will be capable of hoisting a small river of water, when once in full operation.

CORRESPONDENCE.

Australian Notes.

(From our Regular Correspondent.)

Messrs. Editors.—Continuing my description of the various Australian colonies, I arrive at Queensland, which, though inferior in point of area and population, as well as in other matters, to the provinces of South Australia, is yet superior to it in point of revenue, numbers of live stock, etc. This, although the youngest branch of the Australian family, is progressing so rapidly, and has such a solid basis on which to rest that I should not be surprised if in another quarter of a century she were to take first or second place. It is only a few years since she separated from the mother colony of New South Wales, and now she seems to progress at a more rapid rate than any of the group. This, of course, is partly due to the enormous amount of unsettled territory within her borders.

On referring to the map you will find that this colony lies immediately to the north of New South Wales, and embraces the whole of the north-eastern quarter of the Australian continent. On the eastern coast, as might naturally be expected, there are a number of sea-ports which, like those in New Zealand, are not of very great extent at present, but which, like them, will no doubt increase in size and importance as the years roll on and the surrounding country gets permanently settled. The capital city is Brisbane, situated on a river of the same name, not very far north of the New South Wales boundary. The principal part of it is built on an alluvial flat jutting out into the river. You will gather from the comparatively limited population, and the fact of its recent settlement, that the city is not a large one, nor its buildings very substantial or elegant. Nevertheless it has its advantages in the eyes of intending emigrants, inasmuch as its prosperity is indicated by the fact of there being scarcely a house to let in the place, whilst comfortable accommodation for travelers is exceedingly scarce.

A somewhat similar description would answer for the towns of Ipswich, Maryborough, Rockhampton and Bowen, only that they have a smaller population. This is the colony where sheep herders—squatters, we call them—can still obtain leases of stations of enormous size. I heard lately of two young men who recently left Victoria obtaining a tract of 300 square miles, and that at a comparatively nominal rental. Of course this is not in the richest or most accessible part of the colony, but that it can be obtained anywhere is a fact that speaks volumes. There is, about seventy or eighty miles inland from Brisbane, an immense undulating table land, called the "Darling down," where the soil is said to be of the richest kind, and of fabulous depth. This, I need hardly say, is all taken up.

In addition to the immense extent of country suited for pastoral and agricultural purposes, there are vast tracts which competent authorities say contain innumerable gold bearing reefs, requiring only time, patience and money to develop them. A payable tin mine has already been discovered and profitably worked, whilst the Peak Down copper mines have been a success. Timber is present in such quantity and quality that I am informed by a gentleman in the Melbourne timber trade there is no pine imported, a native substitute having been discovered. Cedar trees of fair quality abound on some of the rivers, measuring in some cases fourteen or fifteen feet in diameter.

The cultivation of the sugar cane has been here largely entered into, and some of the oldest colonists think that this will form one of the staples of the country. Already I believe the trade has reached to the extent of some 5,000 tons of sugar per annum, and its only limit seems to be the obtaining sufficient cheap labor. At present they use Kanaka labor, imported from the South Sea Islands, but the supply is limited, and their introduction is looked upon with great jealousy by Great Britain. Coolie labor seems to be the only suitable kind obtainable, and about this there is, as every one now knows, a great deal of difficulty.

Queensland has a patent law, which it derived from the mother colony of New South Wales, and therefore for which it can scarcely be held responsible, although it is of a very objectionable nature, requiring the large sum of £20 to be deposited before the authorities will even receive an inventor's application for a patent. If, however, the patent is once granted, it holds good for fourteen years without any further payment, so that if an invention be a good one, and suited to the requirements of the place, a patent for it is likely to prove very profitable, although requiring somewhat of an effort to pay for it in the first instance. Any invention advantageously affecting the squatter, (wool, hides, skins or meat,) the sugar manufacturer or the miner, should pay well here if judiciously worked. E. W. Melbourne, May 3d, 1875.

Coal Fields of Puget Sound.

From the letter of a correspondent of the *Bulletin*, we extract the following information about these coal fields: A reaction in the right direction has taken place among the leading men of the sound, with the object of developing the resources of the Territory in conjunction with capitalists in San Francisco and elsewhere. The most prominent feature of this development is the unlimited confidence in the vast coal fields on Puget sound. Some facts on this subject will satisfy your readers that this confidence is well founded. The foothills and mountain ranges at the head of

Puyallup Valley

Is discovered to be an extensive coal field, containing immense veins of the finest domestic steam and gas coal. This coal field is located about thirty miles from Tacoma. The Directors of the Oregon Steam Navigation company contemplate building a narrow gauge railroad from Tacoma to their valuable claims there, to connect with the Northern Pacific railroad at Tacoma to Kalama, on the Columbia river. There is no doubt but this is one of the most valuable discoveries of coal yet made on the sound. This railroad will pass through the beautiful and fertile valley above named, that is now coming into prominence as admirably adapted for raising hops to great advantage. The valley is twenty-five miles long by a breadth of seven miles. This coal field will be of great importance to Tacoma as a shipping point for this valuable coal, by sea and land.

The Seattle Coal and Transportation Company has passed through the painful experience of many similar companies in their early attempts to succeed.

The mine is now thoroughly organized, with ample capital and is in good working order, with the reasonable certainty of grand results in the near future. The mine is located seventeen and one-half miles from Seattle, three miles beyond Lake Washington. The shipping point is the bay of Seattle. The coal is brought from the mine to Lake Washington, three miles by railroad; then across that lake ten miles in barges that carry eighteen cars; then a railroad portage of half a mile; then three miles across Lake Union; then a mile of railroad that lands the coal at the depot, where it is either put on board a vessel from the care or placed in the bunker, that holds 1,000 tons. Four round trips are made every day to and from the mine, bringing fifty tons each trip. At present eighty miners are employed and fifty-five outside men, such as drivers, mechanics and laborers. The company pay about \$10,000 a month for wages and improvements. The company have 1,000 acres of coal lands in one body. Two tunnels are opened for half a mile each, and both are in working order; they run in such a gentle incline as to drain themselves. The two veins run for three miles, and have each an average of four and a half feet of pure coal. There are other veins not yet opened, some of them containing seven and others ten feet thickness of coal. There are well defined veins connected with this mine that measure in all thirty-two feet of solid coal, that will take half a century to work out. At the shipping depot there are workshops for making cars, including carpenters, blacksmiths, mechanics and men for putting the coal on board vessels. C. B. Shattuck has charge of the transportation departments, and W. H. Taylor looks out for the weighing and other responsible duties. The improvements inaugurated for the further development of the mine are on an extensive scale. Two large barges are ordered that will carry sixty cars, or 120 tons of coal each; a powerful locomotive is on the way to take the place of a small one at the mine. A large steamer for towing is to be built immediately to take the place of an inferior one, so that by the first of July there will be 300 tons of coal sent out from the mine daily; by the month of August there will be 400 tons, and by October most probably 500 tons, or 3,000 tons a week. The coal is excellent for domestic purposes and very good for steamships, locomotives and furnaces. D. W. Jones is the superintendent of the mine. O. Coeter is the responsible hook-keeper. Captain Jackson has charge of the steamer on Lake Union, and Captain William Bailey is master of the steamer on Lake Washington.

This mining camp is a regular village, containing numerous houses, and quite a number are being built. There will be a hundred more men employed in two months. A well supplied store is kept by the company for the accommodation of the miners and others. Miners are paid \$1.25 a ton; good miners make an average of \$4 per day; carpenters get from \$3 to \$4; drivers get from \$2 to \$3; common laborers get from \$30 to \$40 a month and board. There is a good demand for all these classes of men. Competent, reliable men of good habits can get constant employment and make money. Married men are preferred as being more steady and permanent. The large majority of the men at the mines are single, of a roving disposition—here to-day, away to-morrow—fulfilling the old proverb, "A rolling stone gathers no moss." The gentlemen composing this company are principally San Francisco capitalists. Three vessels are loading coal at present at the wharf for San Francisco, that will average 1,000 tons each.

The Renton Coal Mine

Is located on Cedar river, a mile from the head of Lake Washington, and the same distance from the mouth of Black river, on the divide between Cedar river and White river. The mine

was commenced to be opened about twelve months since. Fifty miners and others are employed. Seventy-five tons of coal are taken out daily, put into a bunker and screened as they descend; then they are put in cars from the bunker, sent by rail two miles to Black river, put on barges, and towed by steamer down Black river into Duwamish river, thence to Seattle and put into a large bunker on the wharf, that holds 1,200 tons, to be shipped to San Francisco as vessels arrive, three of which are daily expected. The distance from the mine to Seattle is twelve miles. The main tunnel was opened 600 yards two months ago; since then ten rooms have been opened. The vein of coal now being worked is seven feet thick of solid coal. The coal ranks among the best for domestic purposes and is well liked for raising steam.

By the first of July the company will be in a position to ship 100 tons a day. The claim contains 730 acres of coal lands. Some of the veins, so far as known, are better than the one opened. The company is a joint stock one, known as the Renton coal company. It is composed of a numerous list of shareholders, who are entitled to a certain quantity of coal yearly, in proportion to the number of shares that each holds, at eight dollars a ton, in addition to the dividend on the profits of the company. The directors and shareholders are all San Francisco people. The mining camp is a little village composed of numerous cottages for the men, a large dining hall, a good store, comfortable quarters for the superintendent and hook-keeper. The company have a profitable saw-mill, own five barges and a steamer for towing. To all appearance the mine is in a healthy condition, and the prospects decidedly favorable. Mr. Robins is in charge at present as superintendent, and W. C. Dripps is the confidential hook-keeper. A stage from Seattle runs to the village every morning and returns in the evening, charging two dollars for the round trip.

The Talbot Coal Mining Company.

This mine is on the same divide as the Renton mine, between Cedar and White rivers, and three-quarters of a mile from Black river. The mine was opened early in November; 225 feet of tunnel were cut before coal was struck. The tunnel is now 535 feet long; twenty miners are employed and sixteen outside men; 600 tons of coal are in the bunker ready for being forwarded to Seattle for shipment to San Francisco. The coal is taken from the mine to the bunker in cars by rail a third of a mile long, then from the bunker to Black river, a short distance, in cars, put on barges and towed to Seattle by way of Black and Duwamish rivers, twelve miles in all. The company owns 320 acres of coal lands. The tunnel opened has a vein ten feet thick of pure coal of the best kind for domestic uses and steam purposes, as well as for ordinary blacksmith work. The company is composed of Messrs. John Collins, John Leary, James McNaught and Michael Padden—all Seattle men. Mr. Padden is the superintendent of the mine. The substantial and economical manner in which the work is done proves the superintendent to be the right man in the right place.

Cedar Mountain Mine

Is located on the same divide as Renton and Talbot mines, six miles above Renton mine, and, like it, near the margin of Cedar river and running into the mountain that forms the divide. It has only been partially opened as yet, but there is no doubt that it contains an immense quantity of coal of a superior kind. The vein shows a thickness of coal from nine to twelve feet in different places. There are 220 acres of coal lands connected with the mine. The mine has been lately purchased from Messrs. McAllister and George, of Seattle, by a San Francisco company, for \$25,000. It will form a valuable contribution to the coal business of Seattle and Puget sound. Active operations will commence for opening the mine as soon as it is settled that the Seattle and Walla Walla railroad is to be built that far. There is every reasonable certainty that that road will be built twenty miles this summer, extending to the outside limits of this mine. The road is already graded seven-eighths of the twenty miles. When built it will give an immense impulse to the coal trade and other enterprises in and around Seattle. Should it be built this summer there will be 1,000 tons of coal sent from these mines to Seattle daily for shipment, or 300,000 tons a year; 750 men employed in working them, and that will only be the beginning of the future grand development of this important industry extending along the whole line of the sound.

The Clymer Mine

Is located near the junction of Cedar and Black rivers, a short distance from the head of Lake Washington. It is an old mine, but was never worked to advantage. Dr. A. Bagley and Messrs. A. Treadwell, J. R. Robbins and S. P. Andrew have lately bought the mine from C. Clymer, the latter retaining a share. They are all Seattle men, and have commenced in earnest to open the mine and work it effectively. There are 340 acres of coal lands owned by the company. The tunnel is not sufficiently opened to form a correct opinion as to the thickness of the vein. The owners claim that there are seven feet of solid coal in the vein. When the Seattle and Walla Walla railroad is built the first twenty miles, this company will have ample facilities for sending their coal to Seattle for shipment.

Other Coal Mines.

There are four other coal mines on Stillagna-mish river, and one on Snohomish river not

yet worked, that are extensive, and valuable coal for common house purposes. On the Skagit river a most valuable coal mine has been discovered, and is partially wrought by six miners, in which J. J. Conner, of that place, has an interest. It has been fully tested that this coal is equal to the famous Bloesberg and Cumberland coal for blacksmiths. The company are now supplying a large number of blacksmiths on the sound with this coal, and will soon be in a position to meet the entire wants of the Territory at moderate rates. Competent judges say the same coal will make the best of gas and coke beautifully. It is a soft coal, and requires to be shipped in bags or barrels. It is obvious to the close observer that there is in this district of Puget sound, from Puyallup river, coming out from Mount Rainier, to Bellingham bay, underneath Mount Baker—a distance of more than one hundred miles—an almost inexhaustible storehouse of the best of coal for almost every requirement of the human family in the shape of fuel. The reflecting mind, when contemplating the future development of these vast coal fields, the mountains of iron, the magnificent forests, and the extensive ship building on Puget sound, can easily foresee a grand development of these industries along the whole line of the beautiful, varied and extensive waters of the sound.

Mariposa Estate.

We have recently made inquiries, says the *Mariposa Gazette*, respecting the grand tunnel enterprise of the Mariposa company on the Merced, and have come in possession of many interesting facts. As long ago as 1858 or '59, Dr. Adelberg suggested the advisability of a tunnel from the Merced river at the Benton mills, along the line of the vein of quartz which was known to exist from the river to the Pine Tree and Josephine mines, and from these last, continuing southwardly, to Mount Ophir, Princeton, Agua Frio, and even to the extreme southerly limits of this estate. The suggestion was not acted on at the time, but some years after was again brought to the notice of the Mariposa company. A tunnel was commenced and then abandoned, and the enterprise was permitted to rest until June, 1873, when the work was in reality commenced.

The tunnel was carried on with occasional interruptions until June, 1874, and then, after a rest of six months, was again resumed, until now it has reached a length of 800 feet. The work at the commencement was easy, but as the drift advanced, the ground became harder, until at 440 feet, hard blue slate was encountered, and has since continued. The course of the tunnel being parallel to the stratification, in blasting the powder loses seventy-five per cent. of its effective force on the "centre outs."

Had it not been for the Borleigh rock drill it is almost fair to say that the work would have been abandoned long since, as competent miners estimate the cost of running it at \$70 per foot. With this tunnel once in on the vein, which it is expected to strike at 1,000 or 1,200 feet, the cost of carrying it on will be defrayed out of the vein itself, for, with a down grade to the mill, and absence of handling the ore twice, the quartz can be delivered at the "spaller" for less than \$2 per ton, and the cost of milling will not exceed that amount, as the principal item of expense in milling is done away with, or reduced to a minimum by using the water power of the Merced.

As we mentioned in our last issue, steps are now being taken to bring in a ditch, and we understand that most of the drilling on its line will be accomplished by the Burleigh drill. The ditch, besides furnishing power to the Benton mills, will also supply the means of working the placers above the banks of the river, which are now useless for the want of water. The amount of extra power to be derived from the increased fall, will be nearly 1,000 horse-power. And it is part of the policy of the Mariposa land and mining company to utilize this power by milling the quartz furnished by the series of veins from the Merced river to Agua Frio, thus avoiding the enormous expense for fuel of about \$20,000 yearly for each mill. Thus at no greatly distant day we shall see Princeton rock going its winding way to the Merced!

We have by no means lost faith in the future of this splendid property, on which, as yet, comparatively speaking, only a few scratches have been made. The future stands before us, and under the new regime it promises to be a grand one.

MINEING STRIKE.—"An important mining strike," says the *Silver City Times*, "was made on Saturday in the Amazon mine, which adjoins the Genesee and Alhambra on the south. The drift struck a rich body of ore, which, in color and character, can hardly be distinguished from that of the Consolidated Virginia. Yesterday morning the drift had cut four feet into the vein, and the face was still in splendid ore. The strike created considerable excitement, and many are of the opinion that we are to have a genuine bonanza on this end of the great lead." A letter from the mine states that the vein is full seven feet with blue clay walls.

PRESERVATION OF ROPE.—The following process for preserving rope has been patented on the Continent: The rope is steeped in a solution of 600 grammes of sulphate of copper, 200 grammes of sulphate of zinc, and thirty grammes of glycerine evaporated to dryness, the whole mixed with twenty-four litres of boiling water in a close vessel.

SCIENTIFIC PROGRESS.

Some Recent Observations on Magnetism.

In our last issue we gave, from *Iron*, an account of some recent and interesting observations in regard to magnetism. We continue the subject in the present issue as follows:

In Professor Helmholtz's laboratory at Berlin, M. Holz has recently been studying the causes of variation in magnetic coercive force (see *Pogg. Ann.*); examining the magnetic properties of iron bars obtained by the electrolytic method, and comparing with steel bars. He finds that the former, through heating, acquire a greater specific gravity; the molecules are less apart, and the permanent magnetic moment is diminished nearly a half. Steel bars, on the other hand, acquire a less specific gravity through heating and hardening; the molecules are further apart, and the magnetic moment is considerably increased. This change of magnetic force, arising from change in density, readily explains (as M. Holz points out) the effects observed by M. Wiedemann in studying the relation between magnetization and torsion. He found that the permanent magnetism of steel bars decreases through torsion; that the temporary magnetism increases through detorsion; and that iron bars cut with a hawk saw are untwisted by magnetization. Now, torsion condenses the bar, so the magnetism must decrease, owing to increase of the specific gravity. Detorsion has the opposite effect, and in magnetizing the iron bars referred to, an expansion must take place which results in detorsion.

Coercive force is, doubtless, to be regarded as a passive force, like friction, hindering the movement of molecules in any direction, and it seems natural to suppose that its intensity will diminish when the temperature is raised, the heat favoring magnetization when the magnetizing force is superior to the force which tends to bring the molecules to their position of equilibrium; and demagnetization, when the molecular force is superior. Supporting this view, M. Gangain states, in one of his interesting series of notes on magnetism to the French Academy, that he has been able to increase magnetism, under certain conditions, by means of heat. He first magnetized small bars of steel, keeping them a few instants with one end in contact with one of the poles of a permanent magnet. He then ascertained their magnetic state (by his special method); then he renewed the contact, and heated them with a spirit lamp; put out the lamp and let the bars cool before detaching them. He then found the magnetization much greater than when the bars had not been heated. The increase of magnetism only takes place if the bar remains in contact with the magnet while cooling. The total magnetism (as well as the permanent) was considerably increased by the heating, but the magnet had only to be removed a few seconds for a portion of this increase to disappear.

It is known that some specimens of native platinum not only act on the magnetic needle, but are magnetipolar, like true magnets. The auriferous sands of the Oural, after some washings, leave a residuum in which gold is associated with ferruginous substances. To separate the latter (at least in part) the workmen use a natural magnet of magnetic oxide of iron got in the mine of Blagodat. Now, after this magnet has ceased to act, a magnet of native platinum will further extract ferruginous grains in considerable quantity. Analysis of these magnets of native platinum have shown that they always contain iron in considerable proportion. M. Rose thought the iron alone was insufficient to account for the effects, and that they must in part be due to the iridium present. The subject has been recently gone into by M. Dautree. He has succeeded in producing these magnets artificially by electrolysis; in which he fused platinum with a quarter of its weight of iron (twenty-four grammes of platinum and six grammes of iron). Polar magnetism appeared very markedly in the cast, and in the fragments of this when it was broken. The remarkable point is that only certain proportions of the two metals give the desired result. M. Dautree made an alloy of ninety-nine per cent. iron and one per cent. platinum, but this, though strongly magnetic, gave no traces of polarity. And, on the other hand, native platinum containing only a small proportion of iron is also not magnetipolar. Further, several minerals called magnetic may be made magnetipolar by certain operations; but in the case under consideration the magnetipolarity appears immediately in the alloy, whenever the cast is sufficiently cooled, and without any touch, simply under the inductive action of the earth. The phenomenon is one which is worthy of further investigation and has some practical importance.

M. Chautard has lately observed some striking changes in the spectra of the metalloids when the gases (in Geissler tubes) were put under the influence of strong electro-magnets. The light of sulphur and selenium undergoes considerable diminution of intensity, so great, sometimes, that the spectrum, which is not very bright at the beginning, entirely disappears after a few seconds. Chlorine and

bromine, on the other hand, show an increase of brightness, under the action of the electro-magnet, and there is a development of numerous fine bright lines, especially in the green. These facts the author considers important in reference to cosmic spectroscopy and the obscure relations between magnetism and light.

The New Glass—Another Process of Producing It.

It is announced that Mr. Charles Pieper, a German inventor, has devised a way of toughening glass, which the German papers pronounce superior to that of M. de la Bastie, already described in these columns. The Pieper glass is said to be fully as strong as that of the latter inventor, and its appearance is much purer and clearer. Extended experiments upon it have begun in Germany. The Association of German Glass Makers has already entered into negotiations with Mr. Pieper for the use of his invention, suspending similar dealings with M. de la Bastie, on account of the immense price asked by him, over eight million dollars.

Hardening Glass.

In connection with the above the following will be read with interest: A process of hardening glass has been patented by Mr. Macintosh, of Westminster, Eng., a civil engineer who has devoted much time and attention to the hardening of iron, steel and alloys. Starting on the broad ground that, the lower the degree of temperature of the liquid in which certain heated bodies were plunged, the harder such bodies became, Mr. Macintosh has found that glass, graphite, uncrystallized carbon, slag and other analogous substances may be rendered exceedingly hard by means which are usually indicated for metals. Colored glass may, by this treatment, be rendered so hard as to be effectively used as a substitute for gems, and, what is curious, may be pulverized and used in the same way as diamond dust or emery powder.

In hardening the substance, the method pursued by the patentee is to place a small quantity of fused or nearly fused clear or colored glass in iron or other molds to shape the glass, and the substance is taken out of the molds and placed in platinum molds, and fused or nearly fused, and suddenly deprived of its color by frigorific mixtures of iced water and salt, or any of the freezing compounds that produce extreme cold; the sum and substance of which is that the glass is heated to a very high degree of temperature and then rapidly cooled in a very frigid fluid. A startling statement is made by Mr. Macintosh when he asserts that when the component parts of gems are treated by the above process, he is enabled to produce thereby fictitious gems even harder than real diamonds.

Curious Experiment in Instantaneous Crystallization.

It is well known that various salts dissolve in water in different proportions, and that the solution usually takes place more readily when the water is warm. After cooling, crystallization of the fluid takes place, but this may be prevented by leaving the solution in absolute quiet and protecting it from contact with the air. It is then said to be supersaturated, and the least shock, or the addition of a minute crystal of the salt, is sufficient to cause instantaneous crystallization of the whole. A curious experiment, based on the above, has recently been devised by M. Peligot: 150 parts, by weight, of hyposulphite of soda are dissolved in fifteen parts water, and the solution is turned into a large test tube, previously warmed, so as to half fill the same. Another solution of 100 parts, by weight, of acetate of soda, in fifteen parts of boiling water, is made, and this is carefully poured in on top of the first solution, so as to float on and not mingle with the latter. To the above two solutions is then added a little boiling water, and the whole is left in quiet to cool.

After the cooling is accomplished, a little crystal of hyposulphite of soda may be let down into the liquid. The fragment will traverse the acetate solution without effect thereon; but on its reaching the solution below, instant crystallization of the same will take place. As soon as the re-action in the hyposulphite is finished, a crystal of acetate of soda may be added to produce a similar result in the acetate solution.

A NEW ARTIFICIAL LIGHT FOR PHOTOGRAPHING.—The following is a description of a new artificial light for photographing, which has been recently invented in France. A quart bottle, with a somewhat large mouth, has a cork with two openings. Through one of these a tube passes to near the bottom of the bottle; through the second a larger tube, packed with iron scale, issues. Fragments of prussic acid are poured. A current of nitric oxide prepared by Deville's method—by the action of nitric and sulphuric acids on metallic iron contained in a self-regulating reservoir—is passed through the bottle, where it takes up the vapor of the disulphide. It is then led through the safety tube packed with iron scale to the burner. Excellent photographs were taken in five seconds with this light, the object being six feet distant. In photographic power the light is asserted to be superior to the magnesium or calcium light, and even to surpass the electric light itself. The products of combustion are noxious and must be got rid of.

A NOVELTY IN ORNAMENTAL SILVERING.—In Munich various objects of art have lately been displayed which are remarkable for their brilliant silver hue. It appears that they are mere plaster models covered with a thin coat of mica powder, which perfectly replaces the ordinary metallic substances. The mica plates are first cleaned and bleached by fire, boiled in hydrochloric acid, and washed and dried. The material is then finely powdered, sifted, and mingled with collodion, which serves as a vehicle for applying the compound with a paintbrush. The objects thus prepared can be washed in water, and are not liable to be injured by sulphuretted gases or dust. The collodion adheres perfectly to glass, porcelain, wood, metal, or *papier mache*. The mica can be easily tinted in different colors, thus adding to the beauty of the ornamentation.

MECHANICAL PROGRESS.

The Cold Steam Motor.

We have made several allusions to what is claimed by a Philadelphia inventor as a new motive power which is to supersede steam, by virtue of its being far more powerful and very much cheaper. It is claimed that its cost is a mere trifle, compared to the cost of steam, while it is capable of being used with the utmost safety at a pressure many times that of the ordinary use of steam.

The discoverer refuses to tell, even the capitalists associated with him, how he obtains his power; although he freely permits his associates and some of their friends, as experts, to see the machine both at rest and at work. According to reports, they find that it actually possesses wonderful power, developed in a manner which they cannot explain. They have taken the machine to pieces, watched the discoverer, Keeley, while putting in water and blowing in air, examined the vapor which issues from the machine when in operation, and found that the power amounts to a pressure of several thousand pounds to the square inch. There is no fire, no heat, and, so far as they can discover, no chemical; and they suppose that the power is obtained by decomposing water into its constituent gases by some process not generally understood. Keeley says he must keep his secret till he gets his patents. He refuses to give a name to the motor; but others, led by guess, call it "cold steam." The machine is described as about three feet high, two long, and a foot wide; and contains a number of pipes of wrought iron connected by valves. It has been seen at work by Mr. Rutherford, Chief Engineer of the United States Navy, and he, with others, signed an opinion which has been published in a pamphlet for the use of the stockholders.

We understand that neither Mr. K. nor the parties associated with him desire to part with any stock in the invention, and they express the belief that within a short time trains will be driven by the new motor on some one or more of our principal railroads. While mechanics and others are on the tips of expectation, all prefer to wait for a practical demonstration, on the principal that only seeing will lead to full confidence in the reality of the invention.

Pottery in the United States.

For the manufacture of pottery in the United States there is no lack of the very best material, and indeed there is no good reason why we should be dependent upon foreign sources for a supply of any kind of fine work. We can, at least, maintain a respectable antiquity here, for at the Delaware Water Gap specimens of cups, of early Indian work, of good form and rudely decorated, have been washed out, with stone implements. Wedgewood used clay from Georgia and Florida, and was quite jealous of the "pot works" in South Carolina in 1770. We had porcelain works in Philadelphia at that time, too, and again in 1849, but they were not sustained, although Phoenixville is doing its best to establish a factory there. Pennsylvania reports 198 establishments for the manufacture of stone and earthenware, the highest number in any state. Trenton has twenty potteries and sixty kilns, producing stone china as good as any imported. In Jersey there is an abundance of good clay from Camden county to Raritan bay. In Chester county there are establishments for mining, washing and preparing kaolin, a fine clay, equal to any from Cornwall in England, and on the Susquehanna there are mills to crush and grind fine quartz and feldspar rock, the material need in the manufacture of pottery. The decoration of our home ware is going on finely, and in time we may hope to gain artistic culture and inspiration to rival our progress in other branches of useful manufactures, and learn to depend upon our own workmen to utilize the material which lies within our own borders, instead of importing or merely imitating the products of foreign workshops and designs.

The pottery business of California is gradually becoming an important industry. The pottery clays of the State seem to be gaining favor. The deposit found in the coal beds on the northeastern slope of Mt. Diablo has been used for years, and an extensive establishment has recently been put up at the Lincoln coal mine, where equally good material for earthenware has been found. As yet, only the coarser articles are made, but with time we may hope to see large factories of porcelain in California.

The Sand Blast—New Applications.

The sand blast has, in the four years it has been in operation, wrought a revolution in all kinds of ornamental stone cutting. For cutting glass the pressure of an ordinary blower is sufficient to make either a plain, uniformly depolished surface, or copy the most delicate line engraving; while for stone and metal cutting a pressure of from 90 to 100 pounds is employed. The contractor for furnishing 250,000 head stones to the government employs the blast; and by its use completes them at the rate of 300 per day, averaging eighteen letters each.

One great use of the blast, at present, is in the manufacture of plain and colored glass signs, of all descriptions, as well as door lights of most artistic and beautiful designs. It is also beginning to be used in lapidary work of all kinds, especially in the manufacture of initial jewelry. It is also employed very largely in giving the popular "satin finish" to silver-plated ware, and, more recently, to the manufacture of glass globes, bearing elaborate and artistic patterns.

The Ames shovel works, at Taunton, Mass., are proposing to apply the blast to the cleaning of their iron from rust, etc., a process now attended with considerable labor and inconvenience. A Taunton (Mass.) tack factory, which cleans 17,000 square feet of tack plate per diem, is also proposing to apply it to the same purpose. One of its most novel applications was the recent furnishing of 200 appropriately engraved glass cards, for the glass wedding of an eccentric Englishman. Some twenty tons of five-eighth inch glass for the dome of the New Orleans custom house were recently cleaned and depolished. Such thick glass is always full of little specks of dirt, etc., on its surface; but by the use of the blast a perfectly clean surface was obtained, which transmitted a clear, pleasant light.

A New Carriage Wheel for the Road.

A new principle in the construction of carriage wheels has just been patented by Mr. Robert Pooke, of Birmingham, which is exciting some attention. In this new wheel every part consists of wrought iron, with the exception of the tire, which is formed of the best cast steel. The method of fastening the spokes (which are hollow), both in the rim and in the boss, is as simple as it is safe. The tire is constructed so as to protect the other parts of the wheel when it runs against the curbstone, or comes in contact with another vehicle. Neither in putting on the tire, nor indeed in any portion of the work, is a single bolt or nail employed, the spokes being slipped into their places in the rim and boss, and afterwards locked up by a nut, while the tire is firmly inserted into a groove in the rim. The patentee has likewise made considerable improvements in the axle-tree and boss, the strength of the former being increased at the points where it is most liable to give way, and the latter possessing accommodation for about four times the usual quantity of oil for lubricating purposes. Although made of iron and steel, each wheel is not more than two or three pounds heavier than ordinary wheels, and the cost of production is about the same in both cases. The objects aimed at by the inventor have been the light appearance and strength of the wheel as well as simplicity in its construction; and in these respects he has been highly successful. —*British Trade Journal*.

A GREAT IMPROVEMENT IN NAIL MACHINERY.

—The Cincinnati *Enquirer* says of the Haddock nail machine, that it is one of the most wonderful mechanical inventions ever introduced, that it will revolutionize the nail-making business, that the machine manufactures 25 per cent. more nails, at a saving of over 50 per cent. in labor, than any other machine in use. Quite a number of heavy capitalists have taken stock in the company, which shows their faith in the enterprise.

NEW BARREL MACHINE.—It is said that Mr. J. W. Jones, of Wheeling, W. Va., has invented a crozier that cuts, grades the thickness, squares the ends, chamfers and grooves a stave at one stroke. One machine is capable of turning out in a day eight hundred "etands" of staves, or kegs, the labor required for feeding being that of a boy only. It is automatic, in fact, and is a self-feeder to a great extent.

BENDING VS. FORGING.—It is now possible by the aid of hydraulic machinery to bend iron shafts of twelve inches diameter, when properly heated, to any required shape. The bent shafts are said to be better than forged ones, from the fact that the fibre of the metal runs in one direction continually, whereas in forged ones it is often across the line of strain.

RAPID WORK.—John Add, an ingenious inventor of New Haven, Conn., has invented and is now manufacturing a machine which will cut, bend and finish 500 staples a minute. It will take but few such machines to make all the staples needed in the country.

STAMPING MOLD BOARDS.—Mold boards for plows are now stamped at a single operation, in a press.

mine is yielding its customary rich rock. They are engaged in crushing a few loads of ore which will pay to the tune of \$10,000. The owners are also opening another lead at Skull Flat which promises quite as well as the Champion.

THOMPSON MINES.—This mine, since coming into possession of a new company, is being worked as formerly, owing to the anticipated failure of water soon. We understand that during the summer all preparations will be completed for sinking the main shaft an additional 200 ft. This is what the mine wants, and experienced miners are confident that, properly developed, this mine will prove one of the most permanent in the State.

INYO.

HAPPY VALLEY.—Panamint News, June 15: For a commencement to our report this week of the Panamint mines we will take our readers over into Happy valley to look at mines there. The Dempsey, owned by Tipton & Cannin, is situated near the head of the canon and about a half a mile northwest from the Handsou River, owned by the S. V. M. & W. Co., and is one of the oldest locations. For the amount of work done upon the Dempsey, it is showing up finely, and gives promise of being one of the leading mines in the district. The vein is from 12 to 20 ft in width; the ore is of the black sulphur character, and will assay \$60 to \$500 per ton. A good force of men are now at work in tunneling and cross-cutting the vein.

THE SURPRISE. one of the two lately bonded by E. P. Rains for \$100,000, is looking even better than was expected. We were shown a piece of ore taken from this mine a day or two ago which will probably weigh 35 pounds. It is one of the very finest specimens of black sulphur and chloride ore we have seen in this district, and is certainly good enough to dispel any doubts the best of critics may have in the richness of our ores. Since our last report (June 1st), the tunnel has been run in 10 ft further, making its total length 35 ft. The mountain at the point where the tunnel is started is almost perpendicular, and from the opening to the top, a distance of 125 ft, good ore is shown to the top, and for the whole length and width of the tunnel. The tunnel is in the vein, and is five ft in width by six ft in height. The vein, however, is at least 10 ft in width, and ore is seen all through the tunnel without a skip. The ore is considered to be worth and will work at least \$400 per ton. About 40 tons of this class of ore have been taken out from this tunnel.

From this point, for a distance of 2,000 ft, the croppings are plainly discernible, and are bearing for the whole length to the working point on the North Star, the other mine bonded by Mr. Rains in connection with the surprise, and is on the same ledge. This mine shows a vein 20 ft in width at the bottom of the canon, 1500 ft in depth, where a tunnel has been run in a distance of 60 ft, thus accomplishing in a few weeks, in the way of exploration, what it took years to do on the great bonanza mines of Virginia City. These two mines alone, if properly worked, are sufficient for themselves to make this a prosperous camp. Mr. Rains having gone below to perfect arrangements for the immediate inauguration of work upon these valuable mines, Messrs. Tipton & Cannin have been surveying for and had that as good a road as that leading up Surprise canon can be made at an expense not to exceed \$7,000 or \$8,000. The road will start from the head of Happy Valley canon and terminate at the main road in Panamint valley, about two and a half miles south of the mouth of Surprise canon. Men will immediately be set to work constructing the road.

Good mill sites have already been located, and as there is an abundance of wood and water there the probabilities are that Happy valley will prove a formidable rival to Surprise canon.

LAKE.

THE GREAT WESTERN MINE.—Russian River, June 17: Among the prominent quicker miners of this part of the state is the Great Western. It is located in Lake county, miles south of Middletown and 9 miles north of the new town of Kellogg, in Knight's valley. There are 8 tunnels in the mine, aggregating not less than 5,000 ft in length. The longest runs 800 ft along the ledge; the lowest about 275 ft below the surface. The ledge is from 10 to 64 ft wide and contains but little rock fit for the furnace. The most of the rock is so decomposed that it crumbles on being taken out and exposed to the air, so that it is necessary to make it into adobes for setting. The mine is opened well and is in working order. But little stopping has been done, and yet 10,000 tons of ore has accumulated on the dumps. With a 10-ton Luckhardt furnace and a 35-ton Green furnace the mine has yielded 1,800 flasks of metal in the last six months. Another Green furnace is about completed and the Luckhardt will be taken down and replaced with a Green furnace this summer. There will then be three Green furnaces, with a combined capacity for melting 105 tons of hard rock, or 120 tons of bessemer, every 24 hours. The mine gives employment to 15 white men and 170 Chinamen. There is a store and a butcher shop at the mine; a postoffice and a telegraph office will soon be established. The company own 1,500 acres of heavily timbered land about their mine, on which there is a steam sawmill that supplies the mine and the neighboring mines with lumber. The mining locations of the company comprise 30 ft of ground, but the most of the devel-

opments have been made at the northwest end, as the vein grows richer as it goes northwest. This fact leads the owners of an adjoining claim (an undeveloped location called the "Northwest") to expect to find as rich a deposit of ore as is now being worked in the Great Western.

MARIPOSA.

THE NORTH END.—Mariposa Gazette, June 19: From a friend who recently came through the Mariposa estate from Merced to this place, we learn that since he was there, eight months ago, the aspect of the place has entirely changed. At the first visit the neighborhood of the mills, on the river, was the "city of the dead," but now the busy hum of workmen is heard and the pleasant click, click of the air compressor, as it drives the energetic little drills 1,500 feet away.

BEAR VALLEY is looking up, the inhabitants of that pleasant little village already feel better than they thought possible a year ago. There is no doubt but that the mining interests of this county are the foundation of our prosperity, and if they are successful the other interests are bound to have a healthier tone. We have no doubt of the immense wealth under our feet, and live in the firm belief that we shall again see Princeton and Mariposa yielding their golden treasures. The only road to success is by a systematic course of mining, and that, aided by honest, watchful, economical management in all departments, from the highest to the lowest, will place the Mariposa land and mining company among the pinnoely corporations of the world.

NEVADA.

ARGENTIA.—Foothill Tidings, June 19: This extension claim on the Pittsburg lode is to be opened at once by tunnel; a contract for driving 500 ft having recently been let. The Pittsburg itself is better and better as depth is attained, the ledge being now of good width, solid, and paying well.

KENTUCKY.—Black cab rock all cut out, walls coming into proper shape for permanency, quartz looking well and on the whole the prospect looking better than ever before in the history of the mine. Such is a brief statement of the condition of the Kentucky yesterday, as drawn from conversation with several miners who work in and about the mine.

EMERALD.—This old mine, since it came under the management of Mr. David Watt as superintendent and Mr. James Bunnelleck as foreman, has gone steadily forward toward its ancient standing among the big paying mines of Gras Valley. On Tuesday a dividend of 50c a share was declared and last month the mill turned out about \$25,000 worth of bullion from less than 1,000 tons of ore. This is one of the best constructed and closest working mills in the State and the mine, which has been worked for about 22 years past, bids fair to continue its usefulness many years longer.

The sale of the Yuba mine and mill, above Washington, which we spoke of as on the tapis last week, has been consummated, and the property passes into the hands of the new owners and under the charge of Mr. Geo. Lord as superintendent, to-morrow. The principal owners now are Messrs. John and Edward Coleman, John Polgase, George Lord and D. N. Coffin, though there are several others who wished for and obtained a slice in during the pendency of the trade.

NEW YORK HILL.—Latest official information from this mine is to the following effect: The mill will be ready to start up crushing in 10 or 15 days. The rock in the main shaft is very hard, consequently sinking progresses slowly. The ledge in the drift east from the second level has excellent quality of ore and stopes west are looking excellently well, ledge very strong. The upraise, 89 feet from the tunnel, is in excellent ledge matter, showing heavy sulphur and gold freely. Next week a winze will be started from the upper tunnel to meet the upraise from the lower tunnel. This will improve the ventilation and also open out a large pay chute. During the week 65 tons of ore were raised, leaving on dumps, 167.

PLACER.

Mining.—Placer Argus, June 19: Messrs. Carroll and Duke are now working over Auburn ravine, from which they expect to get good pay. Several pans have been washed which proved to be quite valuable in colors. It has been about twelve years, we are informed, since it was washed over the last time. Whether these gentlemen make it pay or not, the cleaning out of the ravine will certainly be a benefit to the town, as the accumulated filth of a dozen years is immense, and if Auburn was not one of the healthiest places on the continent everybody in it would be sick. Imagine the stench that must necessarily arise from two or three feet in thickness of old socks, clothing, boots and shoes and all other kinds of rubbish deposited in a place, and the benefit of a general cleaning out will be apparent to every one. We hope they will make each \$20 a day. The gold that has already been taken out of the ravine within the corporate limits of the town of Auburn, is beyond computation or calculation, but it has been sufficient to make many men wealthy, and afford a good business for those who supplied the miners, and has built up the handsome town of Auburn, one of the finest, most picturesque and beautiful on the Pacific coast.

DITCH.—Placer Herald, June 19: The Auburn gravel mining and ditch company have their new ditch completed, the pipe all laid. The big flume on the line of the ditch will be finished next Tuesday, and the ground sluice before the last of the week. This company, and especially Superintendent Hobson, deserve

great credit for the energy manifested in this gigantic undertaking.

THE ST. LAWRENCE QUARTZ MILL. we understand, is kept running steadily. The company are just now mainly engaged in prospecting for the best paying chute, on which, when settled upon, they intend to sink.

It is reported that the chrome ledge has pinched out and work suspended on the mine. The mill at the Greene mine is just now shut down. We understand the suspension is only temporary.

THE JULIAN MINE. on Jenny Lind flat, continues to pay out in paying quantities. The 20-stamp mill is kept running night and day.

PLUMAS.

GREENVILLE MINING NOTES.—Plumas National, June 19: As the working of the Indian Valley mine becomes a little more systematized it begins to yield handsomely. A clean-up on last Wednesday gave \$2,500 for 12 days' run, being a net profit of about \$84 per day. This mine has flattering prospects ahead, and promises to prove a "bonanza" to the lucky owners. The Baker mine shipped \$800 this week. The Greenville mine was cleaning up when our dispatch came, with better prospects than ever before for the past two years. The Wolf creek company will have their new steam stamp mill ready to commence crushing quartz by Monday next, when we expect to hear of some rich strikes. Wolf creek is an entirely new quartz mining district, although its placer mines have been worked successfully for years past.

SONOMA.

LOCAL ITEMS.—Russian River Flag, June 17: W. R. Mathews and Mr. Bryant of the Excelsior company (Inyo district) came up from San Francisco last week, and have succeeded in settling satisfactorily with the creditors of the company in this region. Work will soon be resumed on the mine, and also on the Alhambra.

The Sussal company mean business. Work was resumed this week. Under the influence of the assessment it will be vigorously pushed till the ledge is reached. The tunnel is now in a depth of about 120 ft, having reached a point directly below the extensive croppings. The tunnel may not reach the ledge for 60 or 70 ft, however, as it is not known how great the dip is.

Nevada.

WASHOE DISTRICT.

CALIFORNIA.—Gold Hill News, June 17: The cross-cuts are being gradually extended at all points on the 1500-ft level, and lateral drifts are being run to connect the cross-cuts, so as to afford the most complete ventilation of the mine in every quarter by the time the new mill is completed, ready for the reduction of ore. On the 1400-ft level the same system of cross drifts and prospecting is being carried out, which, in connection with the various winzes already sunk and now being prosecuted at various points will make it one of the best ventilated mines on the Comstock, by the time everything is in readiness to commence the extraction of its rich ores. Sinking the C. & C. shaft is making good progress. It is now down 550 ft. A strong force of stone masons are employed on the foundations for the machinery, which are being pressed to completion with all the vigor possible. The erection of the new mill is also making rapid headway.

BELCHER.—Daily yield, 400 tons of ore. There is no change of interest or value in the character of the ore extracted, or the general appearance of the ore producing sections of the mine. The main north drift on the 1500-ft level is being rapidly driven ahead to connect with the south drift on the same level from the Crown Point, for ventilation purposes. Preparations are also being made for the commencement of ore stopping on the 1500-ft level. The main incline is down 50 ft below the 1600-ft level, the bottom in good working ground. The 1600-ft station is being opened, preparatory to commencing the development of that level. The air shaft is completed down to the 1200-ft level. The mills are all kept steadily running on ore from the mine, and everything in and about the mine is in fine working condition.

LADY BRYAN.—The south drift on the 380-ft level is being steadily advanced, following the east wall of the ledge. The west cross-cut on this level has penetrated the ledge a distance of 85 ft, the entire distance through quartz of the finest possible character, and containing some fine streaks and bunches of ore. The west cross-cut on the 80-ft level has penetrated during the week several ft of fine ore, and the appearances are excellent for finding a valuable body of pay ore at that point.

THOMPSON CONSOLIDATED.—Shaft 250 ft deep, and making good progress downward. The last 25 ft has been in very promising ledge matter, 7 ft of which, including the bottom of the shaft, is in vein material which gives assays from \$14 to over \$400 to the ton. This may develop or concentrate into a nice little bonanza of itself, but the regular main ledge of the mine lies to the westward, and the shaft is to be sunk to the depth of 500 ft before drifting for it.

UNKNOWN POINT.—Daily yield between 550 and 600 tons of ore. The ore breasts continue their usual yield, without any signs whatever of exhaustion, the indications if anything tending to show an improvement in the quality of the ore extracted, the yield for the past month being over \$50,000 above the cost of extraction and milling. The increased prospects of the ore vein on the 1600-ft level is also giving strong hopes of a paying body of ore when the ledge is reached on the 1700-ft level. The

mills are all kept steadily running up to their full working capacity, and the general outlook of the mine is certainly more prosperous than for some time past.

CONSOLIDATED VIRGINIA.—Daily yield, 600 tons of ore. The ore breasts throughout the mine are all looking well, and show no abatement in either the quantity or quality of ore extracted. No work is yet being done on the 1550-ft level, with the exception of the raising up of a winze 12 ft square for air purposes. This winze is passing through fine ore and is rapidly approaching completion. The prospecting of the upper levels of the mine is very nearly completed, so that but little now remains to be done except to extract and mill the ore. The mills are all kept running up to their full working capacity, and the yield of bullion will not vary much from \$1,500,000.

CALIFORNIA.—Sinking the main incline is making steady progress, the bottom is good working ground. Sinking the new shaft is considerably impeded by the steady, strong flow of water at the bottom. Preparations for the erection of the new and powerful hoisting machinery are being pushed ahead with all the vigor possible.

GOULD & CURRY.—The erection of the new and powerful hoisting engine is completed. This, taken in connection with the new and powerful pumping machinery recently started up, places everything in and about the mine in the finest possible working condition.

OPHRE.—Daily yield, 150 tons of ore. The ore breasts and stopes on the 1465-ft level show no change of value during the week. Driving the east cross-cut on the 1700-ft level is making steady headway, with some more favorable indications of reaching the ore vein at no distant day. The heavy dressed stone blocks for the reception of the new and powerful incline machinery, are in place ready for its reception.

SIERRA NEVADA.—Sinking the new shaft is making steady and favorable progress, the rock in the bottom blowing out finely and there being no water whatever to interfere. The erection of the new and powerful air compressors is very nearly completed.

BALTIMORE AND ANGELOAN FLAT.—The prospects of a favorable ore development in the south drift on the fourth station level is growing better every day. The body of ore recently struck by the cross-cut from the bottom of the winze below the third station level, is of a fine quality, and is gradually widening out.

CHOLLAS-POTOSI.—Sinking the main incline is progressing at the rate of two feet per day. The main south drift, on both the 1150 and 1250-ft levels, are being steadily driven forward, the face of both in porphyry. Daily yield, 70 tons of ore, of the assay value of \$29 per ton.

FLORIDA.—Struck the east clay well at the 400-ft level in the face of the main drift west, which is now going into it and the on skirts of the ledge about 7 ft. Indications very promising. The new machinery is in working position and operates splendidly.

DAYTON.—The dressed stone blocks for the reception of the machinery are all in place. The frame of the new hoisting works building, 46x100 ft in size, is finished, and the erection of the machinery can now be rapidly pushed to completion.

AMAZON.—The shaft is down 209 ft vertically, at which point a cross drift has been run 60 ft, at the end of which the ore vein was struck, developing a fine prospect of good ore. This body of ore has been penetrated a distance of 10 ft, the face of the drift still in ore.

LEO.—Excellent progress is being made in sinking the winze, which is to-day down 118 ft, following the pitch of the vein below the main tunnel level.

PHIL. SREIDAN.—The face of the drift is evidently in the outskirts or immediate vicinity of the main ledge, judging from the material now being passed through, which is soft porphyry, clay and quartz, from which assays of \$20 and over are being obtained.

JULIA.—Sinking the main shaft is making good progress, the rock in the bottom being much softer. The work of putting in another lift pump at the 1200-ft station is rapidly approaching completion.

WOOLVILLE CONS.—Sinking the main shaft is making steady progress. A considerable body of quartz with streaks of rich ore has been encountered during the week, without yet reaching the west wall of the ledge.

NEW YORK CONS.—The grading for the new and powerful hoisting and pumping machinery is about complete, and the mason work for the foundations will be commenced next Monday.

SOUTH CALIFORNIA.—The sinking of the shaft progresses at a very good rate, the rock at the bottom blasting well. The new hoisting works machinery contracted for will soon be on the ground.

SEG. GOLD HILL.—Another good body of ore, better than the first, has been run into, in drifting at the 400-ft level. It assays over \$50 to the ton, and is an important development.

SUCCEA.—The face of the west drift on the 550-ft level is still in porphyry. The ore in the face of the north drift from the old shaft continues to show an improvement.

JACOB LITTLE CONS.—The ore body developed by the west drift is opening out splendidly, with well defined wall and continued improvement in the character of the ore.

ORIGINAL GOLD HILL.—The southern cross-cut from the main south drift is now in excellent ore, which is opening out finely. North drift going ahead as usual.

Railway Progress.

Notwithstanding the fact that the continent of Europe is now well covered with lines of railroads; that 8,000 miles of railroads have been constructed in England within the last fifteen years; that France and Italy have pierced Mont Cenis to effect a closer and more direct railway union; that Austria is carrying new lines across the plains of Hungary, while Russia is occupied with extensive schemes for connecting St. Petersburg and Moscow with her Black Sea ports on the one hand and with the frontier towns of her Asiatic empire on the other—notwithstanding all this great end rapid progress in Europe, the railroad mileage of the United States, with a population of 40,000,000, fully equals that of Europe with a population of 282,000,000.

In British India about 5,000 miles of railroad have been laid down within the last sixteen years, while great achievements have been performed in the British provinces on this continent.

Official reports show that no less than 70,651 miles of railway were in use in the United States at the end of 1873. The degree to which large cities are now dependent upon railroads for the supply of food is exhibited by some startling statistics recently published in London, from which it seems that great city is fed by railroads from day to day, having never more than a few days' supply of provisions on hand at any time. A railroad strike in that city would starve the population into submission in a week. All that an invading army would have to do to completely reduce the largest city in the world would be to cut off her railroad communication for a few days. Were the full statistics of a similar character collected for our American cities, the result would no doubt be almost equally astonishing.

Great efforts are now being made to avoid the accidents which have been so alarmingly frequent during the past. Improved rails, switches, couplings, danger signals, brakes, etc., are now being introduced, the beneficial effects of which are already beginning to be felt. The introduction of the steel rail is of much greater importance than was that of the T-rail in avoiding the "snake-heads" of the old fashioned flat rail. By these and similar improvements two important objects are gained—an increase of speed and decrease of danger.

The Pennsylvania road between New York and Pittsburgh—444 miles—has recently laid down 60-pound steel rails, with improved ties, ballast, joints, etc. By the aid of these improvements, with heavy and improved locomotives, the distance is now made in eleven hours, including stops—an average of over 40 miles an hour, or double the speed of our California roads. The locomotives on this road dip up their water as they run, and there is probably no railway in the world of equal length whose passengers are carried more expeditiously, speedily or luxuriously.

Steel Rails for California.

It is gratifying in this connection to be able to state that California is also making progress in the way of railway improvement. The Southern Pacific railroad company of this State has recently contracted with the Pennsylvania steel company and the Bethlehem iron company for 10,000 tons of steel rails—5,000 from each company—to be used in continuing the line of the road south of Los Angeles in the direction of Fort Yuma, the southern terminus of the road, at the junction of the Colorado and Gila rivers. The distance by rail from San Francisco to Fort Yuma is 722 miles. At Fort Yuma the Southern Pacific will probably connect with the Texas Pacific (Col. Scott's road), and farther north, at Fort Mohave, on the Colorado river, another eastern connection is expected to be made in time. The steel rails ordered are to weigh fifty pounds to the yard, and the quantity ordered will lay 100 miles of single track, including sidings. The rails will be shipped by sailing vessels around Cape Horn.

We hope that this transaction may be but the beginning of a large trade in steel rails and iron and steel products generally between the East and the Pacific coast. The States and Territories of the Pacific slope consume annually about 300,000 tons of iron in all forms, and until they are ready to make their iron and steel it would certainly be wise for them to buy their supplies from sister States rather than from foreigners.

LEATHERETTE.—This new patent imitation of leather, which has already been fully described, is alluded to in a late number of the *British Trade Journal*, as follows:

Specimens of leatherette, a capital imitation of leather, have been submitted to us during the past month, and make evident that some improvements have been effected in the manufacture which seem to justify further notice.

Briefly then, this leatherette is now dyed throughout, the surface—representing with wonderful fidelity the natural grain of leather—is more defined, and while the fabric has been strengthened, greater softness and a more leather-like feeling have been imparted to it. It is thus admirably fitted for use by bookbinders, and in many trades which have recourse to what we may term fancy leather.

Tin—Its Manufacture and Supply.

Tin plate or sheet tin forms one of the most important branches of England's domestic industry, supplying the world with this indispensable material; for millions of boxes, containing 112 pounds each, are exported annually from there, and a million boxes are yearly imported into the United States. The tin plate consists of sheet iron, alloyed and coated externally with pure tin. Sheet iron of the best quality is cut into sizes required, bent into a triangular form, heated to redness in a reverberatory furnace, dipped into hydrochloric acid, drained, and again heated to scale the whole surface. This forms the most important

(Fig. 1)

SNYDER'S LADIES' WORK TABLE, IN USE.

operation, for any trace of oxide would prevent the adhesion of the tin. They are then beaten level and smooth, passed cold through chilled rollers, immersed in lye, a weak bath of fermenting brine water, pickled by agitation for some time in a bath of diluted sulphuric acid, scoured in water with sand and hemp, and kept for use in pure water. The clean plates, dried by bran, are kept in a bath of melted tallow, called a grease pot, for an hour, and then passed through a series of rectangular pots. The first is the tin pot, containing the

for the past fifty years been closely watching this metal. But however attentively it may have been followed by men of note in mercantile knowledge, the basis of production has undergone such radical changes that all calculation has been set at naught, and the persons who took cognate from statistical arguments and confidently held tin, have quite recently experienced heavier losses on this metal than any other, if we except quicksilver, which declined fifty per cent. within the past few months.

Tin has proved all the more treacherous, both to the consumptive and speculative holder, as its use in reality has rapidly increased; but as production has also been excessive, the downward course of the article has remained unchecked, except during short periods of temporary recovery.

The English mines are becoming more and more unprofitable, yet they are struggling on.

A year's stoppage in Cornwall would relieve tin production of a surplus supply of 10,000 tons. The Banca production ranges annually between 3,000 and 4,500 tons.

The Malacca supply ranges between 7,000 and 10,000 tons.

The Australian production has been rapidly on the increase. The yield of 1874 was 5,800 tons, against 2,990 in 1873.

From latest accounts the demand in Europe continues good, and the deliveries are large, but the arrivals still keep pace with them.

Fig. 2

SNYDER'S LADIES' WORK TABLE, CLOSED.

melted block tin, covered with grease, into which the plates are dipped one by one, and kept there one hour and a half; then they are put on an iron grating to drain, and dipped into a wash pot containing the fused tin. Into this the superfluous tin is removed from the surface. The plate is then lifted out, scoured on both sides with a hempen brush, dipped for a moment into the melted tin in a compartment of the wash pot to remove the marks of the brush and give uniform smoothness to the surface, and then immersed in the adjoining grease pot, where some superfluous tin is removed, and collects on the lower edge. The plate is next put into an empty pot to drain. When cool enough, the lower edge of the plate is dipped into the hot pot containing melted tin one-quarter of an inch in depth, by which the accumulation of tin on the edge is melted off, leaving a dull edge, which may be seen on all the sheets. The plates are then cleaned with bran and pecked. About eight pounds of tin is required to cover 225 plates, which weigh 112 pounds.

Few articles of merchandise have attracted as much attention during the past few years as tin. No one of the metals is so extensively dealt in by merchants and bankers at large; hence the best statisticians of Europe and America, not only in the metal trade, but in the great articles of merchandise in general, have

Upon examination of the general statistics of tin, it will be found that the supply has been considerably increased, but while this has been the case, consumption has, in spite of the dull times on the other side, been on a larger scale than was ever before known. If the general metal trade had been in full swing in Europe, consumption would probably have been sufficiently large to keep the aggregate visible supply at the same figure at which it stood January 1st.

The immediate future of tin values will therefore mainly depend on the whole course which the metal trade will take in Europe during the next few months. Speculators for a rise seem to find it too difficult to grapple with the problem of tin values with any degree of solid success; for the moment a rise of five per cent. is established, steam via the Isthmus of Suez bestens the arrival of fresh supplies, and the advance as rapidly vanishes.

The American consumption of pig tin is so small at present that little can be expected in the way of a favorable diversion on this side during the summer months, while toward fall greater briskness is likely to prevail, and may coincide with some speculative movement.

Iron filings in a weak solution of sal ammoniac, mixed with Portland cement, are said to double the strength of the latter.

Explosives.

At the last meeting of the chemical section of the Society of Arts, in England, for the present session, a day or two ago, a paper by Mr. Alfred Nobel, of Paris, on the subject of "Explosives" was read, in the absence of the author, by Mr. T. Wills. The paper commenced with a retrospective view of the history of explosives invented from time to time to replace gunpowder in blasting operations. Connected with the use of ordinary gunpowder were many advantages which rendered it a matter of difficulty altogether to supersede it; yet it had certain defects, in view of pelleting which a long series of explosive materials had been introduced, most of them having met with but indifferent success, owing chiefly to the slowness of their action. A novel class of explosives had been lately invented by Dr. Herman Spring, which, if not likely at once to be brought into practical use, presented, in a scientific sense, a peculiar and startling interest. The first practical substitute for gunpowder had been gun cotton, introduced by Schoenbein, in 1846. The idea of employing this powerful substance had at one time been almost abandoned, until the researches of certain chemists—notably those of Professor Abel—had revealed an easy means of rendering its use perfectly safe. The most formidable rival which gun cotton had yet encountered was unquestionably nitro-glycerine, invented by Sobrero, almost simultaneously with the production of the former material. Though nitro-glycerine had met with much opposition, on account of the dangers said to attend its use. These dangers had been much overestimated. The embodiment of nitro-glycerine in the solid form of dynamite had, however, after a long struggle with public prejudice, led to its very extensive employment as a blasting agent. A short description of subsequently discovered substances of a kindred nature here followed, with a comparative statement of their relative mechanical explosive powers, ascertained by means of scientifically conducted experiments. From these it would appear that the highest places on the list of practically employed explosives is filled by nitro-glycerine. The application of detonation to the discharge of blasting materials was then brought under consideration, and some full observations on the various sources of danger liable to occur during the manufacture, transit, storage, and use of nitro-glycerine and other explosives occupied the remainder of the paper.

Ladies' Work Table.

The accompanying illustrations represent a new ladies' work table, patented by C. E. Snyder, of Minneapolis, Minn. The lid of the table, as shown in Fig. 1, is readily convertible into a lap board by the side arms turning on a pivot, and resting, when down, on pins in the table legs. The legs of the lap board serve as supports for the table lid when up, and are then folded under, out of sight, as indicated in Fig. 2. If desired, the clep board can be detached from the table and used independently, in which case the elongated side arms become legs. The conformity of the table to the shape of the lap board gives a beautiful design for the former, and at the same time admits of a very convenient arrangement.

The recess in front is used for a double row of spools, retained in place by brass standards. The center piece forms a pin cushion. This recess may be tastefully ornamented. The divisions over the right hand drawer may be used for writing utensils, those over the left drawer for "notions," while the division between will hold a large quantity of out end baited work. The inventor may be addressed, as above, by those who desire to manufacture these tables.

Cost of Reduction.

We give to our miners, says the *White Pine News*, the rates charged at Eureka for the reduction of ores, which will aid some of our mine owners in estimating what kind of ores will pay for shipment and reduction. It would seem from the rates charged that nothing less than one hundred dollar ore would pay for shipment, which is comment enough to induce capitalists to build furnaces here, owing to the fact that there is a large amount of ore already taken out which will pay from sixty-five to seventy dollars per ton. There is still another fact which should be remembered by those visiting this camp with a view of investing, which is, that contracts will be made to furnish any amount of ore that will pay the above named sums per ton.

The following rates, free of smelting charges, will be paid for gold and silver bearing ores at the Eureka Atlas smelting works:

Ores assaying 60 dollars per ton, 16 per cent. of value.	
Ores assaying 60 dollars per ton, 25 per cent. of value.	
Ores assaying 70 dollars per ton, 35 per cent. of value.	
Ores assaying 80 dollars per ton, 45 per cent. of value.	
Ores assaying 90 dollars per ton, 46 per cent. of value.	
Ores assaying 100 dollars per ton, 50 per cent. of value.	
Ores assaying 150 dollars per ton, 55 per cent. of value.	
Ores assaying 200 dollars per ton, 60 per cent. of value.	
Ores assaying 225 dollars per ton, 60 per cent. of value.	
Ores assaying 250 dollars per ton, 62 per cent. of value.	
Ores assaying 300 dollars per ton, 63 per cent. of value.	

For higher grade ores, rates by special agreement. Lead, over 20 per cent. will be paid for at the rate of 40 cents a unit, until further notice.

Good Health.

A New Medicinal Plant.

A Brazilian plant bearing the savage name of "Jaborandi" appears to be the coming drug. It was first introduced into Europe about one year ago, but has grown rapidly in estimation with the medical fraternity since that time, so much so that the English wholesale drug houses are ordering immense quantities of it from Pernambuco, near which port it abounds. It is a shrub which grows about five feet high, with a cylindrical, tapering root, very springily branched, the bark of a pale yellowish color and very brittle.

Experiments with this drug suggest a curious relation, partly of analogy but mainly of opposition, between jaborandi and belladonna. It resembles atropia in quickening the pulse, flushing the face, and exerting a more decided influence on adults than on children. On the other hand, it is diametrically opposed to atropia in its actions on the salivary, sudoral, and mammary secretions, on the pupil, and on the minute arteries. Further, the tendency of belladonna to cause delirium contrasts with that of jaborandi to cause prostration and apoplexy. It has been proved that atropia is able to arrest the flow of saliva caused by jaborandi; and Ringer found that a dose of the latter drug speedily removed the dryness of the month in a case of accidental poisoning by atropia. Sweating after jaborandi may be prevented or checked by the subcutaneous injection of one-hundredth of a grain of atropia.

As a sudorific the drug is likely to prove of great value. It may also turn out to be a trustworthy antidote in poisoning by belladonna; and other virtues, unsuspected as yet, may be found to exist in the plant when it becomes better known. Hence pharmaceutical, medicinal, and chemical investigators are turning their attention to jaborandi. Dr. Ringer and some of his associates at the London University College hospital have been experimenting with this medicine therapeutically. To adults they have administered doses of from sixty to ninety grains in the form of infusion, and in nearly all cases profuse perspiration and most enormous salivation ensued very rapidly. The saliva collected from the patients averaged about an Imperial pint, and in one instance amounted to twenty-seven fluid ounces. Evidently the medicine is possessed of very important properties, and it now becomes a question of considerable interest to ascertain the precise principle of the plant to which these effects are due. Several chemists are working at the subject, and this doubt will therefore probably be soon cleared up.

Don't Eat Mathematically.

Persons in good health should not eat any article of food simply because it is "healthy," nor avoid any article because some one says it is "unhealthy;" nature's instincts are a better and safer guide, for she craves food, the distinctive elements of which are needed in the system; hence no man likes or dislikes of an article of diet should be the guide of another, any more than all soils should require the same fertilizer, in quality and quantity.

Sometimes, indeed—but rarely in good health—a man may crave earnestly an article of food, and after eating it feel uncomfortable; yet, rather than conclude it did not agree with him, and discard it, a smaller quantity should be taken next time, and very often that smaller quantity, well divided, prepared properly and eaten slowly will "agree" simply because the system needed only that smaller quantity.

Brown bread is said to be good for many persons by its keeping the system open and free; but if a man is well enough in that respect, he would do well not to eat brown bread, unless he was fond of it, so as to have it to fall back upon, should he need its medicinal effect. In short, eat according to the natural appetite as to quantity and quality, and not according to artificial rules and regulations.

If a man is an invalid and has a family physician, it is safer and better to put himself under that physician's guidance; if he has no physician, let him feel his own way, taking small quantities at regular intervals, and closely observe the effects. But for both sick and well, it is just as unwise to measure and weigh each meal day after day, as it would be to wear the same amount of clothing and consume the same amount of fuel every day in the year, winter and summer. In mature life we eat for two reasons, to repair waste and to keep the body warm; the waste is in proportion to the preceding exercise, and the internal warmth needed is in proportion to the temperature of the atmosphere about the body. If you eat to-day while idle, and the thermometer is at sixty, as much as you did yesterday, when it was at zero, and you worked hard, you will certainly be sick to-morrow. After all, don't make a god of your belly, but accustom yourself to think of eating and what you shall eat, only when the time for eating comes; a beast or a glutton may do otherwise, a man will not. —Hall's Journal.

THE EAR.—Mr. James Hinton, in his "Physiology," affirms that the passage of the ear does not require cleaning by us. Nature undertakes that task, and in this healthy state fulfills it perfectly. Her means for cleansing the ear is the wax, which drips up into thin scales, and peels off and falls away imperceptibly. In health the passage of the ear is never dirty, but an attempt to clean it will infallibly make it so. Washing the ear out with soap and water is bad; it keeps the wax moist when it ought to become dry and scaly, and makes it absorb dust. But the most hurtful thing is the introduction of the corner of a towel screwed up and twisted around. This proceeding irritates the passages and presses down the wax and flakes of skin upon the membrane of the tympanum, producing pain and inflammation and deafness. Washing should only extend to the outer surface, as far as the finger can reach.

THE EFFECT OF EMOTION.—It is related by Sprengel in his "Geschichte der Arzneikunde," that the Arabian physicians sometimes relied with great success on moral means, of which the following is a striking instance: One of Haroun Al-Raschid's wives suffered from paralysis of both arms. Dschibrail, the court physician, induced the caliph to summon all the leading nobles to a large hall in his palace, and then introduced the lady to the assembled multitude. Without a word of preface he raised her veil, when feelings of shame and fear restored strength to the palsied arms. The lady hastily drew her veil down again, and was cured from that hour.

THE EFFECT OF BUCKWHEAT ON THE BLOOD.—Does it drive the impurity of the blood to the outside, or does it make the blood more impure and, by reason of excess, causes impurities to come to the surface? Ans.—The harm is not due to any injurious ingredient in the buckwheat. It is to be ascribed to the large amount of butter and fatty matters eaten at the same time.

USEFUL INFORMATION.

Black Walnut Finishing.

The fashionable finish for black walnut work, particularly chamber sets, is what is known to the trade as the "dead oil finish." It is admired, perhaps, because it has a gloss, rather than a shine of the varnish stamp. There is no more labor required upon it than upon a bright finish, but the process of manipulation is different, and harder upon the fingers.

It should be premised that the walnut work of the day bears upon its surface, to a greater or less extent, raised panels covered with French burr veneer. And upon this fact depends the beauty of the production to a very great extent. And the effort is, to so finish the article that there shall be a contrast between the panel and the ground work on which it is placed. In other words, the former should be of a light color, while the latter is of a darker shade. In that view the palest shellac should be used on the panels and darker pieces, liver colored, etc., on the body of the work. The darker grades of shellac are the cheaper and will answer for the bulk of the work, but the clearest only for the panels.

In commencing to finish a job direct from the cabinet maker's hand, rough, and innocent of any knowledge of sandpaper, the panel should first be covered with a coat of shellac to prevent the oil in the filling from coloring them dark. Next, cover the body of the work with a wood filling composed of whiting and plaster of paris, mixed up with japan, benzine and raw linseed oil, or the lubricating oil made from petroleum; the whole colored withumber, to which, in rare cases, if a reddish shade is wanted, venetian red is also added. This filling is then rubbed off with cloths, and by this process tends to close up the grain of the wood and produce an even surface. More or less time should be allowed after each of the several steps in the finishing process for the work to dry and harden, though much less is required in working with shellac than with varnishes composed of turpentine, oil and gums. But the time allowed is often hurried by the desire to get the work through as soon as possible, so that no standard can be set up as to the number of hours required between each of the several processes. It would be well if twelve hours intervened, but if the work must be hurried through in three days, which can well be devoted to, obviously, the processes must follow each other in a corresponding haste.

A coating of shellac is then given the whole work, light on the panels and dark on the body work, and when it has dried and hardened, which it does very soon, it may be rubbed down. This process of "rubbing down" should be done evenly and carefully, so as not to rub through the shellac at any point, and is done with the finer grades of sandpaper for the cheaper class of work, particularly at first, but at a later period of the process, and for the better class of articles in all cases, hair cloth should be used; the material for the "rubbing down" should be pumice stone moistened with raw linseed oil for the best work, and the lubricating oil, before mentioned, for cheaper work or the covered parts of the better grades. This rubbing down involves labor, wear of

fingers and finger nails, and is carried on with an ordinary bit of hair cloth, the smooth surface next the wood, and not made in any particular shape, such as a wad, or ball, or otherwise. In the corners and crevices where the hair cloth will not enter it will be necessary to sandpaper; the finest grades, and worn pieces only.

Three coats of shellac are put on, followed each time by this "rubbing down" process, each one giving the work a smoother feeling and a more perfect appearance. Afterward, to complete the whole, a coating of japan, thinned with benzine, is applied, which gives a clean appearance to the work, and the dead glossy finish.

There is this objection to the above style of finish, that the japan catches all the dust which touches it and holds it permanently, so that many of the best workmen will not have work finished in this way for their own private houses, preferring the brighter look made by shellac and varnish without rubbing down the last coat, and saying that the work can be kept much cleaner.

The large oval panels of desks, etc., covered with French veneer, are generally taken out and finished by themselves. The process is similar to that above given, excessive coats of shellac, and varnish also, with the oil and pumice stone "rubbing down"; but the final part of this latter process is a "rubbing down" with rotten stone; then a very trifling of sweet oil is applied all over the surface and wiped off. —Cabinet Maker.

Glazing of Pottery Without Lead.

A mixture of feldspar, silica, kaolin and fluor-spar may be used to glaze bricks and pottery in a manner as perfect as the common lead glazing, and much more safe in a sanitary point of view. When the ingredients are once mixed, they are ground in cylinders to a powder, which is passed through a very fine sieve. This powder, of which the natural color is white, but to which all the tints can be given, is mixed with water in a tub, till it presents nearly the consistency of molding plaster.

The brick, or piece of pottery which is to be glazed, is then plunged into this mixture. It adheres, on account of the porosity of the material, with which it incorporates while drying. Being placed in earthen forms, they are exposed in ovens to 1,500° Fahrenheit. The heat melts the preparation, and the glazing spreads uniformly over the surface of the objects, which only have to be taken out of the oven to cool.

Bricks treated in this way have great advantages. They are of an unusual strength, and resist as well the influence of the atmosphere as the action of the acids. They can successfully be employed to cover walls on the inside or outside, which they preserve completely from dampness. This method of glazing may be made available for many industrial applications.

REPAIRING RUBBERS.—Rubber, or even leather boots, may be repaired by using the following cement: Take gum shellac three parts, india rubber one part, by weight. Dissolve these ingredients in separate vessels, in ether free from alcohol, applying a gentle heat. When thoroughly dissolved, mix the two solutions, and keep in a bottle tightly stoppered. This glue resists the action of water, both hot and cold, and most of the acids and alkalis. Pieces of wood, leather, or other substances, joined together by it, will part at any other point than at the joint thus made. If the glue be thinned by the admixture of ether, and applied as a varnish to leather, it renders the joint of seam water tight, and almost impossible to separate. By cementing a piece of thin leather or rubber over a crack, a neat and durable patch may be made. The soles of leather boots may be made more durable and perfectly waterproof by soaking them thoroughly, before a fire, with common pine tar. Three or four repeated applications are necessary to saturate the leather, when it completely absorbs the tar, and the soles are dry and hard as horn, but quite flexible.

COPYING MANUSCRIPT.—The following is a simple way of obtaining copies of writing without the use of a copying press: Mix white sugar with the ink; one and a half drams sugar to one ounce ink. Use this with an ordinary pen, and place over the writing a moistened sheet of unsized paper. Lay both leaves between two layers of carpet; put the whole under a piece of board large enough to cover. Then stand on the board for a few seconds. An excellent impression will be found on the copying paper.

TO FIT A KEY.—When it is not convenient to take a lock apart to fit a new key, the key blank should be smoked over a candle, inserted in the keyhole, and pressed firmly against the opposing wards of the lock. The indentations in the smoked portion made by the wards will show where to file.

The best pine wood evaporates five pounds of water per pound of wood consumed in a steam boiler furnace. One cord of wood can be consumed per hour on sixty square feet of grate. One pound carbon burnt to carbonic acid requires the oxygen of 153 cubic feet of atmospheric air.

GLYCERINE added to paper stock increases the flexibility of the paper.

DOMESTIC ECONOMY.

Summer Salad.

At our leading hotels and restaurants, indosed on the tables of the distinguished, it is very rare, says the Germantown Telegraph, to find lettuce, as a salad, worthy of the name. Green and bitter, by the aid of mustard, eggs, oil, or occasionally a scald, it is rendered just passable, but as unlike what cool delicious salad ought to be as is possible. It seems practically to be forgotten by those who grow salad that lettuce was never intended to be eaten unless blanched. In Europe they grow a long broad-leaved kind, called the Roman or Cos lettuce, which, after having attained considerable development, has the leaves drawn up and tied together at the top. The interior continuing to grow, and of course in the dark, by the tying up of the outer leaves, makes a hard mass like an elongated cabbage, which cuts up as white and crisp and sweet as a stick of celery. This kind has never found a place in American gardens, because our climate induces it to run to seed too quickly. The various kinds of cabbage lettuce are preferred, because they close in their leaves naturally, and are supposed to blanch themselves. But this is, as we have shown, a pleasant fiction, as there is very little of the white about any that we see, except where there is great care in the culture.

Of course our country is not so well adapted to the growth of good lettuce as England is. It will not stand extreme cold, nor does it like warm days and hot suns. It wants to go to seed as soon as the temperature goes over sixty-five degrees. But we could have much better than we do. In this spring we sometimes get a tolerable article. Started by a little protection from frames, it is brought to perfection before the warm weather comes. To have it good later is not difficult, by employing very rich land and as cool a spot as can be obtained. All vegetables that we value for their succulence require a rich soil to their best development, but it is an essential to good summer lettuce.

Of course varieties will assist. Some of American origin have been found to stand our heats without running to seed much better than the English varieties, which are better suited to that cooler summer climate. Of these the Indian lettuces are examples. Some of these have been improved, and of these the Hanson bears a good reputation.

COOKING RHUBARB.—Rhubarb is best cut in lengths, boiled in water and sugar and served with boiled rice round the dish; or, it may be treated like "gooseberry fool." A little good cream gives it a delicate taste, which it never has in a pudding or tart. The following are excellent recipes for making rhubarb jam and marmalade: Cut the rhubarb as if for tarts, and to every quart give one pound of good moist sugar; put the sugar over the rhubarb and leave it twenty-four hours to draw out the juice. By this method the pieces of rhubarb remain separate from each other when the preserve is done. It keeps good a year if kept in jars well dried, and in a dry place. For the marmalade procure six oranges, peel them and take away the white rind and pips, then elice the pulp into a stewpan along with the peel; cut very small; add thereto one quart of rhubarb cut finely, and from one pound to one pound and a half of sugar. Boil the whole down in the usual way as for other preserves. Made in this manner it is nearly equal to Scotch marmalade, which is regarded on all hands to be the finest anywhere made.

DRINK MILK AND GROW FAT.—Livingstone found that in Africa the use of sour milk promoted the growth of the muscle and fatty matters, and it also appeared to be a preventive of biliousness, while sweet milk had the opposite effect. It is stated that a pinch of salt in sweet milk will prevent any disordered stomach, drowsiness or other ailment, and that if any one wishes to grow fleshy, a pint, slightly salted, taken before retiring at night, will soon cover the scrawniest bones. In cases of fever and summer complaint milk is now given with excellent results. The idea that milk is "feverish" has exploded, and it is now the physician's great reliance in bringing through typhoid patients, or those in too low estate to be nourished by solid food.

SARATOGA POTATOES.—The following is said to be all there is of the cook's secret in producing those world-renowned potatoes served at Moon's Lake House, Saratoga Springs, every summer: Peel good sized potatoes, and slice them as evenly as possible; drop them into ice water. Have a kettle of lard, as for fried cakes, and very hot. Put a few at a time into a towel, shake them about to dry them, and then drop into the hot lard. Stir them occasionally; and when of a light brown take them out with a skimmer. If properly done, they will not be at all greasy, but crisp without, and meaty within.

ASPARAGUS AND BEANS.—Cut the tender parts of the asparagus into quarter inch lengths, boil in an equal quantity of water, adding about an equal amount of well cooked Lima beans. Cook until the asparagus is tender, and serve warm. Instead of the beans the asparagus may be thickened with flour or with cracker crumbs.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—A New Gear-Cutting Machine, 403; Shincing, 409; Fryer's Process, 416; Onsevera, 418; Removing Broken Drills from Holes, 416; Work at the Foundries, 416; Nanaimo Coal, 416; Notices of Recent Patents, 416; Short Lectures on Patents, 428.

ILLUSTRATIONS.—Peer's Gear-Cutting Machine; Shincing in a Rain Storm, 409. Lane & Bodley's Improved Saw-Mill, 417.

CORRESPONDENCE.—Australian Notes, 410.

SCIENTIFIC PROGRESS.—On Some Recent Observations on Magnetism; The New Glass—Another Process of Producing It; Curious Experiment in Instantaneous Crystallization; A New Artificial Light for Photographing; A Novelty in Ornamental Silvering, 411.

MECHANICAL PROGRESS.—The Cold Steam Motor; Pottery in the United States; The Sand Blast—New Applications; A New Carriage Wheel for the Road; A Great Improvement in Nail Machinery; New Barrel Machine; Bending vs. Forging; Rapid Work; Stamping Mold Boards, 411.

MINING SUMMARY from the various counties in California and Nevada, 412-13.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 413.

USEFUL INFORMATION.—Black Walnut Finishing; Glazing of Pottery Without Lead; Repairing Rubbers; Copying Manuscript; To Fit a Key, 415.

GOOD HEALTH.—A New Medicinal Plant; Don't Eat Mathematically; The Ear; The Effect of Emotion; The Effect of Buckwheat on the Blood, 415.

DOMESTIC ECONOMY.—Summer Salad; Cooking Rhubarb; Drink Milk and Grow Fat; Saratoga Potatoes; Asparagus and Beans, 415.

MISCELLANEOUS.—Coal Fields of Puget Sound; Mariposa Estate; Mining Strike; Preservation of Eggs, 410. Railway Progress; Leatherette; Tin; Its Manufacture and Supply; Explosives; Cost of Reduction, 414. Revised Statutes of the United States, Relating to Mineral Lands and Mining Resources, 417-18-19. Lead, 421-22. The Manufacture of Solder; Greatest Power of a Horse; To Gild with Gold, 422.

Miners, Help Your Paper!

Write for it. Subscribe for it. Speak of its merits. Influence others to subscribe for it. Are we not doing an important work for the prosperity of our mining districts? Are we not adding, by our steady work, millions of dollars to the product of our mines? Are we not disseminating that intelligence to miners, mechanics, and mine operators which prevents the ignorant squandering of millions of dollars? Are we not storing the minds of active professional men, and thousands of intelligent sons of toil, with more refined and lasting treasures than silver or fine gold?

The publication of scientific journals is not proverbially profitable in any part of the world. They are more costly than ordinary journals. Engravings are expensive—especially so in a new country. We have striven to make a valuable journal, an enterprising sheet, a reliable issue. We need the hearty support of the classes the MINING AND SCIENTIFIC PRESS especially represents; we ask it now. We thank old subscribers for their patronage; we solicit all to promptly renew.

ONE of Baker's Rotary Blowers (advertised in another column) has been running for five months at McCormick, Lewis & Co.'s Industrial Iron Works, 233 Beale street, in this city, where it can be seen and examined.

CONNECTION by rail with San Bernardino will soon be completed. Twenty miles have just been finished, out from Spadra.

Fryer's Process.

We see by the Grass Valley papers that Mr. Fryer, the inventor of the much talked of new process for working gold bearing quartz, has arrived in Grass Valley from the East. He will soon commence work on a large scale. He is sure that his process is a perfect success and that he can work ore to within 95 per cent. of its assay value, and at a cost not exceeding \$5 per ton. Base metals, of any kind, in the ores do not prevent successful working. The Union says the process has been tried without costing anybody anything, excepting Mr. Fryer and his associates. These gentlemen will also run the extended operations on the same principle, hearing all the expenses thereof and allowing no one on the outside to lose anything if a failure should occur.

In view of the fact that the new process will cause ledges to be worked more profitably than heretofore, the miners in the vicinity have increased their activity. The Transcript says that there are dozens of mines that have heretofore been extensively worked, but failed to pay as largely as owners desired, and have for some time been shut down. The owners believe with the Fryer process they will pay first-rate. There are also some mines that always paid well, but by mismanagement became involved and were shut down. The Banner mine will, it is thought, be opened before long. There has been over \$800,000 taken out of it, and not one assessment levied during the time. The ledge at the point last worked was, we believe, eight feet in width, and if it can be reduced as cheaply as Mr. Fryer proposes to work, it would pay a clear profit of between ten and fifteen dollars, even if the process only saved as much gold as the old mill process, which in that case did not secure over 30 to 35 per cent.

As the new process will shortly be tried on an extensive scale, we hope soon to be able to lay the results before our readers, together with some description of the process itself.

Ourselves.

This issue of the MINING AND SCIENTIFIC PRESS closes Volume XXX. We hope we have given satisfaction to our readers and intend trying to continue to do so. The mining interests of the coast were never before in so prosperous a condition as now, and never were so many engaged in it as a legitimate business. It is our endeavor to represent this important class of the community, and collect all the information of interest to them. Leaving aside the weekly mining news given in each issue, we have paid close attention to all new processes or improvements which are of value to miners and published them in a compact condensed form. The double sheet issue of this week alone is worth more than a year's subscription. The valuable and exhaustive article on lead, with the tables of lead minerals, prepared expressly for the Press by Mr. Hanks, is itself of great value. The paper this week also contains the United States Statutes relating to mining, which every miner should read closely, as they are of great importance. Our increasing list of practical correspondents who write on mining matters is a source of benefit to our readers and gratification to us. We do not consider it necessary to call attention to the work we have done for the mining community during the year, as it speaks for itself; but we desire to impress it upon miners generally that they cannot afford to do without a paper devoted to their special interests, and they should do all in their power to enhance its value and usefulness. Bring it to the attention of other miners, and assist it in any manner you can. The information in its columns, collected from all sources, is of far more value than the price of subscription. Those who are identified with the mining or industrial interests of the coast, who are not already subscribers, should become so now at the commencement of a new volume, and we promise them they shall not be disappointed in their investment.

LIVERPOOL COPPER MARKET.—We see by James Lewis & Sons' monthly report on ores and metals on the 1st inst., that owing to the uneasy feeling created by rumors of probable war on the continent, the copper market was in a very dull and apathetic state during the first half of May, and in the almost total absence of buyers, values of bars gradually receded from \$83 to \$81 6s. When the stocks of Chile copper were made up on the 14th ult., they were found to have decreased 898 tons. On the fear of war being allayed, an improved demand sprung up, and holders being firm, prices have gradually advanced to \$83 for good ordinary brands, and \$83 10s for picked brands to arrive, the sales being estimated at about 2,000 tons. Latest quotations were: Bars, \$82 10s. to \$83 cash; \$83 to \$83 10s. to arrive for good ordinary brands. Ore 16a 6d per unit. Regulars 17a., and Barilla 18a. 3d per unit.

Removing Broken Drills from Holes.

John W. Platt, of Mineral City, Nevada, has recently patented through the agency connected with this office a device for removing stubs and broken pieces of drills from holes, which is of interest to the mining community. It consists in the employment of a pair of jaws so shaped that they can be introduced around the stub and then firmly closed so as to hold and withdraw it. The operating mechanism is enclosed and protected by a case. Two gripping jaws are so curved as to form cylindrical sections, with roughened inner faces. The ends of these jaws are tapered to a blunt apex, and they are scarfed to an edge also, this being for the purpose of making it easy to work the jaws down through the rock and dirt that may be in the hole surrounding the stub. The sides of the jaws taper toward each other at the top, and unite so as to form a transverse cylindrical head. This head is fitted into a hole bored transversely through the lower end of the stem and a slot opens downward from the hole to allow the sides of the jaws to pass in. The stem passes up through a cylindrical sleeve, or case, within which it is protected, and the upper end of the stem has a screw cut upon it, so that the handle or elongated nut can be turned up or down as desired. A stationary handle is fixed to the top of the stem, and by this it is held while the nut is being turned.

This device is operated as follows: If a drill becomes broken in the hole the nut is turned back, and the elasticity of the sides of the jaws causes them to spread apart, and draw out of the case until they are sufficiently well opened to pass down upon each side of the drill. The stem is now twisted from side to side by means of its handles and the jaws will be worked down upon each side of the broken stub so as to clasp it. Now by turning the nut or handle, the cylindrical case will be forced down over the jaws, thus forcing them together and causing them to compress the steel firmly, so that the whole can be withdrawn, the operation not occupying more than a minute or two, even in holes three or four feet deep.

If the jaws should become broken or injured it will be only necessary to remove the handle and nut so as to allow the stem to be slipped out, when the head will easily slide from its socket, and can be replaced by another.

Work at the Foundries.

There seems to be no abatement in the continued demand upon the capacity of our foundries. The amount of business brought to our city by the mining interests of California and Nevada is made peculiarly evident in the flourishing state of business at these establishments.

Pacific Iron Works.

At these works the immense hoisting apparatus for the California and Consolidated Virginia shaft has been completed and was shipped on Tuesday of this week. The apparatus is the largest of the kind ever manufactured in this country. It has a hoisting capacity of 4,000 feet. There are two engines, twenty-six inch bore, six feet stroke, fitted with balance poppet valves and cross cut-off. The cylinders weigh 16,000 pounds each. There is to be one engine on each end of the shaft, the distance between being twenty-four feet from center to center. Double reels for flat wire rope are to be used. The engines are to be fitted with two steam brakes, one for each reel, with an independent hand brake for each reel. Six tubular boilers go with the machinery, fifty-four inches in diameter and sixteen feet long.

These hoisting works are fitted up with the latest improvements, finished in the best style, and will reflect credit not only upon the works constructing them, but upon the mechanical skill of the Pacific coast.

The managers of the Pacific Iron Works have lately contracted to build a pair of engines, 10x20 inch, for a mine in Sonora, Mexico, together with a ten stamp mill, pans, settlers, etc.

Nanaimo Coal.

Mr. Selwyn, F. R. S., Director of the Geological Survey of Canada, writes to the American Journal of Science and Arts on the age of the lignite coal formation of Vancouver island. He says: "I wish to record my dissent from the statement made by Professor Lesquereux, page 365 of Dr. Hayden's Report on the United States Geological and Geographical Survey of Colorado, 1873, to the effect that the coal of Nanaimo, Vancouver island, is referable to the lower American loocene. Careful surveys have now been made by the Canadian Geological Survey of the Nanaimo coal basin, and it is proved beyond the possibility of a doubt that the coal beds there are overlaid by a succession of strata, shales, sandstones and conglomerates, having a thickness of nearly 4,000 feet, and holding from base to summit marine cretaceous fossils, ammonites, baculites, inocerami and others. Maps and sections, showing the relative position of these beds and of the coal seams are given in the Report of the Geological Survey of Canada, 1872-1873; and I would beg to refer Prof. Lesquereux to them for information concerning the coal rocks of Vancouver island. As he makes no reference to the Report named I conclude he has not seen it."

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

IMPROVED POTATO DIGGER.—Jas. J. McKinnon, San Francisco, Cal. The rear end of the frame of this improved implement (supported on bearing wheels in the usual way) is in the form of an inverted U, and the rear leg of the inverted U extends down to the ground so as to form a standard for the shovel or plow which lifts the potatoes out of the ground. Hauls are secured to the rear end of the frame, by means of which a person walking on the rear of the plow can raise or lower the rear end of the frame at will in order to force the plow into the ground or force it out. The plow is made in the form of a shovel or scow, with a curved upper surface. A bevel wheel is secured to the axle inside of the frame, so that it turns with the axle. A shaft has its rear end supported on the standard above the plow and extends along under the frame to a cross bar of the frame in which its forward end is supported. To the forward end of this shaft a bevel pinion is secured, so as to engage with the bevel wheel. To the rear end of the shaft inside of the inverted U, is secured a four-armed wheel, the arms of which are long enough to pass close to the upper concave surface of the shovel. When the machine moves forward this shaft is rotated by the bevel gears, and consequently the wheel is caused to rotate above the plow and at right angles to the travel of the machine. When the shovel is forced into the ground under the potato hills, and drawn along the row, it will lift the hills of potatoes and carry them up over the rear end of the shovel, but the revolving arms of the wheel will strike the furrow as it is lifted into the hollow of the shovel and thus throw the potatoes and dirt out to one side of the furrow, leaving the potatoes upon the surface of the ground so that they can be easily picked up. The inventor states that this machine has proved very effective for unearthing potatoes and leaving them in a position ready to be picked up.

FEEDERS FOR THRESHING MACHINES.—Byron Jackson, Woodland, Yolo county, Cal. This is an improvement for delivering unthreshed straw to the cylinder of threshing machines, and is based more especially on a patent granted to W. J. Sloan, Sept. 3d, 1867, in which a moving belt or carrier conveys the grain to the cylinder, and a revolving shaft or drum armed with teeth is intended to regulate the delivery of the straw. It is found, however, that when a large bunch strikes the picker, it will remain until forced onward by other straw from behind, when it will pass through without being separated, and when the machine is operating where there are prevalent high winds, as in some parts of California, the straw will be blown upon the picker, around which it becomes twisted so that the machine must be stopped to disentangle it. In order to obviate this difficulty Mr. Jackson constructs his feeder with a short inclined belt, which stands above the discharge end of the feeding belt in place of the picker, and assists in guiding the direction of the straw to the cylinder.

DISTRIBUTOR FOR STRAW CARRIERS.—This is another improvement by the above named inventor, relating to straw carriers such as are employed to bring straw from the stack to the feeder, which is attached to the machine to supply the cylinder. The improvement consists in the use of a short belt standing at an angle above the main carrying belt, and made to revolve in an opposite direction. This belt may be adjusted up and down, and is provided with points or pickers which serve to catch and force back any masses of straw, until they fall into some place where there is little straw, and thus the straw which is thrown upon this belt in bunches, or forks, will be properly distributed before it reaches the feeder, and will be delivered to the latter in a comparatively even flow.

VACUUM RELIEF VALVE FOR WATER PIPES.—Philip Hinkle, San Francisco, Cal. This invention relates to a novel relief valve for water pipes, by which the inventor is enabled to prevent the heavy jar caused by the sudden shutting off of running water in pipes, where a vacuum is produced by its running. The invention consists of an inwardly opening valve, snitely attached, which is kept closed by a light spring and the pressure of water inside the pipe. When this latter pressure is removed by the vacuum caused by the flow of the water, the pressure of air outside of the valve will open it and allow air to enter and relieve any jar.

THE San Vicente lime company, at Santa Cruz, are building a new wharf 1,000 feet long, for the purpose of shipping the lime, and they propose using the new steamer *San Vicente* for carrying it to market. They think that when they get to working well that they will turn out from 9,000 to 10,000 barrels of lime per month.

ANTIMONY is selling in Liverpool at £58 to £60 per ton for French Star regulars.

DOUBLE SHEET—24 PAGES.

Portable Sawmill.

No machine has done more for the rapid development of this country than the portable circular sawmill. These are made in large numbers throughout the Central States, some of which are, however, of ordinary construction, others, the product of leaders in this line, are very superior and embrace features which by patent are controlled exclusively. Such a mill as this is made by Messrs. Lane & Bodley, of Cincinnati, and is represented in the accompanying fine engraving.

This firm makes iron frame mills only, contending that their first cost need not greatly exceed that of wood frames, while the advantage of solidity and durability, the absence of joints and the consequent impossibility that the bearings should become misplaced and out of their true lines, are so evident to the mechanic that more than a mention of this construction is unnecessary.

Other important features we will notice on leaving the frame in the order of their position. All bearings are filled with anti friction metal, those of the mandrels being self-lubricating,

and of such simple construction as to run constantly so long as supplied with oil, no wick, cotton or wool being used.

The saw mandrels are of the best iron or steel and are held in position laterally by a patented semi-elastic collar bearing.

The friction feed is here shown in its simplicity and strength. One belt only is required, that to drive the feed; the friction faces are ample and all shafts have long bearings. A control of the carriage is given by this arrangement that is not found elsewhere—the motion of a lever forward or backward moves the carriage at a speed governed by the will of the Sawyer, allowing the feed to be slackened as a knot is reached, and permitting a very fast return of the carriage for a new board set.

This firm by preference run the carriages of their best mills over rollers lying on chains upon the sills. This gives a large bearing surface, has a bearing always under the portion of the log being cut, and entirely avoids the jumping of the track because of sawdust or chips.

The setting works or head blocks are of a peculiar construction, yet so simple as to be readily understood. This portion of a sawmill is generally of the greatest interest, as it is by defective construction of these that the user is most seriously annoyed.

Lightness and strength are desirable; this is attained by the use of wrought iron as a base for the block, this by preference is in the strong-

est form known. The knees or standards are moved by coarse thread screws, power on which is obtained by a pair of gear wheels at one end, of suitable proportions.

The advantages of a screw set is its accuracy, and the objection only the supposed lack of speed. A springing log cannot draw forward a knee on a screw block, yet can on any other.

Upon the mill shown the speed of movement is greatly increased by the manner of connecting the blocks and of converting the reciprocating motion of the setting bar with a rotary motion upon the screws. This is accomplished by an upper and lower set of pawls attached to a reciprocating bar working alternately upon a ratchet wheel of coarse pitch, of which one tooth represents one-sixteenth of an inch upon the knee.

The automatic dog is a novel in form, the hook is swiveled so that it can be made to enter the log upon either side of the knee, these will hold securely the largest log or the last fitch, and will permit the saw to cut within one-half an inch of the knee. When once inserted the dog can not back out. When the hook is released the dog immediately returns to a secure position entirely out of the way of the saw or the fresh log.

It will be noticed that nowhere on the setting apparatus is metal used torsionally, although the practice is common. Messrs. Lane & Bodley consider that the use of metal in this way

on a head block is as much out of place as upon a pair of scales, in fact they consider that their blocks might be likened to a pair of scales in their accuracy.

The mill shown will carry a seventy-two-inch lever and a thirty-inch top saw. The yoke carrying the top saw is adjusted vertically by a single hand wheel, the convenience of this where saws are changed instead of filed upon the mandrel is very great. The length of the head blocks generally used on this mill permit an opening of forty-eight inches between the knee and saw, but can be made greater if desirable—an accommodation which the wrought iron beam permits.

The log trusser shown in the engraving is a new idea which is now undergoing a thorough test before being put upon the market; the results now reached are so highly satisfactory that they have no doubt of the future success of the device.

Altogether this mill is well adapted to the wants of the Pacific coast, where large logs abound and a great demand for bill timber exists. The suitability of this mill for the latter purpose is most apparent in the setting works, which the makers guarantee to be as accurate on a sixty-foot carriage as on a twenty-foot one. Parties interested will receive prompt attention to the correspondence they may address the firm at Cincinnati. Circulars sent upon application.

LANE & BODLEY'S IMPROVED SAW-MILL.

Revised Statutes of the United States, Relating to Mineral Lands and Mining Resources.

EXPLANATION.—RELATION OF THE REVISED STATUTES TO REPEALED LAWS.

In the recently issued Revised Statutes of the United States, all the laws relating to mineral lands are brought together in chapter six of title thirty-two (Public Lands), and all those portions of the Acts of July 26th, 1866, July 9th, 1870 and May 10th, 1872, which had not been repealed previously, together with the Coal Land Act of March 3d, 1874, are consolidated in the chapter referred to, as herewith reprinted. We have also, in examining the Revised Statutes, selected such collateral sections as have reference to mineral lands and print them here under the title of "Miscellaneous Provisions."

In order that the reader may distinctly understand the relations which these Revised Statutes bear to the Acts previously in force, we give the following extract from the "Repealing Provisions," approved June 22d, 1874. This provision will be found on page 1091 of the Revised Statutes, section 5596, and repeals certain Acts passed prior to December 1st, 1873.

"SECTION 5596. REPEAL OF ACTS ENACTED IN REVISED STATUTES.—All Acts of Congress passed prior to said 1st day of December, one thousand eight hundred and seventy-three, any portion of which is embraced in any section of said revision, are hereby repealed, and the action applicable thereto shall be in force in lieu thereof; all parts of said Acts not contained in such revision, having been repealed or superseded by subsequent Acts, or not being general or permanent in their nature. *Provided*, That the incorporation into said revision of other provisions of a private, local, or temporary character, shall not repeal or in any way affect any appropriation, or any provision of a private, local, or temporary character, contained in any of said Acts, but the same shall remain in force; and all Acts of Congress passed prior to said last named day, no part of which are embraced in said revision, shall not be affected or changed by its enactment."

This section, of course, virtually repeals the Acts of July 26th, 1866, July 9th, 1870 and May 10th, 1872, as well as all miscellaneous provisions except such as are specified in the above provision. No changes, however, were made in existing laws, the different provisions in force merely being re-arranged under proper titles. The arrangement and classification of the several sections of the Revised Statutes have only been made for the purpose of more convenient and orderly arrangement of the same. The repeal of the several Acts embraced in said revision does not affect any act done or any right accruing or accrued, or any suit or proceeding had or commenced in any civil cause before the said repeal, but all rights and liabilities under said Acts continue, and may be enforced in the same manner as if said repeal had not been made. The revision does not affect or repeal any Act of Congress passed since December 1st, 1873, and all Acts passed since that date are to have full effect as if passed after the enactment of the revision, and so far as any such Acts vary from or conflict with any provision contained in said revision, they are to have effect as subsequent Statutes, and as repealing any portion of the revision inconsistent therewith. It will be seen from this the "Revised Statutes," which are now in force simply embrace the Statutes of the United States, general and permanent in their nature, in force on the 1st day of December, 1873, as revised and consolidated by Commissioners appointed under an Act of Congress.

We have placed a short explanatory note, in brackets, over each section of the Revised Statutes, showing the difference, where there is any, in the wording of the particular section of the Revised Statutes and the corresponding section of the original Act of Congress from which it is derived.

Mineral Lands Reserved.

Sec. 2318. In all cases, lands valuable for minerals shall be reserved from sale, except as otherwise expressly directed by law.

Mineral Lands Open to Purchase by Citizens.

[This section is identical with Sec. 1 of the Act of May 10th, 1872, and almost identical with Sec. 1 of the Act of July 26th, 1866, which latter section was repealed by the Act of May 10th, 1872.]

Sec. 2319. All valuable mineral deposits in lands belonging to the United States, both surveyed and unsurveyed, are hereby declared to be free and open to exploration and purchase, and the lands in which they are found to occupation and purchase, by citizens of the United States and those who have declared their intention to become such, under regulations prescribed by law, and according to the local customs or rules of miners in the several mining districts, so far as the same are applicable and not inconsistent with the laws of the United States.

Length of Mining Claims Upon Veins or Lodes.

[This section is the same as Sec. 2 of the Act of May 10th, 1872.]

Sec. 2320. Mining claims upon veins or lodes of quartz or other rock in place bearing gold, silver, cinnabar, lead, tin, copper, or other valuable deposits, heretofore located, shall be governed as to length along the vein or lode by the customs, regulations, and laws in force at the date of their location. A mining claim located after the tenth day of May, eighteen hundred and seventy-two, whether located by one or more persons, may equal, but shall not exceed, one thousand five hundred feet in length along the vein or lode; but no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located. No claim shall extend more than three hundred feet on each side of the middle of the vein at the surface, nor shall any claim be limited by any mining regulation to less than twenty-five feet on each side of the middle of the vein at the surface, except where adverse rights existing on the tenth day of May, eighteen hundred and seventy-two, render such limitation necessary. The end-lines of each claim shall be parallel to each other.

Proof of Citizenship.

[This is the same as the last clause in Sec. 7 of the Act of May 10th, 1872, except that that clause had an addition which has been incorporated in Section 2326 of the Revised Statutes. The first part of Sec. 7 of the Act of May 10th, 1872, will also be found incorporated in section 2326.]

Sec. 2321. Proof of citizenship, under this chapter, may consist, in the case of an individual, of his own affidavit thereof; in the case of an association of persons unincorporated, of the affidavit of their authorized agent, made on his own knowledge, or upon information and belief; and in the case of a corporation organized under the laws of the United States, or of any State or Territory thereof, by the filing of a certified copy of their charter or certificate of incorporation.

Locators' Rights of Possession and Enjoyment.

[This is identical with Sec. 3 of the Act of May 10th, 1872.]

Sec. 2322. The locators of all mining locations heretofore made, or which shall hereafter be made, on any mineral vein, lode, or ledge, situated on the public domain, their heirs and assigns, where no adverse claim exists on the tenth day of May, eighteen hundred and seventy-two, so long as they comply with the laws of the United States, and with State, Territorial, and local regulations not in conflict with the laws of the United States governing their possessory title, shall have the exclusive right of possession and enjoyment of all the surface included within the lines of their locations, and of all veins, lodes, and ledges throughout their entire depth, the top or apex of which lies inside of such surface-lines extended downward vertically, although such veins, lodes, or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side-lines of such surface locations. But their right of possession to such outside parts of such veins or ledges shall be confined to such portions thereof as lie between vertical planes drawn downward as above described, through the end-lines of their loca-

tions, so continued in their own direction that such planes will intersect such exterior parts of such veins or ledges. And nothing in this section shall authorize the locator or possessor of a vein or lode which extends in its downward course beyond the vertical lines of his claim to enter upon the surface of a claim owned or possessed by another.

Owners of Tunnels, Rights of.

[This section is the same as Sec. 4 of the Act of May 10th, 1872.]
 Sec. 2323. Where a tunnel is run for the development of a vein or lode, or for the discovery of mines, the owners of such tunnel shall have the right of possession of all veins or lodes within three thousand feet from the face of such tunnel on the line thereof, not previously known to exist, discovered in such tunnel, to the same extent as if discovered from the surface; and locations on the line of such tunnel of veins or lodes not appearing on the surface, made by other parties after the commencement of the tunnel, and while the same is being prosecuted with reasonable diligence, shall be invalid; but failure to prosecute the work on the tunnel for six months shall be considered as an abandonment of the right to all undiscovered veins on the line of such tunnel.

Miners' Regulations; Expenditures and Improvements.

[This section is the same as Sec. 5 of the Act of May 10th, 1872, except that in the clause relating to expenditures in that Act, the words "each year for each hundred feet" were used instead of the words "by the 10th day of June, 1874, and each year thereafter." It will be remembered that on March 1st, 1873, Congress passed an Act amending that of May 10th, 1872, so that the time for the first annual expenditures on claims located prior to the passage of the Act, was extended to June 10th, 1873. Again on June 6th, 1874, Congress again amended the 6th section of the Act so that the time for the first annual expenditure on such claims was extended to January 1st, 1875.]
 Sec. 2324. The miners of each mining district may make regulations not in conflict with the laws of the United States, or with the laws of the State or Territory in which the district is situated, governing the location, manner of recording, amount of work necessary to hold possession of a mining claim, subject to the following requirements: The location must be distinctly marked on the ground so that its boundaries can be readily traced. All records of mining-claims hereafter made shall contain the name or names of the locators, the date of the location, and such a description of the claim or claims located by reference to some natural object or permanent monument as will identify the claim. On each claim located after the tenth day of May, eighteen hundred and seventy-two, and until a patent has been issued therefor, not less than one hundred dollars' worth of labor shall be performed or improvements made during each year. On all claims located prior to the tenth day of May, eighteen hundred and seventy-two, ten dollars' worth of labor shall be performed or improvements made by the tenth day of June, eighteen hundred and seventy-four, and each year thereafter, for each one hundred feet in length along the vein, until a patent has been issued therefor; but where such claims are held in common, such expenditure may be made upon any one claim; and upon a failure to comply with these conditions, the claim or mine upon which such failure occurred shall be open to relocation in the same manner as if no location of the same had ever been made, provided that the original locators, their heirs, assigns, or legal representatives, have not resumed work upon the claim after failure and before such location. Upon the failure of any one of several co-owners to contribute his proportion of the expenditures required hereby, the co-owners who have performed the labor or made the improvements, may, at the expiration of the year, give such delinquent co-owner personal notice in writing, or notice by publication in the newspaper published nearest the claim, for at least once a week for ninety days, and if, at the expiration of ninety days after such notice in writing or by publication, such delinquent should fail or refuse to contribute his proportion of the expenditure required by this section, his interest in the claim shall become the property of his co-owners who have made the required expenditures.

The following Act of Congress, which was passed since the revision of the Statutes, being approved February 11th, 1875, is introduced here, as it affects the above section:
 An Act to amend Section 2324 of the Revised Statutes, relating to the development of the mining resources of the United States.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled: That Section two thousand three hundred and twenty-four of the Revised Statutes be, and is hereby, amended so that where a person or company has or may run a tunnel for the purposes of developing a lode or lodes, owned by said person or company, the money so expended in said tunnel shall be taken and considered as expended on said lode or lodes, whether located prior to or since the passage of said Act; and such person or company shall not be required to perform work upon the surface of said lode or lodes in order to hold the same as required by said Act.

After the passage of this Act, the Commissioner of the General Land Office ordered that "the expenditures required upon mining claims may be made from the surface or in running a tunnel for the development of such claims."

Patents for Mineral Lands, How Obtained.

[This section is the same as Sec. 6 of the Act of May 10th, 1872. See also Sections 2 and 3 of the Act of July 26th, 1866.]

Sec. 2325. A patent for any land claimed and located for valuable deposits may be obtained in the following manner: Any person, association, or corporation authorized to locate a claim under this chapter, having claimed and located a piece of land for such purposes, who has, or have, complied with the terms of this chapter, may file in the proper land-office an application for a patent, under oath, showing such compliance, together with a plat and field-notes of the claim or claims in common, made by or under the direction of the United States Surveyor General, showing accurately the boundaries of the claim or claims, which shall be distinctly marked by monuments on the ground, and shall post a copy of such plat, together with a notice of such application for a patent, in a conspicuous place on the land embraced in such plat, previous to the filing of the application for a patent, and shall file an affidavit of at least two persons that such notice has been duly posted, and shall file a copy of the notice in such land-office, and shall thereupon be entitled to a patent for the land, in the manner following: The register of the land-office, upon the filing of such application, plat, field-notes, notices, and affidavits, shall publish a notice that such application has been made, for the period of sixty days, in a newspaper to be by him designated as published nearest to such claim; and he shall also post such notice in his office for the same period. The claimant at the time of filing this application, or at any time thereafter, within the sixty days of publication, shall file with the register a certificate of the United States Surveyor General that five hundred dollars' worth of labor has been expended, or improvements made upon the claim by himself or grantors; that the plat is correct, with such further description by such reference to natural objects or permanent monuments as shall identify the claim, and furnish an accurate description, to be incorporated in the patent. At the expiration of the sixty days of publication the claimant shall file his affidavit, showing that the plat and notice have been posted in a conspicuous place on the claim during such period of publication. If no adverse claim shall have been filed with the register and the receiver of the proper land-office at the expiration of the sixty days of publication, it shall be assumed that the applicant is entitled to a patent, upon the payment to the proper officer of five dollars per acre, and that no adverse claim exists; and thereafter no objection from third parties to the issuance of a patent shall be heard, except it be shown that the applicant has failed to comply with the terms of this chapter.

Adverse Claim, Proceedings on.

[This corresponds with Sec. 7 of the Act of May 10th, 1872, except that the provision relating to rights of citizenship is taken out and is now a separate section, 2321, of the Revised Statutes.]

Sec. 2326. Where an adverse claim is filed during the period of publication, it shall be upon oath of the person or persons making the same, and shall show the nature, boundaries, and extent of such adverse claim, and all proceedings, except the publication of notice and making and filing of the affidavit thereof, shall be stayed until the controversy shall have been settled or decided by a court of competent jurisdiction, or the adverse claim waived. It shall be the duty of the adverse claimant, within thirty days after filing his claim, to commence proceedings in a court of competent jurisdiction, to determine the question of the right of possession, and prosecute the same with reasonable diligence to final judgment; and a failure so to do shall be a waiver of his adverse claim. After such judgment shall have been rendered, the party entitled to the possession of the claim, or any portion thereof, may, without giving further notice, file a certified copy of the judgment-roll with the register of the land-office, together with the certificate of the Surveyor General that the requisite amount of labor has been expended, or improvements made thereon, and the description required in other cases, and shall pay to the receiver five dollars per acre for his claim, together with the proper fees, whereupon the whole proceedings and the judgment-roll shall be certified by the register to the Commissioner of the General Land Office, and a patent shall issue thereon for the claim, or such portion thereof as the applicant shall appear, from the decision of the court, to rightly possess. If it appears from the decision of the court, that several parties are entitled to separate and different portions of the claim, each party may pay for his portion of the claim, with the proper fees, and file the certificate and description by the Surveyor General, whereupon the register shall certify the proceedings and judgment-roll to the Commissioner of the General Land Office, as in the preceding case, and patents shall issue to the several parties according to their respective rights. Nothing herein contained shall be construed to prevent the alienation of the title conveyed by a patent for a mining claim to any person whatever.

Description of Vein Claims on Surveyed and Unsurveyed Lands.

[Same as Sec. 8 of Act of May 10th, 1872.]

Sec. 2327. The description of vein or lode claims, upon surveyed lands, shall designate the location of the claim with reference to the lines of the public surveys, but need not conform therewith; but where a patent shall be issued for claims upon unsurveyed lands, the surveyor-general, in extending the surveys, shall adjust the same to the boundaries of such patented claim, according to the plat or description thereof, but so as in no case to interfere with or change the location of any such patented claim.

Pending Applications; Existing Rights.

[This formed part of Sec. 9 of the Act of May 10th, 1872, the paragraph which is left out here, simply repealing Sections 1, 2, 3, 4 and 6 of the Act of July 26th, 1866, the repeal not affecting existing rights. The words

"patents for mining claims" in the 9th section of the Act of May 10th, 1872, are here changed to "patents for mining claims on veins or lodes."]

Sec. 2328. Applications for patents for mining claims, under former laws now pending, may be presented to a final decision in the General Land-Office; but in such cases where adverse rights are not affected thereby, patents may issue in pursuance of the provisions of this chapter; and all patents for mining claims upon veins or lodes heretofore issued shall convey all the rights and privileges conferred by this chapter, where no adverse rights existed on the tenth day of May, eighteen hundred and seventy-two.

Conformity of Placer Claims to Surveys; Limit of.

[This section corresponds to the first clause of Sec. 12, Act of July 9th, 1870.]

Sec. 2329. Claims usually called "placers," including all forms of deposit, excepting veins of quartz, or other rock in place, shall be subject to entry and patent, under like circumstances and conditions, and upon similar proceedings, as are provided for vein or lode claims; but where the lands have been previously surveyed by the United States, the entry in its exterior limits shall conform to the legal subdivisions of the public lands.

Subdivision of Ten-Acre Tracts; Limit of Placer Locations.

[This section is substantially the same as the latter part of Sec. 12, Act of July 9th, 1870.]

Sec. 2330. Legal subdivisions of forty acres may be subdivided into ten-acre tracts; and two or more persons, or associations of persons, having contiguous claims of any size, although such claims may be less than ten acres each, may make joint entry thereof; but no location of a placer claim, made after the ninth day of July, eighteen hundred and seventy, shall exceed one hundred and sixty acres for any one person or association of persons, which location shall conform to the United States surveys; and nothing in this section contained shall defeat or impair any bona-fide pre-emption or homestead claim upon agricultural lands, or authorize the sale of the improvements of any bona-fide settler to any purchaser.

Survey of Placer Claims; Limitation of.

[The basis of this section may be found in Sec. 10, Act of May 10th, 1872, and Sec. 16, Act of July 9th, 1870.]

Sec. 2331. Where placer claims are upon surveyed lands, and conform to legal subdivisions, no further survey or plat shall be required, and all placer mining claims located after the tenth day of May, eighteen hundred and seventy-two, shall conform as near as practicable with the United States system of public-land surveys, and the rectangular subdivision of such surveys, and no such location shall include more than twenty acres for each individual claimant; but where placer claims cannot be conformed to legal subdivisions, survey and plat shall be made as on unsurveyed lands; and where by the segregation of mineral land in any legal subdivision, a quantity of agricultural land less than forty acres remains, such fractional portion of agricultural land may be entered by any party qualified by law, for homestead or pre-emption purposes.

Evidence of Possession to Establish Right to Patent.

[This section is the same as Sec. 13 of the Act of July 9th, 1870, except that the words "this chapter" are inserted instead of "this Act."]

Sec. 2332. Where such person or association, they and their grantors, have held and worked their claims for a period equal to the time prescribed by the statute of limitations for mining claims of the State and Territory where the same may be situated, evidence of such possession and working of the claims for such period shall be sufficient to establish a right to a patent thereunder this chapter, in the absence of any adverse claim; but nothing in this chapter shall be deemed to impair any lien which may have attached in any way whatever to any mining claim or property thereto attached prior to the issuance of a patent.

Proceedings for Patent for Placer Claim, Etc.

[This is the same as Sec. 11 of the Act of May 10th, 1872, except that the words "subject to the provisions of this chapter," are inserted instead of the words "subject to the provisions of this Act and an Act to amend, etc., approved July 9th, 1870."]

Sec. 2333. Where the same person, association or corporation is in possession of a placer claim, and also a vein or lode included within the boundaries thereof, application shall be made for a patent for the placer claim, with the statement that it includes such vein or lode, and in such case a patent shall issue for the placer claim, subject to the provisions of this chapter, including such vein or lode, upon the payment of five dollars per acre for such vein or lode claim, and twenty-five feet of surface on each side thereof. The remainder of the placer claim, or any placer claim not embracing any vein or lode claim, shall be paid for at the rate of two dollars and fifty cents per acre, together with all costs of proceedings; and where a vein or lode, such as is described in section twenty-three hundred and twenty, is known to exist within the boundaries of a placer claim, an application for a patent for such placer claim, which does not include an application for the vein or lode claim shall be construed as a conclusive declaration that the claimant of the placer claim has no right of possession of the vein or lode claim; but where the existence of a vein or lode in a placer claim is not known, a patent for the placer claim shall convey all valuable mineral and other deposits within the boundaries thereof.

Surveyor-General to Appoint Surveyors of Mining Claims.

[This is the same as the first half of Sec. 12, of the Act of May 10th, 1872. The remainder of Sec. 12 of the Act of May 10th, 1872 referred to the fees of registers and receivers, which subject is more fully detailed in Sec. 2335, given under the head of "Miscellaneous Provisions." The remainder of Sec. 12 also specified that nothing in that Act should be construed to enlarge or affect the rights of either party at the time of the passage of the Act of May 10th, 1872, or Act of July 26th, 1866; also that nothing in the Act be construed to repeal, impair or in any way affect the Act passed July 25th 1866, granting a. Suto the right of way and other privileges to aid in the construction of a draining and exploring tunnel to the Comstock lode, in the State of Nevada.]

Sec. 2334. The Surveyor General of the United States may appoint in each land-district containing mineral lands as many competent surveyors as shall apply for appointment to survey mining claims. The expenses of the survey of vein or lode claims, and the survey and subdivision of placer claims into smaller quantities than one hundred and sixty acres, together with the cost of publication of notices, shall be paid by the applicants, and they shall be at liberty to obtain the same at the most reasonable rates, and they shall also be at liberty to employ any United States deputy surveyor to make the survey. The Commissioner of the General Land-Office shall also have power to establish the maximum charges for surveys and publication of notices under this chapter; and, in case of excessive charges for publication, he may designate any newspaper published in a land-district where mines are situated, for the publication of mining-notices in such district, and fix the rates to be charged by such paper; and to the end that the Commissioner may be fully informed on the subject, each applicant shall file with the register a sworn statement of all charges and fees paid by such applicant for publication and surveys, together with all fees and money paid the register and the receiver of the land-office, which statement shall be transmitted with the other papers in the case to the Commissioner of the General Land-Office.

Verification of Affidavits, Etc.

[This is the same as Sec. 13, Act of May 10th, 1872, except that the words "this chapter" are inserted instead of "this Act," etc.]

Sec. 2335. All affidavits required to be made under this chapter may be verified before any officer authorized to administer oaths within the land-district where the claims may be situated, and all testimony and proofs may be taken before any such officer, and when duly certified by the officer taking the same, shall have the same force and effect as if taken before the register and receiver of the land-office. In cases of contest as to the mineral or agricultural character of land the testimony and proofs may be taken as herein provided, on personal notice of at least ten days to the opposing party; or if such party cannot be found, then by publication of at least once a week for thirty days in a newspaper, to be designated by the register of the land-office as published nearest to the location of such land; and the register shall require proof that such notice has been given.

Where Veins Intersect, Etc.

[This is the same as Sec. 14, Act of May 10th, 1872, except that the word "but" is substituted for "provided."]

Sec. 2336. Where two or more veins intersect or cross each other, priority of title shall govern, and snoh prior location shall be entitled to all ore or mineral contained within the space of intersection; but the subsequent location shall have the right of way through the space of intersection for the purposes of the convenient working of the mine. And where two or more veins unite, the oldest or prior location shall take the vein below the point of union, including all the space of intersection.

Patents for Non-Mineral Lands, Etc.

[This is the same as Sec. 16, Act of May 10th, 1872, except that the word "but" is substituted for "provided."]

Sec. 2337. Where non-mineral land not contiguous to the vein or lode is used or occupied by the proprietor of such vein or lode for mining or milling purposes, such non-adjacent surface ground may be embraced and included in an application for a patent for such vein or lode, and the same may be patented therewith, subject to the same preliminary requirements as to survey and notice as are applicable to veins or lodes; but no location hereafter made of such non-adjacent land shall exceed five acres, and payment for the same must be made at the same rate as fixed by this chapter for the superficies of the lode. The owner of a quartz-mill or reduction-works not owning a mine in connection therewith may also receive a patent for his mill-site, as provided in this section.

State or Territorial Legislation Concerning Mineral Lands.

[Same as Sec. 5 of Act of July 26th, 1866.]

Sec. 2338. As a condition of sale in the absence of necessary legislation by Congress, the local legislature of any State or Territory may provide rules for working mines, involving easements, drainage, and other necessary means to their complete development; and those conditions shall be fully expressed in the patent.

Vested Rights to Use of Water; Right of Way for Canals, Etc.

[Same as Sec. 9 of Act of July 26th, 1866.]

Sec. 2339. Whenever, by priority of possession, rights to the use of water for mining, agri-

cultural, manufacturing, or other purposes, have vested and accrued, and the same are recognized and acknowledged by the local customs, laws, and the decisions of courts, the possessors and owners of such vested rights shall be maintained and protected in the same; and the right of way for the construction of ditches and canals for the purposes herein specified is acknowledged and confirmed; but whenever any person, in the construction of any ditch or canal, injures or damages the possession of any settler on the public domain, the party committing such injury or damage shall be liable to the party injured for such injury or damage.

Patents, Etc., Subject to Vested Water-Rights.

[Same as part of Sec. 17 of Act of July 9th, 1870.]

Sec. 2340. All patents granted, or pre-emption of homesteads allowed, shall be subject to any vested and accrued water-rights, or rights to ditches and reservoirs used in connection with such water-rights, as may have been acquired under or recognized by the preceding action.

Non-Mineral Lands Open to Homesteads.

[This is substantially the same as Sec. 10, Act of July 26th, 1866, except that after the words "160 acres," the following words are omitted: "Or said parties may avail themselves of the provisions of the Act of Congress of May 20th, 1862, entitled an Act to secure homesteads to actual settlers on the public domain, and Acts amendatory thereof." The laws referred to in the last two lines of Sec. 2341, may be found under chapter 5, title 32, pages 423, 424, 425, and 426, Revised Statutes of United States.]

Sec. 2341. Wherever, upon the lands heretofore designated as mineral lands, which have been excluded from survey and sale, there have been homesteads made by citizens of the United States, or persons who have declared their intention to become citizens, which homesteads have been made, improved, and used for agricultural purposes, and upon which there have been no valuable mines of gold, silver, cinnabar, or copper discovered, and which are properly agricultural lands, the settlers or owners of such homesteads shall have a right of pre-emption thereto, and shall be entitled to purchase the same at the price of one dollar and twenty-five cents per acre, and in quantity not to exceed one hundred and sixty acres; or they may avail themselves of the provisions of chapter five of this title relating to "Homesteads."

Mineral Lands, How Set Apart as Agricultural.

[Same as Sec. 11 of Act of July 26th, 1866.]

Sec. 2342. Upon the survey of the lands described in the preceding section, the Secretary of the Interior may designate and set apart such portions of the same as are clearly agricultural lands, which lands shall thereafter be subject to pre-emption and sale as other public lands, and be subject to all the laws and regulations applicable to the same.

Power of the President to Provide Districts and Officers.

[Same as Sec. 7, of Act of July 26th, 1866, the words "this chapter" being substituted for "this Act."]

Sec. 2343. The President is authorized to establish additional land-districts, and to appoint the necessary officers under existing laws, wherever he may deem the same necessary for the public convenience in executing the provisions of this chapter.

Provisions of this Chapter not to Effect Certain Rights.

[Sec. 8 of Act of July 26th, 1866, says: "That the right of way for the construction of highways over public lands, not reserved for public uses, is hereby granted." Last clause of Sec. 16, Act of May 10th, 1871, says: "Nothing in this Act shall be construed to impair in any way, rights or interests in mining property acquired under existing laws." Sec. 6 of Act of March 3d, 1873 (Coal Land Law), says: "Nothing in this Act shall be construed to destroy or impair any rights which may have attached prior to its passage, or to authorize the sale of lands valuable for mines of gold, silver, or copper."]

Sec. 2344. Nothing contained in this chapter shall be construed to impair, in any way, rights or interests in mining property acquired under existing laws; nor to affect the provisions of the act entitled, "An act granting to A. Sotro the right of way and other privileges to aid in the construction of a draining and exploring tunnel to the Comstock lode, in the State of Nevada," approved July twenty-fifth, eighteen hundred and sixty-six.

Mineral Lands in Certain States Excepted.

Sec. 2345. The provisions in the preceding sections of this chapter shall not apply to the mineral lands situated in the States of Michigan, Wisconsin, and Minnesota, which are declared free and open to exploration and purchase, according to legal subdivisions in like manner as before the tenth day of May, eighteen hundred and seventy-two; and any bona-fide entries of such lands within the States named, since the tenth day of May, eighteen hundred and seventy-two, may be patented without reference to any of the foregoing provisions of this chapter. Such lands shall be offered for public sale in the same manner, at the same minimum price, and under the same rights of pre-emption as other public lands.

What Grants Not to Include Mineral Lands.

Sec. 2346. No act passed at the first session of the Thirty-eighth Congress, granting lands to States or corporations to aid in the construction of roads or for other purposes, or to extend the time of grants made prior to the thirtieth day of January, eighteen hundred and sixty-five, shall be so construed as to embrace mineral lands, which, in all cases are reserved exclusively to the United States, unless otherwise specially provided in the act or acts making the grant.

Entry of Coal Lands.

[Sec. 1 of Act of March 3d, 1873 (Coal Land Law), is identical with this section.]

Sec. 2347. Every person above the age of twenty-one years, who is a citizen of the United States, or who has declared his intention to become such, or any association of persons severally, qualified as above, shall, upon application to the register of the proper land-office, have the right to enter by legal subdivisions any quantity of vacant coal-lands of the United States not otherwise appropriated or reserved by competent authority, not exceeding one hundred and sixty acres to each individual person, or three hundred and twenty acres to such association, upon payment to the receiver of not less than ten dollars per acre, for such lands where the same shall be situated more than fifteen miles from any completed railroad, and not less than twenty dollars per acre for such lands as shall be within fifteen miles of such road.

Pre-emption of Coal Lands.

[Sec. 2 of Act of March 3d, 1873, is identical with this section.]

Sec. 2348. Any person or association of persons severally qualified as above provided, who have opened and improved, or shall hereafter open and improve any coal mine or mines upon the public lands, and shall be in actual possession of the same, shall be entitled to a preference-right of entry under the preceding section, of the mines so opened and improved: *Provided*, That when any association of not less than four persons, severally qualified as above provided, shall have expended not less than five thousand dollars in working and improving any such mine or mines, each association may enter not exceeding six hundred and forty acres, including such mining improvements.

Pre-emption of Coal Lands; When Claims to be Presented.

[Sec. 3 of Act of March 3d, 1873, is the same as this except that the words "under the preceding section" are substituted for the words "under section two of this Act."]

Sec. 2349. All claims under the preceding section must be presented to the register of the proper land-district within sixty days after the date of actual possession and the commencement of improvements on the land, by the filing of a declaratory statement therefor; but when the township plat is not on file at the date of such improvement, filing must be made within sixty days from the receipt of such plat at the district office; and where the improvements shall have been made prior to the expiration of three months from the third day of March, eighteen hundred and seventy-three, sixty days from the expiration of such three months shall be allowed for the filing of a declaratory statement, and no sale under the provisions of this section shall be allowed until the expiration of six months from the third day of March, eighteen hundred and seventy-three.

Only One Entry Allowed.

[Same as Sec. 4 of Act of March 3d, 1873, except that the words "the three preceding sections" are substituted for "that this Act."]

Sec. 2350. The three preceding sections shall be held to authorize only one entry by the same person or association of persons; and no association of persons, any member of which shall have taken the benefit of such sections, either as an individual or as a member of any other association, shall enter or hold any other lands under the provisions thereof; and no member of any association which shall have taken the benefit of such section shall enter or hold any other lands under their provisions; and all persons claiming under section twenty-three hundred and forty-eight shall be required to prove their respective rights and pay for the lands filed upon within one year from the time prescribed for filing their respective claims; and upon failure to file the proper notice or to pay for the land within the required period, the same shall be subject to entry by any other qualified applicant.

Conflicting Claims.

[Same as Sec. 5, Act of March 3d, 1873.]

Sec. 2351. In case of conflicting claims upon coal lands where the improvements shall be commenced after the third day of March, eighteen hundred and seventy-three, priority of possession and improvement, followed by proper filing and continued good faith, shall determine the preference-right to purchase. And also where improvements have already been made prior to the third day of March, eighteen hundred and seventy-three, division of the land claimed may be made by legal subdivisions, to include as near as may be the valuable improvements of the respective parties. The Commissioner of the General Land-Office is authorized to issue all needed rules and regulations for carrying into effect the provisions of this and the four preceding sections.

Existing Rights.

[Same as Sec. 6, Act of March 3d, 1873.]

Sec. 2352. Nothing in the five preceding sections shall be construed to destroy or impair any rights which may have attached prior to the third day of March, eighteen hundred and seventy-three, or to authorize the sale of lands valuable for mines of gold, silver, or copper.

MISCELLANEOUS PROVISIONS.

Possessory Actions Concerning Mining Titles.

Sec. 910. No possessory action between persons, in any court of the United States, for the recovery of any mining title, or for damages to any such title, shall be affected by the fact that the paramount title to the land in which such mines lie is in the United States; but each case shall be adjudged by the law of possession.

Registers' and Receivers' Fees and Commissions.

Sec. 2238. Registers and receivers, in addition to their salaries, shall be allowed each the following fees and commissions, namely:

1. A fee of one dollar for each declaratory statement filed and for services in acting on pre-emption claims.
2. A commission of one per centum on all moneys received at each receiver's office.
3. A commission to be paid by the homestead applicant, at the time of entry, of one per centum on the cash price, as fixed by law, of the land applied for; and a like commission when the claim is finally established, and the certificate therefor is issued as the basis of a patent.
4. The same commission on lands entered under any law to encourage the growth of timber on western prairies, as allowed when the like quantity of land is entered with money.
5. For locating military bounty land warrants, issued since the eleventh day of February, eighteen hundred and forty-seven, and for locating agricultural-college land-scrip, the same commission, to be paid by the holder or assignee of each warrant or scrip, as is allowed for sales of the public lands for cash, at the rate of one dollar and twenty-five cents per acre.
6. A fee, in donation cases, of five dollars for each final certificate for one hundred and sixty acres of land, ten dollars for three hundred and twenty acres, and fifteen dollars for six hundred and forty acres.
7. In the location of lands by States and corporations under grants from Congress for railroads and other purposes, (except for agricultural colleges,) a fee of one dollar for each final location of one hundred and sixty acres; to be paid by the State or corporation making such location.
8. A fee of five dollars per diem for superintending public land sales at their respective offices; and, to each receiver, mileage in going to and returning from depositing the public moneys received by him.
9. A fee of five dollars for filing and acting upon each application for patent or adverse claim filed for mineral lands, to be paid by the respective parties.
10. Registers and receivers are allowed, jointly, at the rate of fifteen cents per hundred words for testimony reduced by them to writing for claimants, in establishing pre-emption and homestead rights.
11. A like fee as provided in the preceding subdivision, when such writing is done in the land office, in establishing claims for mineral lands.
12. Registers and receivers in California, Oregon, Washington, Nevada, Colorado, Idaho, New Mexico, Arizona, Utah, Wyoming, and Montana, are each entitled to collect and receive fifty per centum on the fees and commissions provided for in the first, third, and tenth subdivisions of this section.

Lands not Subject to Pre-emption.

Sec. 2258. The following classes of lands, unless otherwise specially provided for by law, shall not be subject to the rights of pre-emption, to wit:

1. Lands included in any reservation by any treaty, law, or proclamation of the President, for any purpose.
2. Lands included within the limits of any incorporated town, or selected as the sites of a city or town.
3. Lands actually settled and occupied for purposes of trade and business, and not for agriculture.
4. Lands on which are situated any known salines or mines.

Title to Town Lots subject to Mineral Rights.

Sec. 2386. Where mineral veins are possessed, which possession is recognized by local authority, and to the extent so possessed and recognized, the title to town-lots to be acquired shall be subject to such recognized possession and the necessary use thereof; but nothing contained in this section shall be so construed as to recognize any color of title in possessors for mining purposes, as against the United States.

Geological Surveys.

Sec. 2406. There shall be no further geological survey by the Government, unless hereafter authorized by law. The public surveys shall extend over all mineral lands; and all subdividing of surveyed lands into lots less than one hundred and sixty acres may be done by county and local surveyors at the expense of claimants; but nothing in this section contained shall require the survey of waste or useless lands.

Penalty for the False Making, Altering, etc., of any Instrument or Writing, etc., Concerning Lands, etc., in California.

Sec. 2471. Every person who falsely makes, alters, forges, or counterfeits; or causes or procures to be falsely made, altered, forged or counterfeited; or willingly aids and assists in the false making, altering, forging, or counterfeiting any petition, certificate, order, report, decree, concession, denouncement, deed, patent, confirmation, diseño, map, expediente, or part of an expediente, or any title-paper, or evidence of right, title, or claim to lands, mines, or minerals in California, or any instrument of writing whatever in relation to lands or mines or minerals in the State of California, for the purpose of setting up or establishing against the United States any claim, right, or title to lands, mines, or minerals within the State of California, or for the purpose of enabling any person to set up or establish any such claim; and every person who, for such purpose, utters or publishes as true and genuine any such false, forged, altered, or counterfeited petition, certificate, order, report, decree, concession, denouncement, deed, patent, confirmation, diseño, map, expediente or part of an expediente, title-paper, evidence of right, title, or claim to lands or mines or minerals in the State of California, or any instrument of writing whatever in relation to lands or mines or minerals in the State of California, shall be punishable by imprisonment at hard labor not less than three years and not more than ten years, and by a fine of not more than ten thousand dollars.

Penalty for Falsely Dating any Evidence of Title under Mexican Authority, etc., to Lands in California.

Sec. 2472. Every person who makes, or causes or procures to be made, or willingly aids and assists in making any falsely dated petition, certificate, order, report, decree, concession, denouncement, deed, patent, confirmation, diseño, map, expediente or part of an expediente, or any title-paper, or written evidence of right, title, or claim, under Mexican authority, to any lands, mines, or minerals in the State of California, or any instrument of writing in relation to lands or mines or minerals in the State of California, having a false date, or falsely purporting to be made by any Mexican officer or authority prior to the seventh day of July, eighteen hundred and forty-six, for the purpose of setting up or establishing any claim against the United States to lands or mines or minerals within the State of California, or of enabling any person to set up or establish any such claim; and every person who signs his name as governor, secretary, or other public officer acting under Mexican authority, to any instrument of writing falsely purporting to be a grant, concession, or denouncement under Mexican authority, and during its existence in California, of lands, mines, or minerals, or falsely purporting to be an informe, report, record, confirmation, or other proceeding on application for a grant, concession, or denouncement under Mexican authority, during its existence in California, of lands, mines, or minerals, shall be punishable as prescribed in the preceding section.

Penalty for Presenting False Evidences of Title, etc., to Lands in California, and Prosecuting Suits Thereon.

Sec. 2473. Every person who, for the purpose of setting up or establishing any claim against the United States to lands, mines, or minerals within the State of California, presents, or causes or procures to be presented, before any court, judge, commissioner, or commissioner, or other officer of the United States, any false, forged, altered, or counterfeited petition, certificate, order, report, decree, concession, denouncement, deed, patent, diseño, map, expediente or part of an expediente, title-paper, or written evidence of right, title, or claim to lands, mines, or minerals in the State of California, knowing the same to be false, forged, altered, or counterfeited, or any falsely dated petition, certificate, order, report, decree, concession, denouncement, deed, patent, confirmation, diseño, map, expediente, or part of an expediente, title-paper, or written evidence of right, title, or claim to lands, mines, or minerals in California, knowing the same to be falsely dated; and every person who prosecutes in any court of the United States, by appeal or otherwise, any claim against the United States for lands, mines, or minerals in California, which claim to be founded upon, or evidenced by, any petition, certificate, order, report, decree, concession, denouncement, deed, patent, confirmation, diseño, map, expediente, or part of an expediente, title-paper, or written evidence of right, title, or claim, which has been forged, altered, counterfeited, or falsely dated, knowing the same to be forged, altered, counterfeited, or falsely dated, shall be punishable as prescribed in section twenty-four hundred and seventy-one.

TABLE OF THE LEAD MINERALS.

Those of use in Metallurgy for the production of Lead are printed in "CAPITALS," those of rarer occurrence are in "lower case," those so rare as to be interesting only to science are in "italics."

No.	NAME.	HARD- NESS.	SPECIFIC GRAV.	CRYSTALLINE FORM.	PHYSICAL CHARACTER.	CHEMICAL CHARACTER.	COLOR.	STREAK.	COMPOSITION.	PER CT. OF LEAD
1	<i>Albite</i> , syn. Telluride of Lead. Elasmose. Named from the Altai Mountains in Asia, where it was first found.	3. 3.5	8.159	Isometric. Usually massive; rarely in cubes.	Cleavage cubic, luster metallic, sectile, often rich in silver.	In open tube fuses and gives fumes of tellurous acid, forming a white sublimate, which, when strongly heated B. B. fuses into colorless drops; on Ch. in reducing flame colors the flame bluish, fuses to a globule, coating the charcoal near the assay with a metallic ring, outside of which is a brownish coating, entirely volatile, except a trace of silver.	Tin White.		Tellurium 38.3 Lead 61.7	61.7
2	ANGLESITE, syn. Sulphate of Lead. Lead vitriol. Bleivitriol. Sardinian.	2.75 3.	6.12 6.35	Orthorhombic, also massive, granular, and sometimes stalactitic.	Luster highly adamantine. In some specimens resinous and vitreous. In Inyo Co., Cal., occurs laminated and concretionary. Transparent, opaque, conchoidal. Very brittle.	B. B. decrepitates. Fuses in the flame of a candle. On Ch. in O. F. fuses to a clear pearl, which on cooling becomes milk white. R. F. reduces to metallic lead, with effervescence. Fuses with soda, gives beads of lead; the fused soda when placed on bright silver and wet, gives a black stain. Soluble in citrate of ammonia.	White, tinged Yellow, Gray, Green, Blue, nearly Black.	Uncolored.	Sulphuric Acid 28.4 Oxide of Lead 73.6 100.0	68.32.
3	<i>Bismutite</i> , syn. Antimonite of Lead. Bleinerite.	4.	4.60 4.76	Amorphous, reniform, spheroidal, earthy or as an incrustation.	Luster resinous, dull or earthy, opaque. Is of varying composition, and is supposed to result from the decomposition of antimonial ores.	In closed tube gives water. B. B. on Ch. reduced to metallic globules of antimony and lead, coating the Ch. near the assay lemon yellow, beyond which is seen the white coating of antimony.	White, Gray, Brownish, Yellowish.	White, Grayish, Yellowish.	Antimonio acid 31.71 Oxide of Lead 61.98 Water 6.46 99.66	56.97
4	Sulphuret of Antimony and Lead. Embritite.	3.	5.75 6.	In plumose masses, showing in the fracture a crystalline structure. Granular, compact.	Luster metallic.	When heated decrepitates. Fuses very easily. In closed tube gives a faint sublimate. In open tube gives sulphurous fumes and a white sublimate of oxide of antimony. B. B. on Ch. nearly all volatilizes. With soda yields beads of lead.	Bluish Lead Gray, often covered with Yellow spots.		Sulphur 18.9 Antimony 23.1 Lead 58.7 100.0	58.7
5	Caledonite, syn. Cupreous Sulphate-Carbonate of Lead.	2.5-3	6.4	Orthorhombic. Crystals generally small.	Translucent. Fracture uneven, brittle.	B. B. on Ch. easily reduced to the metallic state. Partly soluble in nitric acid, with slight effervescence, leaving residue of sulphate of lead.	Verdigris Green, Bluish Green	Greenish White.	Sulphate of Lead 56.8 Carbonate of " 32.8 " of Copper 11.4 100.00	68.44
6	CERUSITE, syn. Carbonate of Lead. This mineral results from decomposition of galena. The first change being to sulphate by oxidation of the sulphur, then to carbonate by action of carh. of lime	3. 3.5	6.48	Orthorhombic, often found showing the cubic form of galena.	Occurs sometimes granular, massive, compact, rarely fibrous sometimes stalactitic. Luster adamantine, inclining to vitreous or resinous, sometimes pearly, transparent, sub-transparent. Fracture conchoidal, brittle.	In closed tube decrepitates and turns yellow, at a high heat becomes red but changes to yellow again on cooling. B. B. on Ch. fuses easily and yields malleable globules of lead, coating the coal yellow. Dissolves in nitric acid, with effervescence.	White, Gray, Grayish Blk often tinged Green or Blue, by Copper.	Uncolored.	Oxide of Lead 83.5 Carbonic Acid 16.5 100.0	77.51
7	<i>Clausthalite</i> , syn. Selenide of Lead.	2.6-3	7.6-8.3	Isometric.	Occurs commonly in fine granular masses, sometimes foliated, cleavage cubic, luster metallic, opaque, fracture granular and shining, looks much like free grained galena, but bluer.	Decrepitates in a closed tube. In open tube gives odor of selenium, (horse radish) and red sublimate. B. B. on Ch. strong odor of selenium, coating coal near assay gray, with red border, (selenium,) and after longer heating yellow, (lead). When pure volatilizing entirely.	Bluish Lead Gray.	Darker.	Selenium 27.6 Lead 72.4 100.0	72.4
8	<i>Cotunnite</i> , syn. Chloride of Lead.	easily scratched by the nail	5.238	Orthorhombic.	In acicular crystals. Luster adamantine, inclining to silky or pearly.	B. B. on Ch. melts easily, spreads out on the coal and volatilizes, giving a coating which is white, tinged with yellow at the inner edge. In R. F. coating disappears, tingling flame blue, with soda gives beads of lead, if added to a bead of microcosmic salt, saturated with oxide of copper, tinged flame blue, soluble in 22 parts hot water.	White.	Whits.	Chlorine 25.5 Lead 74.5 100.0	74.5
9	CORNEOUS LEAD, syn. Phosgenite of Dana. Chloro-Carbonate of Lead.	2.76-3	6.31	Tetragonal.	Luster adamantine, transparent. Translucent, sectile.	B. B. melts easily to a yellow globule, which on cooling becomes white and crystalline. On Ch. in R. F. gives beads of metallic lead and white coating of chloride of lead. In bead of microcosmic salt, saturated with oxide of copper, gives blue color to flame, (chlorine.) Dissolves with effervescence in nitric acid.	White, Gray, Yellow.	White.	Carbonate of Lead 49 Chloride of Lead 61 100	75.93
10	CROCOITE, syn. Chromate of Lead. Crocoisite.	2.5-3	5.9-6.1	Monoclinic.	Luster adamantine. Vitreous, translucent, sectile.	In closed tube decrepitates and discolors, but recovers its color again on cooling. B. B. fuses easily on Ch., is reduced to metallic lead, with degradation, leaving a green residue of oxide of chromium and coating the Ch. yellow, with microcosmic salt, gives a green bead in both flames, fused with bi-sulphate of potash in a platinum spoon, gives a dark purple mass.	Various shades of Orange Yellow.	Orange Yellow.	Oxide of Lead 68.9 Chromic Acid 31.1 100.0	68.95
11	<i>Dufrenoyite</i> .	3.	5.849 5.862	Orthorhombic.	Luster metallic, opaque, brittle.	Fuses easily, and gives a sublimate of sulphur and arsenic. In an open tube smells of sulphur only, with a sublimate of sulphur in the upper part of the tube and one of arsenic acid below. On Ch. decrepitates, melts, yields fumes of arsenic and a globule of lead, the lead sometimes gives silver on cupellation.	Blackish Lead Gray.	Reddish Brown.	Sulphur 22.10 Arsenic 20.72 Lead 57.18 100.00	57.18
12	GALENA, syn. Sulphuret of Lead.	2.5 2.76	7.25 7.7	Isometric.	Luster metallic. Fracture sub-conchoidal. Frangible. One of the most abundant ores of lead.	In open tube gives sulphurous fumes. B. B. on Ch. fuses, emits sulphurous acid, coats the Ch. yellow, and yields a globule of lead, soluble in nitric acid, often contains silver.	Lead Gray.	Lead Gray.	Sulphur 13.4 Lead 86.6 100.0	86.6
13	Geocronite, syn. Sulphuret of Lead and Antimony. Occurs in Inyo County, Cal. with Galena and Cerusite.	2.3	6.4 6.6	Orthorhombic.	Luster metallic. Fracture uneven.	Decrepitates and fuses easily. In a closed tube gives a faint sublimate of sulphur and sulphide of antimony. In open tube gives fumes of sulphurous acid, and white sublimate of oxide of antimony. B. B. almost entirely volatilizes, coating Ch. white on the outer edge, and dark yellow near the assay, with soda in R. F. gives beads of lead, soluble in hot muriatic acid, fumes smelling of sulphuretted hydrogen. Chloride of lead forms in cooling.	Light Lead Gray.	Light Lead Gray.	Sulphur 16.5 Antimony 16.7 Lead 66.8 100.0	66.8
14	<i>Jamesonite</i> , syn. Heteromorphite. Plumose Antimony. Sulphuret of Lead, Antimony and Iron.	2.3	5.5 5.8	Orthorhombic. Usually in acicular crystals, also amorphous, massive.	Luster resinous. Sub-transparent. Translucent. Laminæ flexible as in gypsum.	Same as Geocronite.			Sulphur 21.1 Lead 49.7 Antimony 32.2 Iron 8.0 100.0	49.7
15	<i>Kobellite</i> , syn. Sulphuret of Lead, Antimony and Bismuth.	Soft.	6.29 6.32		Resembles gray antimony, but brighter in luster. Structure radiated.	B. B. in a closed tube fuses and gives a faint sublimate of sulphur, in open tube sulphurous fumes and sublimate of oxide of antimony. On Ch. fuses, gives coating of lead and antimony. Dissolves in concentrated muriatic acid, giving off at the same time fumes of sulphuretted hydrogen.	Blackish Lead Gray, Steel Gray.	Black.	Sulphur 16.8 Lead 54.4 Bismuth 18.2 Antimony 10.6 100.0	64.4
16	<i>Lanarite</i> , syn. Sulphate and Carbonate of Lead.	2.6	6.3 7	Monoclinic.	Luster of cleavage face pearly, other parts adamantine, inclining to resinous. Transparent, translucent. Laminæ flexible as in gypsum.	B. B. on Ch. easily reduced. Partly dissolves in nitric acid, with effervescence, leaving a residue of sulphate of lead.	Greenish White, Pale Yellow or Gray.	White.	Sulphate of Lead 53.15 Carb. of Lead 46.85 100.00	72.71
17	<i>Leadhillite</i> , syn. Sulpho-Carbonate of Lead.	2.5	6.26 6.44	Orthorhombic.	Luster pearly, resinous, adamantine. Transparent, translucent. Rather sectile.	B. B. intumesces, fuses easily and turns yellow, but white on cooling, easily reduced on Ch. With soda gives reaction of sulphuric acid. Partly soluble in nitric acid, with effervescence, leaving white residue of sulphate of lead.	White, Yellow, Green or Gray.	Uncolored.	Sulphate of Lead 27.45 Carbonate of lead 72.55 100.0	74.93
18	<i>Linarite</i> , syn. Cupreous Sulphate of Lead.	2.5	5.3 5.45	Monoclinic.	Luster vitreous or adamantine. Translucent. Fracture conchoidal. Brittle.	In closed tube gives water and loses its blue color. B. B. on Ch. fuses easily to a pearly head and in reducing flame yields a metallic bead, which if fused with boracic acid gives a bead of copper, with soda and silver gives the reaction of sulphuric acid, decomposed by nitric acid, leaving a white residue of sulphate of lead.	Deep Azure Blue.	Pale Blue.	Sulphate of Lead 74.8 Oxide of Copper 19.7 Water 6.5 100.0	61.08
19	<i>Melanochroite</i> , syn. Phosphokochroite of Dana.	3.5	5.75	Orthorhombic. Crystals usually tabular.	Luster resinous or adamantine. Glimmering, translucent, opaque.	B. B. on Ch. fuses easily to a dark mass, which is crystalline when cold. In R. F. on Ch. yields globules of lead and green oxide of chromium, coating the charcoal at the same time with oxide of lead.	Between Cobaltine and Hyacinth Red.	Brick Red.	Chromic Acid 23.1 Protoxide of Lead 76.9 100.0	71.38
20	<i>Mimeticite</i> , syn. Campylite. Arsenate of Lead. Green Lead ore.	3.5	7.25	Hexagonal.	Luster resinous. Sub-transparent. Translucent.	In closed tube gives a white sublimate of chloride of lead. B. B. fuses easily, and on Ch. gives in R. F. odor of arsenic and is easily reduced to a bead of lead, coating the Ch. first with chloride of lead and afterwards with oxide of lead, and arsenious acid, gives a reaction of chlorine with microcosmic salt, and oxide of copper, soluble in nitric acid.	Pale Orange Yellow, White or colorless.	White.	Arsenate of Lead 90.66 Chloride of Lead 9.34 100.00	62.26
21	<i>Mintum</i> , syn. Red Oxide of Lead. Occurs in several localities in California.	2-3	4.6	Pulverulent. Under microscope, crystalline scales.	Luster faint greasy, dull, opaque.	B. B. yields heads of lead.	Vivid Red.	Orange Yellow.	Lead 90.65 Oxygen 9.34 100.00	90.66
22	<i>Matlockite</i> .	2.5 3.	7.21	Tetragonal crystals, generally tabular.	Transparent, translucent. Luster adamantine, sometimes pearly.	In a closed tube decrepitates and becomes more yellow. B. B. on Ch. fuses easily and is reduced to metallic lead, acid fumes being at the same time given off. A white coating of chloride of lead forms on the coal, the inner edge of which is yellow. Gives a reaction of chlorine, soluble in nitric acid.	Clear Yellowish Greenish.		Chloride of Lead 55.5 Oxide of Lead 44.5 100.0	82.87
23	<i>Mendipite</i> , syn. Chloride of Lead.	2.6 3.	7. 7.1	Orthorhombic. Occurs in fibrous masses, often radiated.	Luster pearly and somewhat adamantine upon cleavage faces. Feebly translucent, opaque.	The same as Matlockite.	White, tinged Yellow Red or Blue	White.	Chloride of Lead 88.4 Oxide of Lead 61.6 100.0	84.77

NO.	NAME.	HARD- NESS.	SP. GR. QUAL.	CRYSTALLINE FORM.	PHYSICAL CHARACTER.	CHEMICAL CHARACTER.	COLOR.	STREAK.	COMPOSITION.	PER CT. OF LEAD
24	Nagayagite, syn. Black Tellurium.	1. 1.5	5.85 7.2	Tetragonal, generally foliated.	Luster metallic. Splendored, opaque, sectile, flexible, in thin laminae.	In open tube gives a sublimate, which when strongly heated, fuses into colorless drops, (tellurium.) B. B. on Ch. forms two coatings, one white and volatile, composed of telluride and sulphate of lead, the other less volatile and of a yellow color, (oxide of lead). If the mineral is heated for some time in the O. F., a globule of gold is left, which, cupelled with lead, assumes a brilliant gold color. Decomposed by nitro-muriatic acid.	Blackish, Lead Gray.	Blackish Lead Gray.	Lead 50.78 Gold 9.11 Silver .53 Copper .99 Sulphur 8.07 Tellurium 30.52 100.00	50.78
25	Plagioclase.	2.5	5.4	Monoclinic, crystals thick, tabular, also massive and granular.	Luster metallic, opaque, brittle.	Same as Geocronite.	Blackish, Lead Gray.		Sulphur 21.3 Antimony 38.2 Lead 40.5 100.0	40.5
26	Massicot, syn. Lead Ochre. Plumbic Ochre. Oxide of Lead.	2.	8. 7.88 9.2	Massive, structure scaly, crystalline, earthy.	Luster dull, opaque, does not soil.	B. B. fuses easily to a yellow glass. On Ch. easily reduced to a metallic lead globule.	Between Sulphur & Orpiment Yellow.	Lighter than color.	Oxygen 7.17 Lead 92.83 100.00	32.83
27	Plumbogummite, syn. Plumbic resinite, Aluminate of Lead.	4-5	6.4	Reniform, globular, botryoidal. In thin crusts, also compact, massive.	Luster resinous or gum-like, translucent, fragile. This rare mineral looks like drops of gum.	In closed tube decrepitates and yields water. B. B. in forceps swells and colors the flame blue, with soda gives a bead of lead. If the assay is first wet with a solution of nitrate of cobalt, and then strongly heated, it becomes blue (alumina), soluble in nitric acid.	Yellowish Gray, Reddish Brown, also, Yellowish White.	Uncolored.	Composition varies. Example as follows: Phosphoric Acid 15.16 Sulphuric Acid .40 Alumina 2.88 Oxide of Lead 70.85 Water 1.24 Chloride of Lead 9.18 99.73	73.12
28	Pyromorphite, syn. Phosphate of Lead.	3.5 4.	6.5 7.1	Hexagonal, often globular, reniform and botryoidal, also fibrous and granular.	Luster resinous, sub-translucent, fragile, fracture sub-conchoidal, uneven, brittle.	In a closed tube gives a white sublimate (chloride of lead). B. B. in forceps fuses easily, coloring flame greenish blue, with soda on Ch. yields metallic lead in a head of microcosmic salt, saturated with oxide of copper colors flame intense blue, (chlorine). Soluble in nitric acid.	Green, Yellow, Brown, sometimes Wax Yellow, to Orange, sometimes Orange Yellow.	White.	Composition varies, sometimes contains lime or arsenic. When pure: Phosphate of Lead 89.27 Chloride of Lead 9.65 Phos & Flu of Lead 1.07 100.00	
29	Stilbite, syn. Scheelite. Tungstate of Lead.	2.75 3.	7.87 8.13	Tetragonal.	Luster resinous, sub-adamantine, faintly translucent.	B. B. decrepitates and easily fuses to a crystalline, lustrous metallic pearl. With soda a lead bead is obtained, with microcosmic salt in O. F. a colorless glass, which in R. F. becomes blue on cooling. Decomposed by nitric acid, leaving a yellow residue of tungstic acid.	Green, Yellowish Gray, Brown, Red.	Uncolored.	Tungstic Acid 51.60 Oxide of Lead 49.00 100.00	45.57
30	Vanadinite, syn. Vanadate of Lead.	2.75	6.55 7.23	Hexagonal, usually in implanted globules or locust-tails.	Luster of surface of fracture resinous, faintly translucent, opaque, fracture uneven or flat, conchoidal, brittle.	In closed tube decrepitates and yields a faint white sublimate. B. B. fuses easily, on Ch. to a black lustrous mass, which in R. F. yields a metallic lead and a coating of chloride of lead. After perfectly oxidizing the lead in O. F. the black residue gives with microcosmic salt an emerald green bead, which in R. F. becomes bright yellow. In O. F. gives chlorine reaction. Fused with three parts of bisulphate of potash, forms a clear yellow mass, which on cooling reddens, becoming finally a pomegranate yellow color. Decomposed by muriatic acid. If nitric acid be dropped on the crystals they become first a deep red, and when dissolved, yellow.	Light Brownish, Yellowish, Straw Yellow, Reddish Brown.	White or Yellowish.	Vanadate of lead 90.3 Chloride of Lead 9.7 100.00	68.61
31	Vanadinite, syn. Chromate of Lead and Copper.	2.5 3.	5.5 5.78	Monoclinic. Crystals usually minute and irregularly aggregated, also reniform, botryoidal, granular and amorphous.	Luster adamantine to resinous, transparent, fracture conchoidal, brittle.	B. B. on Ch. decrepitates and easily fuses to a gray sub-metallic globule, yielding at the same time globules of metal. With borax or microcosmic salt yields a green transparent glass in the outer flame, which in the inner, after cooling, is red or black, according to the quantity of the mineral used. Red color more distinct if a little tin is added to the bead. Partly soluble in nitric acid.	Greenish Brown, Apple Green, Siskin Ore'n Olive Green ochre brown nearly black.	Greenish Brownish.	Vanadate of lead 90.3 Oxide of Copper 10.4 Chromic Acid 27.7 100.0	66.55
32	Wulfenite, syn. Molybdate of Lead. Yellow Lead Spar. This is not a rare mineral on the Pacific Coast, but is not found in sufficient quantity to be of economic value.	2.75 3	5.93 7.01	Tetragonal.	Luster resinous or adamantine, transparent, fracture conchoidal, brittle.	B. B. decrepitates and easily fuses. With borax in O. F. gives a colorless glass. In R. F. it becomes opaque, black or dirty green, with black flocks. With microcosmic salt in O. F. gives a yellowish green glass, which in R. F. becomes green. With soda on Ch. gives metallic lead. Decomposed in evaporation with muriatic acid, forming molybdic acid and chloride of lead, on moistening the residue with water and adding metallic zinc, an intense blue color appears, which does not fade when diluted with water.	White.	White.	Oxide of Lead 35.5 Oxide of Lead 61.5 100.0	56.65
33	Zinkenite, syn. Sulphide of Lead and Antimony.	3. 3.5	5.30 5.35	Orthorhombic, sometimes columnar, fibrous or massive.	Luster metallic, opaque, fracture slightly uneven.	Decrepitates and fuses very easily. In closed tube gives faint sublimate of sulphur and sulphide of antimony. In open tube sulphurous fumes and white sublimate of oxide of antimony. B. B. on Ch. is almost entirely volatilized, giving a coating which on the outer edges is white and near the assay dark yellow. With soda in R. F. yields globules of lead. Soluble in hot muriatic acid, sulphuretted hydrogen being given off, and chloride of lead separating on cooling.	Steel Gray.	Steel Gray.	Sulphur 22.1 Antimony 42.6 Lead 35.3 100.0	35.1

Lead.

[Written for the Press by HENRY G. HANES.]

Metallic lead has a bluish gray color. It is usually tarnished, in which case it has no luster, but when freshly cut shows a surface highly metallic and brilliant. It is a soft metal, very malleable, easily fusible, and volatile at a white heat. It is scarcely acted on by hydrochloric acid or dilute sulphuric acid; but moderately dilute nitric acid dissolves it, more readily if heat is applied.

The presence of lead in any substance containing it may with certainty and ease be determined by heating the sample on a piece of well burned willow charcoal, in one portion of which—nearest the flame—a small cavity or depression has been made, in which the assay may be placed, a little carbonate of soda added and the flame of an oil lamp or large candle turned upon it by means of the mouth blow-pipe. The direction of the flame at first should be downwards until the assay begins to melt, after which it should be blown softly and nearly horizontally across the charcoal. If lead is present in the assay a coating will form on the charcoal which is lemon yellow when hot, and sulphur yellow when cold. Other volatile substances which may be present will also form coatings, but they will be distinct, and at distances more remote from the assay, nor will they be the same color. Zinc, like lead, gives a yellow coating, which to the inexperienced might lead to mistakes, but if the charcoal is allowed to cool the zinc coating will become white, by which reaction it may be distinguished.

The following are the reagents used in the determination of lead in the wet way, and the reactions which occur:

Hydro-sulphuric acid or sulphide of ammonium added to solutions of lead salts gives black precipitates of sulphide of lead which are not soluble in cold dilute acids, alkalies, alkaline sulphides or cyanide of potassium, but the precipitate may be decomposed by boiling nitric acid. The acid must be dilute or a part of the lead will be changed to the sulphate and remain insoluble.

Soda, potassa and ammonia throw down basic salts of lead in the form of white precipitates which are insoluble in ammonia. The

exception is solution of acetate of lead, from which pure ammonia (free from carbonate) does not immediately produce a precipitate, a soluble triacetate of lead being formed.

Carbonate of soda produces a white precipitate of basic carbonate of lead, when added in solution to the solution of any lead salt. This precipitate is not soluble in excess of the precipitant nor in cyanide of potassium.

Hydrochloric acid or the soluble chlorides produces in solutions of the lead salts, if concentrated, a heavy precipitate of chloride of lead, which is soluble in a large quantity of warm water.

Sulphuric acid and sulphates throw down from lead solutions a heavy precipitate of sulphate of lead, which is nearly insoluble in water and dilute acids, but dissolves readily in solution of citrate of ammonia.

Chromate of potassa when added to solution containing lead throws down a beautiful yellow precipitate of chromate of lead, which dissolves in potassa, but which is nearly insoluble in nitric acid.

It should be understood that the above reagents are in solution, and are to be added in every case to solutions of substances containing lead.

Lead occurs in nature in a variety of forms, but most of the metal furnished to commerce is from galena or sulphuretted lead. Native lead is reported as occurring in globules at Alston Moor, and at the mine near Caribagua, Spain, but never in sufficient quantity to work, or even to furnish specimens for the cabinet of the mineralogist.

Galena, the most abundant ore of lead, has a metallic luster. Its color and streak are pure lead gray. When broken it is still cubic in form, even when reduced to the finest powder. It always contains silver and sometimes selenium, zinc, cadmium, manganese, gold, antimony, copper and iron. Even platinum is said to be found in galena in France.

It is a mistake to suppose that any external appearance indicates the quantity of silver in a sample of galena.

There is a variety of galena which is called sparsenphuretted lead. The excess of sulphur results from the decomposition of a portion of the galena, setting the sulphur free.

There are several minerals which resemble galena, and may easily be mistaken for it. The most common is micaceous iron, a variety of hematite. The resemblance of this mineral to galena is sometimes so striking as to deceive the inexperienced. It may, however, be distin-

guished by the following tests: When heated on charcoal it gives off no odor of sulphur, nor can it be fused before the blow-pipe. No metallic beads are formed when carbonate of soda is added. After strong heating it becomes red, and on cooling is found to be attractable by the magnet.

Galena in Missouri and Illinois has been extensively worked. The largest deposits in the world are in the Western States, and that ore is there found associated with limestone, blende, carbonate and sulphate of lead, pyrites, and often an ore of copper and cobalt.

The lead region of Wisconsin comprises sixty-two townships, eight in Iowa, ten in Illinois, being eighty-seven miles in diameter, from east to west, and fifty-four miles from north to south. Throughout this region there is scarcely a square mile in which traces of lead may not be found. From a single spot not exceeding fifty yards square, three million pounds of ore have been raised, and in one of the townships two men have raised 16,000 pounds in a day. The mines of the upper Mississippi afford about 760,000 pigs annually, and those of Missouri about 150,000 pigs.

In 1874 the production of lead in California more than doubled, while in the same year that of England decreased 17,000 tons.

For making white lead Eastern corrodors prefer the Missouri lead to any other.

To give the reader some idea of the production of lead in the United States, the following statistics for the year 1874 have been compiled:

TONS.	TONS.
Missouri.....15,000	Chicago.....2,200
California.....8,000	
New York.....	46,500
Newark.....	6,500
Philadelphia.....	
Iowa.....	Imported.....18,000
Illinois.....5,500	U. S. Sales.....4,000
Wisconsin.....	
Omaha.....5,800	
Salt Lake.....3,500	68,500

In 1874 the Union Pacific railroad carried East 3,500 tons refined lead and 15,000 tons blende, by which is meant lead carrying more or less of the precious metals.

Explanation of the Accompanying Table.

Abbreviations: syn.—synonym; all the names following this abbreviation allude to the same mineral, being names given by different authors; B. B.—before the blow-pipe; Ch.—charcoal; O. F.—oxidizing flame; R. F.—reducing flame. This table gives the reactions of pure minerals. What is meant by a mineral is an inorganic substance, every portion of which has the same chemical composition. Ores may be pure miner-

als, or may be aggregations of minerals. The definition of "ore," being any mineral substance which is mined and worked for the production of one or more metals, no matter what its constituents may be. Thus a mixture of gangue with one or more lead minerals interspersed through it, would be called "lead ore." If it contained sufficient silver or minerals containing silver, to be more valuable for the production of that metal, it would be called "silver ore," although it contain lead. This being understood an example will fully illustrate the use of the table.

The substance (which must be as found in nature), is tested for lead in the manner before described. If it is found to contain lead, it must be examined carefully to see if it is uniform, and not a mixture. The eye alone cannot be trusted, a fragment must be broken from the specimen and examined by a good microscope, a portion must then be pulverized and again magnified and examined. If found to be homogeneous, the table may be consulted. Suppose the color to be orange yellow; by looking in the column devoted to the color of minerals, it will be found that, although a number of minerals are yellowish, yet only four are found to be orange yellow. It may be explained here that where several colors are mentioned, following each other, it should be understood that the mineral has been found possessing these colors, of course in different specimens.

The orange yellow minerals are massicot, pyromorphite, wulfenite, and mimette. With the almost certainty that the mineral is one of these, the columns headed Physical Character and Chemical Character may be consulted, and a few experiments will lead to its identification.

By "streak" is meant the color of the mark made by some scratching instrument; for example, a piece of slate is black, but if a scratch is made on it with a hard substance, the streak will be white. In many minerals the color and streak are the same.

In the column headed "Physical Character," descriptive words follow each other in most cases as, "transparent," "opaque." This means that the mineral is sometimes transparent, while in other specimens it is opaque.

Assays in the Dry and Wet Way.

The assay of lead in the dry way is never absolutely correct, for several reasons. 1st. From the volatile nature of all lead compounds, making the result too small. 2d. From the tendency of other metals to alloy with the lead, as gold, silver, copper, antimony, etc., giving

results too great. 3d. When sulphur is present some of the lead sulphide is liable to form a slag or "matte" without being decomposed, and thus to escape determination. Notwithstanding these sources of error, yet such assays approximate to the working of the ores in a large way, and when carefully made and verified by proofs, are generally accepted as correct.

The wet assay, although attended with some difficulties, is by far the most accurate and reliable.

Before lead ores are prepared for assay in the dry way, regard must be had to their chemical character. It is best to divide them into classes, each of which must be treated by a different process.

Class 1. Ores containing either sulphur or selenium, or both.

Example: Galena, clausthalite, lead matte or regulus, furnace products, etc.

Class 2. Ores containing oxide of lead combined with various mineral acids, sulphuric acid, chromic acid, phosphoric acid, arsenic acid, carbonic acid, etc.

Example: Anglesite, cerussite, pyromorphite, etc.

Class 3. Metallic lead alloyed with other metals.

Distinguishing Minerals.

It is easy to distinguish to which class a specimen of lead mineral belongs. It has already been shown how to test a mineral for lead. After doing so observe if it has a metallic luster and a certain degree of malleability, showing a bright metallic streak when freshly cut. It will not be difficult to determine if it is an alloy by these tests. If so, it evidently belongs to class 3. If not, fuse a small piece with carbonate of soda on charcoal; when cold remove the slaggy mass and place it on a clean silver coin and add a few drops of water. If the silver is blackened so that the stain cannot be washed off with water, the mineral contains sulphur or selenium in some form. Before testing for sulphur with carbonate of soda and silver, the purity of the soda must be proved by wetting a small portion of it and laying it on the bright silver. If pure, no blackening will appear. If the reverse should be the case, the reagent is worthless and should not be used; such soda can be purified, but the process cannot be explained here. As sulphate of lead belonging to class 2 gives the same reaction, a second piece of the ore must be placed in a clean glass tube, four or five inches long, open at both ends, and heated while holding the tube in an inclined position. If sulphur is present as a sulphide, or if selenium is present, the smell can easily be recognized if the upper end of the tube is held near the nose. If sulphur, the smell of burning sulphur will be observed. If selenium, that of rotten horseradish will be distinguished. If no sulphur is detected (class 1) the substance belongs to class 2.

Having decided to which class the substance belongs, it may be pulverized, passed through a sixty mesh sieve and thoroughly mixed. If in a metallic state (class 3) a portion may be cut off with a cold chisel, rolled out thin and out into shreds with a pair of scissors, or may be drilled and the borings taken for assay.

Assaying Average Samples.

It is often required to sample a number of lead bars, and to make an assay representing the average of them all. The best method of proceeding is to drill a hole into each bar deep enough to obtain borings sufficient for duplicate assays. To insure a correct result it is best to take a portion from several parts of each bar; the samples should be numbered or marked to correspond with a similar mark or number on the bar. The bars are then weighed. If of uniform weight, equal portions by weight of the borings are thoroughly mixed and a portion of the mixture assayed according to the directions to follow. If of unequal weights, the same weight in grammes of each, corresponding to the weight of the bar in pounds, are mixed for assay. If extreme accuracy is desired, the result may be verified by making single assays of each sample, and taking the mean of the result.

Assaying First-Class Ores.

There are a number of methods of assaying ores of the first class, each one having its own advocates.

1st. *Fusion with carbonate of potash.* In case the ore contains but little sulphurets other than those of lead, but more or less of earthy matter.

2d. *Fusion with black flux.* (Black flux is made by mixing two parts of argol and one part nitre in an iron vessel, setting the mixture on fire and allowing it to burn).

3d. *Fusion with or without fluxes in wrought iron crucibles.*

4th. *Fusion with carbonate of soda and nitre.*

5th. *Fusion in clay crucibles with fluxes and metallic iron.*

For all practical purposes the last mentioned is the best, and the modification proposed by Mitchell is simple and accurate.

For the assay, ordinary sand crucibles, triangular at the top, are used (called Hessian crucibles). The most convenient size is four and one-half inches high. It is recommended to smear them inside with plumbago, but I have never found this precaution necessary.

Twenty grammes of the ore are weighed out and placed in the crucible, five grammes of argol, twenty grammes carbonate of soda, five grammes carbonate of potash, ten grammes of pulverized borax are added, and the whole thoroughly mixed with a spoon or spatula; three large nails are then placed head downward, one in each corner. They must be

pushed down to the bottom of the crucible, and the crucible tapped on the mixing table when the mixed contents form a level surface around the nails. The surface of the assay must then be covered with common salt (twenty grammes will be about the amount required) and the crucible again tapped on the table to settle all down evenly and compactly; ten grammes of borax in lumps is put loosely on top, and the crucible is ready for the fire; a second crucible must be prepared exactly like the first for the duplicate assay. *No single assay should be trusted.*

Precautions in Fusing.

I have given the quantities of the fluxes by weight, but after practice the assayer will be able to mix the assays by using a spoon about the size of an ordinary tablespoon and judging of the quantities by his eye. A little more or less of the fluxes does not materially matter. He will soon be able to judge of the quantity required and from the appearance of his crucible in the fire know what to add to make it fuse freely. Any addition that may be required may be made by wrapping the dry flux in a piece of paper and dropping it into the hot crucible with the cupel tongs. There are certain precautions to be observed in fusing the assay. Too hot a fire is apt to volatilize a portion of the lead, causing loss, while too slow a fire does not effect the perfect fusion of the assay and the globules which form cannot gravitate to the bottom, there to form a single prill or button. It is best to commence with a good fire which has burnt rather low, but in a hot furnace. The crucibles are placed on the hot coals and fresh fuel built up around them by putting in charcoal or coke as the case may be, in lumps singly with the cupel tongs. The dampers and doors of the furnace are then arranged so as to produce the best draft. When the fresh fuel is igniting the fusion progresses slowly. The furnace soon becomes very hot, which is the exact condition required for the finishing of the fusion. The crucibles which are at first covered must toward the end be uncovered and the covers need not again be replaced. When the assays are in the most perfect state of fusion the crucibles may be removed one at a time with suitable crucible tongs. As soon as removed from the furnace a rotary motion should be given to them (soon learned by practice). This motion causes the fluid slag to sweep round the inside of the crucible, washing down to the center any stray globules. The nails are then removed by taking them out one by one with the cupel tongs, washing off any adhering lead by rinsing them in the liquid slag. When the nails are removed the crucible is tapped against the brick floor or against any hard non-inflammable substance, and set in some convenient and safe place to cool.

When cold the crucible must be broken on an anvil and the button of lead hammered into a cube and weighed. Both buttons should weigh alike or nearly so.

Calculating Percentage.

The calculation of percentage is simple. Suppose the twenty grammes of ore contained 9.462 grammes of lead; it is clear that 100 grammes of lead would contain five times as much. The number of parts in one hundred being the percentage, the result would be as follows:
 $9.462 \times 5 = 47.31$ per cent.

Antimonial Galena.

Galena often contains antimony in the form of sulphuret, in which case the method described above would not give correct results. The presence of antimony may be proved by reducing a bead with carbonate of soda on charcoal. If the ore contains antimony white fumes will be given off and a white coating on the charcoal will be seen more distant from the assay than the yellow coating of lead; or the finely pulverized ore may be shaken up with a solution of caustic potash, the solution filtered and acidulated with a strong acid; a yellow precipitate of sulphide of antimony will fall if the ore contains sulphuret of antimony.

Antimonial galenas may be treated in such a way as to obtain the lead pure, or all the antimony combined with the lead.

To obtain the lead only, the assay must be mixed with four times its weight of carbonate of soda covered with salt, lumps of borax placed on top, and treated in the furnace exactly as described in the first operation. No nails should be added.

To obtain the lead and antimony together mix the assay with equal parts by weight of cyanide of potassium and carbonate of soda.

It is sometimes found to be economical and not objectionable to pour the assay into a small concave mould instead of breaking the crucible, which may be used for subsequent assays. This should never be done unless in cases where many assays are to be made of ore from the same mine.

Wet Assays of First-Class Ores.

Assays of the ores of the first class may be made by the humid method as follows:

Pulverize the ore very finely, weigh ten grammes carefully, boil in a flask with twenty C.C. of strong nitric acid on a sand bath until the ore is completely decomposed and no more red fumes are given off. Pour out carefully into an evaporating dish and evaporate to complete dryness. Care must be taken in this operation that no violent spitting or decrepitation of the assay takes place by which any part may be lost. When the dry mass is cold it must be boiled with a strong solution of carbonate of soda. It should then be poured on a filter and well washed with distilled water. Dilute acetic acid is then cautiously ad-

ded, by which it is dissolved and passes through the filter into a clean beaker which must be placed to receive it. When the solution is complete every portion of the solution must be washed from the filter with distilled water. Earthy matters remain in the filter.

If dilute sulphuric acid is now added to the contents of the beaker the whole of the lead is thrown down as sulphate, which may be thrown on a weighed filter and thoroughly washed with distilled water and alcohol, dried at the temperature of 212 degrees Fahr., and weighed. The weight of the filter must be deducted from the weight obtained. The sulphate of lead contains 68.28 per cent. of metallic lead. There are some sources of error to be avoided in this operation. If the precipitate is not thoroughly dried in the filter correct results will not be obtained, neither will it do to heat the filter so hot as to char or partly burn it. It is better to take two filters made of the same paper, fold them together while cutting them, then separate them, place one in each pan of a balance, and carefully trim the heaviest with a pair of scissors until they weigh alike; fold them together again, put them in the funnel together, wash the precipitate on them, dry together in a steam bath, then separate them, place the one with the precipitate in one pan of the balance and the other in the other pan; the difference will be the weight of the precipitate. There is a method common with chemists of burning the filter and incinerating the ashes with the precipitate in a platinum crucible, at a red heat, but the conveniences are not found in ordinary assay offices. The details may be found in any work on quantitative analysis. With proper care correct results may be obtained by drying the precipitate on the filter. In the process given above the following reactions occur:

1st. The nitric acid attacks the ore and oxidizes both the sulphur and the lead, forming sulphate of lead.

2d. By evaporating to dryness, the excess of nitric acid is drawn off, but leaving some nitrate of lead mixed with the sulphate.

3d. The carbonate of soda decomposes the sulphate of lead, forming carbonate of lead and soluble sulphate of soda, which is washed out as directed with distilled water.

4th. The dilute acetic acid poured on the filter decomposes the carbonate of lead and forms acetate of lead, which, being soluble, passes through the filter, leaving insoluble matter, if there be any, in the filter.

5th. Sulphuric acid, being a stronger acid than acetic, combines with the lead, giving now the pure sulphate.

The calculation of the assay is made as follows:

It has been shown that sulphate of lead contains 68.28 per cent. of metallic lead; it is clear that we must find that per cent. of the sulphate of lead we obtain, which will be the amount of lead in ten grammes of the ore. Suppose we obtain 7.46 grammes of sulphate of lead in the ten grammes of ore, then $7.46 \times .6828 = 5.09$ metallic lead. Ten grammes yielding this (5.09), it is clear that 100 grammes would yield ten times as much, which is the percentage. The result would then be as follows: Lead, 50.9 per cent.

Assays of Class Two.

The assay of substances belonging to class 2 is very simple. Twenty grammes of the ore is weighed out as in the case of assay of first class, ten grammes of red argol and thirty grammes of carbonate of soda are well mixed in the crucible, the whole covered with a layer of salt and tapped on the mixing table to settle all down. Put the crucible into an increasing fire and keep at low red heat for quarter of an hour. Then increase the heat until the contents of the crucible flow freely, tap gently and set it aside to cool, break the crucible, hammer the button into a cube and weigh. If arsenic or lead or sulphide of lead are present see nails.

The humid assay of this class is made by heating ten grammes of the substance to redness, and afterwards holding it in a flask with dilute nitric acid (one part of acid to one-two of water by volume), when the action ceases pour the contents of the flask into an evaporating dish and cautiously evaporate to dryness, allow the dry mass to cool, add dilute nitric acid, gently warm for an hour, add water, boil and filter. The solution now contains all the lead as nitrate, the precipitative washing and weighing may now be conducted as directed in humid assays of ores of the first class.

Class Three—Alloys of Lead with Other Metals.

Alloys must be boiled with dilute pure nitric acid, the solution decanted from the precipitate, which must be washed with water and the washings added to the solution, which must then be filtered.

The solution may contain all the other metals likely to be present in alloys, except gold, platinum, antimony and tin.

The solution (which should never be too dilute), must be mixed with dilute sulphuric acid slightly in excess. (This may be explained by stating that "excess" means the slightest quantity of reagent in excess of what is required to precipitate all of the lead.) The dilute acid should be added slowly, and the precipitate allowed to settle before further addition is made. When the sulphate of lead has all precipitated, double the volume of alcohol is added, and the whole set aside for a few hours to settle, after which it is decanted and washed into a small filter, washed with alcohol and dried on a water bath, or in the sun. When the precipitate on the filter is perfectly dry, a clean piece of writing paper is spread on a table and a small

clean porcelain cup set in the center of it. The precipitate must then be carefully detached from the filter, and transferred to the cup. The dry filter is then held in a pair of small pliers over the cup, and burned by applying a match or candle flame; the ashes which fall on the paper must be brushed into the cup. The cup may then be placed on a piece of wire gauze placed on the ring of a retort-stand and heated from below with a spirit lamp to a red heat. When cold, the cup and contents are weighed and the tare of the porcelain cup deducted, the remaining weight will be that of the sulphate of lead obtained from the alloy.

The weight of the alloy taken for assay and the calculation are the same as in the last example.

When great accuracy is not required the use of alcohol may be dispensed with, but more excess of sulphuric acid must be used for precipitation and the washing water must contain some dilute sulphuric acid.

The Manufacture of Solder.

The alloys of metals are frequently more useful than either of the substances used in combination, and often exceed them in respect to some quality which is of great importance. Brass is much more used than zinc, and the alloys of lead are fully as valuable as the metal uncombined. The union of lead with tin is of immense value in the arts. It enables rough surfaces to be joined in a way that could not otherwise be done, except at immense expense. The solder melts at a low temperature, and can be applied with the utmost ease.

The most common compound of these metals is 70 parts of tin to 130 parts of lead, and is generally known as No. 1, or hard solder. Other substances are frequently incorporated, such as bismuth, antimony, and even copper. This is done for the purpose of increasing the hardness, fusibility or tenacity, and each firm has its own combination for this purpose. Made, as we have stated, it is the alloy generally used for joining articles of tin, fusing at 360 deg. Fahrenheit.

But for plumbers it is necessary to use another article which shall remain firm and solid when exposed to heat. A pan or basin of tin must frequently be exposed to a fire, and one of the values of the compound we have mentioned is its comparative resistance to heat. But lead pipe is never exposed to any such danger, although it frequently needs to be repaired, as its contraction and elongation in consequence of temperature, the attacks of mice and rats, and the thousand and one disasters to which it is subject, requires it, and that with something which is not of high enough temperature above its own to melt the pipe, as would be the case with either zinc, copper or iron.

Plumbers' solder answers this purpose, and is, beside, cheaper than the harder compound. It fuses at a point much less than the preceding formula, and less than either of the metals when treated separately. It unites readily with a clean surface of either lead or zinc, and remains for a short time in a semi-fluid state, enabling the manipulator, by the aid of the cloth holder or pad, to mold it in any desired shape. When used by plumbers to join the portions of lead pipe, this is commonly termed a wipe joint. These two metals are not alone in making a fusible compound. There is one alloy known to the art from which teaspoons can be made, bearing much the appearance of silver when new, but so easily acted upon that the stirring of the fluid will cause the bowl and handle to melt and fall to the bottom of the cup.

The manufacture of solder has been for years an important industry. Some of our largest houses in the metal trade make their own, but the greatest bulk is manufactured by special houses in the trade.—*Sheet Iron Builder.*

GALVANIZED SHEET IRON was introduced in 1837 by Mr. H. W. Crawford, who applied it chiefly to sheets of corrugated iron, or sheet iron bent by a peculiar process into alternate semi-circular elevations and depressions, and this soon became extensively employed for roofing purposes, especially for railway sheds, which were then beginning to be in great request. For cornices, galvanized iron has almost entirely superseded both wood and stone, the immense weight of stone necessary to give the required projection being one of the principal objections to its use, while the danger to wood from fire, besides its great cost, precludes its employment as a cheap, durable and substantial material. Besides, the absorption of moisture to which our freestone is liable causes it to scale after damp and frosty weather, while in case of fire it is liable to split and fly to pieces. Its cost, moreover, is about four times as much as that of galvanized iron, while the latter will look better and wear out any quality of stone that may be employed.—*Building Association Journal.*

GREATEST POWER OF A HORSE.—A horse can exert his greatest strength in drawing in a straight line, being equal to twenty-seven men in this direction. This is seen in the way they draw loads on the road. In a circle a horse exerts his greatest strength, with a diameter of forty feet. Reduce the diameter of the circle one-half, and you reduce the power of the horse two-fifths.

TO GILD WITH GOLD.—By rubbing metallic surfaces with soda amalgam, and pouring on a solution of chloride of gold, gold is taken up by the amalgam; and it is only necessary to drive off the mercury by heat, to obtain a gilded surface that will bear polishing.

SAN FRANCISCO.

Mining and Scientific Press,

A VALUABLE WEEKLY FOR

Miners, Mechanics and Manufacturers
on the Pacific Coast.

Volume XXX of this first-class, standard journal commenced with the year 1875. Its proprietors, having the successful experience of ten years publication of the Press, have no hesitation in saying that for the ensuing year the paper shall, in keeping with the times, reach a higher mark of merit than ever before. With our own printing press, folding machine,

Able Editors, Correspondents,

And skilled workmen in different departments of our now extensive and growing establishment, we mean to print a journal throughout the year, which all citizens, whether patrons or not, may be proud of seeing published and supported on this side of the continent.

No kindred journal in America furnishes more real

Fresh, Novel, Interesting Information

In its volumes than the MINING AND SCIENTIFIC PRESS. We have the

Largest Mining Field in the World

To report from. It embraces the largest variety of mines and mining; methods of working; and more numerous wonderful discoveries than any other section of the globe. It is the birth place of many of the

Latest and Best Inventions in Gold,
Silver and Labor Saving,

With brief, reliable, well chosen and prepared editorials; varied and condensed correspondence and selections; tables and statistics arranged for ready reference,

Superior Illustrations,

Of local and general interest to its readers, it forms a weekly journal of individual character and unrivalled worth to its intelligent and industrial Patrons at home and abroad. It is the

Leading Mining Journal of America,

And in its practical, interesting and substantial make up, it is unrivalled by any mining or mechanical journal in the world.

Home Manufactures and Home Inven-
tions

Will be constantly encouraged. Both help to build up the brain and material wealth of the country. They are kindred to our individual enterprise. Our interests are mutual with all home artisans and producers. Where on the face of the globe do INVENTORS and MANUFACTURERS either NEED or DESERVE more encouragement?

Its Value to the Community,

In disseminating important information; dissipating false notions; checking expensive follies; instigating important enterprises; by wise counsel and scientific direction, enriching the rewards of honest labor, we are annually saving and adding

Millions of Dollars

To the products of our country. The PRESS has already

A Large Circulation,

And is deserving of more universal patronage from those whose interests it specially represents. This sparsely populated portion of the Union is a difficult one for publishers to present the claim of their journal in to all who should subscribe. In these times of seemingly cheap (but largely, trashy and worthless) journalism, it is desirable and proper that those who know the real merits of a faithful journal should

Speak and Act in its Favor.

We shall not spare our efforts to make sound and improved issues, maintaining constantly the rights of all, and forwarding the material and intellectual rights of our patrons, and of our sturdy, progressive community.

Necessarily, scientific and mining publications generally are costly and high priced, but considering the size, character and location of our publication, our rates are favorable for so valuable a print.

We invite correspondence from all sections. Subscriptions, payable in advance, \$4 a year Single copies, postpaid, 10 cents.

Address, DEWEY & CO.
PUBLISHERS, No. 224 Sansome St., S. F.

A Good Binder for \$1.50.

Subscribers or this journal can obtain our Patent Elastic Newspaper File Holder and Binder for \$1.50—containing full title of the paper on the cover. It preserves the papers completely and in such shape that they may be quickly fastened and retained in book form at the end of the volume, and the binder (which is very durable) used continuously for subsequent volumes. For sale, 25 cts. extra. It can be used for Harper's Weekly and other papers of similar size. If not entered, please, purchasers may return them within 30 days. Just the thing for libraries and reading rooms, and all who wish to file the PRESS.

SEND FOR FREE CIRCULAR OF INFORMATION FOR INVENTORS.

The Pacific Rural Press,
AN ILLUSTRATED
AGRICULTURAL HOME JOURNAL.

Among other Reasons for Subscribing are the

Following:

Because it is a permanent, first-class, conscientious able, and well conducted journal.

Because it is the largest and best agricultural weekly west of the Rocky Mountains.

That Patrons may be fully posted on the progress of the Order in this and other fields.

That more farmers' wives and children in their isolated homes may be cheered by its weekly visits, laden with its pleasing, yet moral reading, and sound instruction.

That a more extended interchange of views and opinions may be had among farmers, upon all the great questions touching their mutual interests and progress.

That the agricultural resources of the Pacific States may be more wisely, speedily and thoroughly developed by an open and free discussion in our columns.

That all the honest industries of our State may be advanced in connection with that of agriculture, our columns being ever open to the discussion of the merits of all progressive improvements.

That the RURAL, after having been read and pondered over by the home circle, can be laid away for future useful reference, or forwarded to the old Eastern fire-side of the Atlantic border, in aid of an increasing immigration to our sunny clime.

PATRONS will please subscribe of their Secretary and aid in getting up or increasing the club in their Grange, and thereby receive the benefit of club rates.

Send for free sample copies and further information. Secretaries, Lecturers and other Patrons are cordially invited to correspond for our columns, for the good of the order and their local interests.

DEWEY & CO., Publishers,

San Francisco, January, 1875.

Hints about Advertising.

If you have goods to sell farmers, how much better will it pay you to advertise in a farming paper, closely read by 16,000 intelligent farmers, than in miscellaneous daily or weekly journals with 30,000 readers, comprising only 2,000 farmers. A mining journal in California with 15,000 readers reaches more intelligent miners than any other 10 papers in the Union.

Purchasers are more likely to look for information in the advertising columns of a paper devoted to their special interests, than elsewhere, when ready to buy. Some will not read advertisements upon any other occasion, but seek the best paper when wanted.

If you happen to be the only advertiser in your line of business in a paper, all the better. But if several firms advertise the same, your own judgment will question whether you can best afford to go unrepresented.

Weekly journals are read most leisurely and carefully, and at a time when the subscriber is most favorably inclined to examine advertisements. The newspaper most specially representing your particular branch of industry is usually best entitled to your patronage, and the most profitable medium you can employ.

An advertisement in an honest and handsome sheet is favorable to the reputation of the advertiser. The readers of the Press are a superior and industrious class, who are able to purchase and who seek to patronize the best and fairest dealing tradesmen.

Advertising in cheap priced mediums (of limited circulation) is like buying goods at retail when you could as well take them at wholesale.

Information imparted to a list of superior and intelligent, and active, and industrious readers (naturally looked up to by others for information), is seed sown in good soil for the advertiser.

Fame and fortune are gained, nine times in ten, by liberal and judicious advertising.

UNITED STATES
Mineral Land Laws, Revised Statutes,
And Instructions and Forms Under the
Same.

We have just issued a pamphlet containing the general mineral land laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870 Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Register's Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or Absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U.S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of MINING AND SCIENTIFIC PRESS, S. F.

N. B.—We have also added to the above publication, the REVISED STATUTES OF THE UNITED STATES, so far as relates to Mining Laws.

A COMPLIMENT.

PLAINSBORO, MERCER CO. CAL., June 22, 1874.
DEWEY & CO.—Gentlemen: I herewith tender my grateful acknowledgments for the energy, promptness and efficiency which you have displayed in procuring my patent.

Although you were entire strangers to me when I first communicated with you, I soon felt satisfied you were gentlemen of integrity, and shall always be happy to represent you as such. Very truly yours,

H. W. BUCKER, M. D.

SANTA CLARA, CAL., April 6th, 1875.
MESSRS. DEWEY & CO.—Gentlemen: We have just received Patent No. 160,535, for J. T. Watkins & Co's Mammoth Road Grader, which was patented through your Agency. It is the nearest and best that we have ever received. We feel proud of it and thankful to you for the care and attention that you have given it, and when we have anything to do in that line of business we will surely give you a call. Very respectfully,

J. T. WATKINS & CO.

TEACREEK, CAL., July 10, 1874.
MESSRS. DEWEY & CO.—Gentlemen: My patent is just received, and is entirely satisfactory. Permit me to tender you my sincerest thanks for the care and attention, the promptness and interest you have displayed in managing my affairs. Gratefully yours,

O. F. McALLAN.

SUTTER CREEK, February 26th, 1875.
MESSRS. DEWEY & CO.—I have received my Letters Patent through your agency. And, for your promptness, accept my thanks. Yours,

S. N. KNIGHT.

DEWEY & CO., GENTS.—I assure you there is no more welcome sight to "Our Folks" than the Press, and I had far rather do without my dinner than fail to receive your valuable paper each week.

G. W. O.

Scientific and Practical Books

on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY
OO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the
Extraction of their Respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price \$2.60 coin, or \$3 currency, postage free

Concentration of Orea (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and relied on by its readers, containing as it does, much essential information to the Miner, Mill man, Metallurgist, and other professional workers in ore and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO \$5.

Nevada and California Processes of Silver and Gold Extraction, for general use, and especially for the Mining Districts of California and Nevada, with full explanations and directions for all metallurgical operations connected with silver and gold from a preliminary examination of the ore to the final casting of the ingot. Also, a description of the general metallurgy of silver ores. 1864.

As its title indicates, this work gives a wide range of information, applicable to all vein miners and workers in precious metals, affording hints and assistance of exceeding value to both the moderately informed and the most expert in the art.

Price, \$5 in cloth; \$6 in leather—coin.

BY OTHER AUTHORS.

The Quartz Operator's Hand-Book; by P. M. Randall. 1871. Revised and Enlarged Edition. Cloth bound, 176 pages. Price, \$2.

Sulphurets: What They Are, How Concentrated, How Assayed, and How Worked; with a Chapter on the Blow-Pipe Assay of Minerals. By Wm. M. Barstow, M.D.; 1867; cloth bound, 114 pages. Printed and sold by Dewey & Co. Price, \$1; postage free. The best written work, and most complete work on the subject treated.

ANY OTHER BOOKS DESIRED will be furnished at the most reasonable rates by DEWEY & CO., Mining and Scientific Press Office, S. F.

SECOND EDITION—REVISED AND ENLARGED.

The Explorers', Miners' and
Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy.

Containing 672 Pages and 83 Engravings

BY J. S. PHILLIPS, M. E.,

Of California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE, bound in cloth, \$10.50; in leather, \$12. Forwarded by mail for 50c. extra, at the MINING AND SCIENTIFIC PRESS Office, by

DON'T STOP THE PRESS.—A subscriber in Tulare county, in sending us the renewal of his subscription, adds the following: "Don't stop the Press; I'd just as soon you would stop a portion of my bread. It is a welcome friend to our fireside. Wife is just as deeply interested as I am, and would sooner sacrifice her tea than forego the pleasure of reading the Press. The young Grangers in our family, with sparkling eyes and swift coming feet, gather around to look at the ever new and unfolding wonders to be found in the Press. I repeat it, don't stop the Press." D. W. VIALIA, Nov. 3d, 1874.

CAMPO, SAN DIEGO CO., CAL., July 3d, 1874.
MESSRS. DEWEY & CO.—Gentlemen: To-day I received the patent and other papers of my animal trap, that you so successfully worked through the patent office for me, for which please accept my best wishes. The chances are that I will have another application for you to make for me before long. I am well satisfied with your manner of doing business, and I think inventors of this coast stand in their own light when they do not put their business into your hands.

I remain yours truly, A. M. GASS.

MESSRS. DEWEY & CO., San Francisco:—Please find enclosed post-office order, for which please send MINING AND SCIENTIFIC PRESS. I have been a close reader of the Press for three years, and regard it as the foremost mining periodical in the Union. I am glad to notice the circulation of the Press is increasing here and is highly prized by our best mining men. H. P. Central City, Colorado.

A REAL CONVENIENCE.—DEWEY & CO: Please send me the RURAL PRESS. It is a real convenience and I cannot do without it. Enclosed you will find five dollars. Fraternally, B. F. E. K. Anaheim, Cal., October 12, 1874.

GIANT POWDER.

Its Properties, Uses, and Revolutionizing Success.

Few things have contributed so much to the development of the mining interests of this coast as Giant Powder has done. It was difficult to introduce the substance in the mines here as the miners objected to its use, some on the plea of its supposed unhealthy properties, and some because they supposed it would materially reduce the force of working miners. These foolish prejudices were overcome by force of circumstances, and the process is now universally used and thoroughly appreciated. Its use has increased, as far as we can learn, in any country where it has been actively introduced. Prejudice recedes from it, and it has benefited the mining interests so much that it is now considered an indispensable requisite in all mining operations.

We have given from week to week items from various sources showing the benefits accruing from the use of giant powder of the different grades for different classes of work. It needs no recommendation from us, as its work speaks for itself and the results can be seen everywhere. It is much safer than ordinary powder and when ignited it will burn, not explode, unless exploded by the peculiar caps employed for this special purpose. It was at first supposed to be more dangerous than ordinary explosive compounds, but it is now conceded that its only danger is in its safety—a paradoxical proportion apparently. This is so, however, as some people become so familiar and careless with it as to try all sorts of useless and foolish experiments. Its characteristics are now so well known that none object to using it, and it would be difficult to go back to the old slow way of blasting.

We make some extracts on this subject from a paper on the Musconetcong Tunnel, read by Henry S. Drinker, E. M., before a recent meeting of the American Institute of Engineers, as follows:

It is worth noting what this new explosive, giant powder or dynamite, is. As to its characteristics—first it is tremendously powerful, bringing out at a blast masses of rock that black powder could not even shake, and is simply invaluable for rapid driving in hard rock. How it compares economically with pure nitro-glycerine we are not prepared to state. Containing a percentage of the latter, it is, of course, not so powerful bulk for bulk, but again it has the great advantage of distributing the force over a greater space, which is the underlying principle of much of the deep hole blasting. Again, so far as an explosive can be termed so, it is entirely safe from accident from the proverbial carelessness of workmen, undoubtedly safer by far than black powder, while many times stronger. Hardly anything short of a cap exploded in a cartridge will fire it. Alone, it may be hammered, crushed, or burnt with impunity. Thrown into a stove or set on fire, it simply burns fiercely without danger of explosion. For exploding the cartridges very strong caps of fulminate of mercury are used; those adopted at Musconetcong, we believe, were originally imported from Hamburg. These caps are prepared as electric exploders as follows: First, a small quantity of sensitive powder is dropped on the fulminate, and into this two wires (lying side by side) are inserted, and the caps then filled with melted sulphur. On the spark passing, the sensitive powder is ignited and explodes the fulminate, and the cap being inserted by the blaster into the cartridge of dynamite, the explosion of the cap fires the latter. If firing by fuse, it is simply necessary for the blaster to squeeze the end of a piece of fuse, properly rasped and sharpened, into the cap, and to place the latter in the cartridge. A good electric battery is that manufactured by the Lafin & Rand company, under, we believe, Julius Smith's patent, the condenser and generating plate being of vulcanite, and the parts of the battery so arranged as to render it compact and easily handled.

Dynamite is simply nitro-glycerine mixed with a kind of silicious earth known variously as silicious marl, tripoli, and rotten stone. The peculiar variety of this material best suited for

this use is homogeneous, has a low specific gravity, and is generally composed of the remains of infusoria. So great is the absorbent capacity of this earth that when in a pulverized condition, it is claimed by Nobel that it will take up about three times its own weight of liquid nitro-glycerine, and still retain the form of a powder. Any mineral, or indeed vegetable, substance susceptible of pulverization or comminution, and which will retain nitro-glycerine by absorption may be substituted for infusorial earth in the manufacture of dynamite but the latter has so far been found to excel all other substances tried in possessing the requirements necessary; being composed of minute tubular shells, it is light and absorbent. A mass of it is very spongy and compressible, its shells absorbing the nitro-glycerine by capillary action, and holding it with almost absolute security against filtration or compression. The secret of the safety of this powder seems to be in its soft, pulpy, and at the same time mealy consistency, which gives it a complete cushion to prevent percussion, as a blow upon it seems like a blow upon a bag of meal; the greater the quantity the more the compressibility, and the greater the safety.

In an admirable paper on dynamite, read by Captain Alex. Mackenzie, of the Corps of Engineers, before the Essayons Club, in February, 1874, he gives his experience of a visit to the works of the company in Morris county, N. J. He says: "The infusorial earth or kieselguhr was originally all imported from Germany, out beds of it were subsequently found in the vicinity of the works, in New Jersey. No. 1 powder is composed of seventy-five per cent. nitro-glycerine and twenty-five per cent. infusorial earth, made into cartridges one and three-eighths inches in diameter by eight inches long. No. 2, of thirty-six per cent. nitro-glycerine, forty-three per cent. nitrate of potash, seven per cent. rosin, seven per cent. sulphur, and seven per cent. infusorial earth, comes in cartridges one and one-half inches in diameter by eight inches long. The size of these cartridges may be varied to order. In manufacturing No. 1 powder, the kieselguhr is prepared for use by first mixing it with a little water and baking into bricks for thorough drying. The bricks are then ground and mixed with nitro-glycerine. In preparing the absorbent or dope for No. 2, the sulphur is pulverized in a revolving cylinder, at one end of which a blast of air enters, and, passing through, carries the powdered sulphur into a tight box. The nitrate, either of soda or potash, is first dried thoroughly on an iron floor, then ground in a mill and passed into a box. The rosin is pulverized in a cylinder. The sulphur, nitre, rosin and earth are then mixed in proper proportions. In making the nitro-glycerine, the following proportions are used: Two parts of anhydrous acid are mixed with one part of nitric acid. For every seven parts of the mixed acids one part of glycerine is added. One part of nitro-glycerine is expected for every four parts of the mixed acids. The relative strength of No. 1 and 2 powder has not yet been definitely determined practically by any series of experiments, but it may be calculated as follows:

No.	Composition.	Relative strength of components	Relative strength compared with nitro-glycerine.
1	75 per cent. nitro-glycerine, 25 per cent. kieselguhr.	75 per cent.	75 per cent.
		50 per cent.	
2	36 per cent. nitro-glycerine, 64 per cent. potash, sulphur.	36 per cent.	68 per cent.
		32 per cent.	

"It is claimed that, though the absorbent of No. 2 has really but little strength within itself, it develops, when fired by nitro-glycerine, about one-half the strength of nitro-glycerine pure."

With reference to the direct connection of this explosive with tunnel work, the advantage gained by its use is based especially on the great saving of time, which is an object in all work. Taking pound for pound, it is more costly than black powder; but it should be remembered that its explosive force is also many times as great. Berthelot, in his researches on explosive matters, calculates from the chemical composition of the explosive the volume of the gases produced by the explosion, and the quantity of heat produced in the reaction. The product of the two numbers, as he conceives, giving within certain limits the explosive force, Berthelot's estimate gives the

ratio of ordinary blasting powder to pure nitro-glycerine, as 83 to 939, or that nitro-glycerine is 10.7 times stronger, taken in equal weights. This estimate, applied to dynamos, would make No. 1 eight (8) times stronger than blasting powder, and, if we accept the estimate of 68 per cent. as the relative strength of No. 2, it would make No. 2 seven and three-tenths (7 3-10) times stronger than blasting powder. The questions to be considered, in reference to the adoption of dynamite, would of course be governed by considerations of time, location of work, character of rock, etc. Where the material is soft, dry rock, which can be attacked from several points at once, and in cases where the speedy completion of the work is not the most important element to be considered, probably black powder, at present prices, would be the cheaper agent; but, again, taking the case of a tunnel where the blasting, like that at Musconetcong, is for the greater part through hard, wet rock, which can only be attacked from two headings at a time, and where a heavy outlay of capital lies dead until the completion of the work, the advantage of using so speedy, and yet so safe, an agent is most manifest.

The introduction of dynamite has already revolutionized tunnelling, and, hand in hand with machine drilling, is doubling and trebling the old rates of progress attained by hand drilling and black powder.

Now, before taking up the east heading, we will consider in a few words the enlargement in rock of west heading No. 1. This "bench," as the rock enlargement is termed, was kept both on the east and west sides from four to six hundred feet back of the headings, so avoiding any interruption at the bench from heading blasts, and allowing plenty of room for handling and switching cars, also for backing the machine to a safe distance from the face when blasting, etc. In taking up the west bench there was no extraordinary detention; the work was begun January 1st, 1874. Owing to various detentions, its steady advance did not commence until July, 1874. Up to that time, though the headings were of course free from water, the flow remained so great that frequently the enlargement, on the shortest stoppage of the pumps, would become flooded several feet in depth; also, until the headings met, in December, 1874, both the west and east enlargements were detained by the time lost in removing the broken rock from the headings. This was run out from the top heading on a movable bridge extending over the men at the bench, and ending in a chute, into which the cars were dumped. From this chute the rock was again loaded on cars in the bottom and run out to the slope. Every time, therefore, that a blast was fired this bridge had to be run back, and then up again to the face as soon as the track could be cleared, much time being often lost in the operation from unavoidable detentions that frequently arose. The different stages of progress attained in running a bench with a heading in front, and after the headings are cleared, the average monthly advance was raised in the west enlargement from 87 feet, in 1874, to 188 feet, in 1875, on the meeting of the heading in December, 1874; the increase in the east enlargement being from 96 feet, in 1874, to 181 feet, in 1875.

These two sets of holes, top and bottom, will average a linear advance for the bench of 9 feet, the following being a fair estimate for that advance of the number of feet drilled and powder burnt:

	No. of Holes	Depth of Holes	Total Depth of Holes	Lb. No. 2 Dynamite.
Top Holes.....	6	12 ft.	72 ft.	62 lb.
Bottom Holes.....	4	10 ft.	40 ft.	45 lb.
Totals.....	10	21 ft.	112 ft.	107 lb.

The total height of the cross-section adopted for the tunnel through hard rock, from lower sub-grade (1.75 ft. below base of rail) to roof, was 22.15 feet; with an 8-foot heading off, this leaves about 12 feet of a bench, with an area of 306 square feet, which gives about 102 cubic yards to a linear advance of 9 feet, or 1.05 pounds No. 2 dynamite, and 1.1 feet of holes drilled to one cubic yard of rock broken, holes being drilled with from 1 1/4 to 2 3/4-inch bits, the largest bit being put in first. In general, three machines are kept in use at the bench, two on top and one below; to run them, 3 drillers and 3 helpers are needed, about 44 laborers to clear away rock, one nipper, and a boss.

Before speaking of the east end, it may be well to state that the enlargements in rock of No. 2, or the heading driven west from the slope, was not pushed during the foregoing work, there not being the same necessity for haste in pushing its progress. After passing the junction of headings No. 2 and 3, it was driven on to a point about 175 feet from the slope. There the rock giving out, the enlargement in earth, to be followed by arching, commenced.

In this tunnel at Musconetcong, giant powder was adopted as an explosive by Mr. McFadden and the blasting was done by cuts. This method of blasting by cuts is based, of course, on the extraordinary force developed by a comparatively small bulk of explosive matter. It consists in first blasting out an entering wedge or core, about 10 feet deep at the center, and subsequently squaring the sides by several rounds. To do this, first 12 holes are drilled by the six machines, three on one side. These 12 holes are drilled two and two, six on a side, with from 1 1/4 to 2 3/4-inch "bits," the two sets being started about 9 feet apart, and at such an angle as to meet or cross at the bottom, the largest bits being put in first. They are then charged with about 25 lbs. No. 1 and 59 lbs. No. 2 giant powder, and fired simultaneously by electricity. No. 1 is only used for cuts, inasmuch as in them a quick, strong powder, comprised in a small bulk at the bottom of the holes, is required, where the greatest resistance will be found, while the No. 2 added, serves in filling the holes, so starting the sides of the cut as the apex moves. The cut being out, a second round of holes is started for the first squaring up. In these, and in the subsequent rounds, the resistance is pretty equally distributed along the whole length of the holes, and is also, of course, not so great as in the cut; therefore, No. 2 is used, as in it the nitro-glycerine is mixed with a larger proportion of absorbent matter and the force is thereby distributed over a greater space.

In the first and second squaring up rounds, from fifty to sixty pounds of No. 2 are charged, and in the third, from eighty to ninety, the holes getting stronger as the arch falls at the sides; there are generally also one or two additional roof holes in the third round, their position being variable, according to the lay of the rock. The top holes in the first round are also designed to bring down any roof not shaken by the cut, and are, therefore, given a strong angle towards the center, and always drilled from twelve to fourteen feet deep. As to their relative depth, the holes of the first squaring round are always drilled a foot or more deeper than the cut holes, and when blasted they generally bring out a foot additional of shaken rock at the apex of the cut.

Allowing the cut holes to be 10 1/2 feet deep, the cut will generally blast out about 9 full feet linear, which is raised to ten in the subsequent rounds.

Assuming the average cross-section in an eight-foot heading to be about 175 feet, for a linear advance of ten feet, 65 cubic yards of rock would be broken, which would give an average of, say, four-tenths (.4) lb. No. 1, and four (4) lbs. No. 2 giant powder burnt, and a little over six feet of holes drilled, per cubic yard broken.

The agents of this powder in San Francisco, Messrs. Bandmann, Nielsen & Co., No. 210 Front street, will give any further information on the subject to those desiring it.

This, however, it should be noted, would often be increased by occasional block or side holes, and is assumed for a case in which no holes are supposed to have missed, and in which no secondary drilling and blasting is required. Proportionate amounts would have to be added for such cases.

The above estimates are based on ordinary ten feet cuts; there were, however, many instances of 12 and 13, and sometimes 14 feet cuts taken out by ambitious foremen, but even giant powder has its limit of strength, and working too deep cuts is not advisable, as they will often only blow out partially, leaving the rock in awkward shape. As to the division of time in heading work, to drill and square up a cut should take about four eight-hour shifts, with such rock as was met Musconetcong, it being, as stated, unusually hard and tough.

It will take one shift to drill and blast the cut and one shift to each of the three rounds, and this with a force of 12 machine men (one driller and one helper to each machine), 6 laborers for loading broken rock, 1 nipper for car yard tools, a boss. On an average, however, this standard will hardly be reached, as it provides for no stoppage, no missed holes, and no accidents, and unfortunately, tunnel headings, like all things earthly, are liable to occasional stoppages and accidents.

SAFE INVESTMENT.

The Pacific Coast Twelve Per Cent.
Consols.

NEW METHOD WITH ASSURED ADVANTAGES.

A rapidly growing interest is being taken in the Pacific Coast Twelve Per Cent Consols, in consequence of the many advantages offered in regard to investment, interest and dividends. So much uncertainty exists in connection with nearly all mining and other speculative companies, there is something very assuring in an incorporation which not only guarantees twelve per cent. per year to all stockholders, but provides for the honest payment of dividends. The Twelve Per Cent. Consols were incorporated on the 12th of February last, for the purpose of transacting a general business in buying and selling mining properties, city real estate, and agricultural and other lands, in the States and Territories of the Pacific Coast. Determined to do only a strictly legitimate business, the Directors rejected the old method in vogue by mining companies generally, and adopted a new one which secures to all parties who become shareholders, equal advantages in the business transacted. By the provisions of the by-laws,

A Sinking Fund

Is to be made of one-half the proceeds of the total capital stock, which shall be sold on the joint account of the original co-owners. The stock will be classified as follows: Sinking Fund, mining property, city real estate and agricultural lands. Before any stock is issued in any class, the property will be appraised by the owners, and the stated value entered upon the books of the Company. Shares for not more than fifty per cent. of the valuation will be issued in any of the classes, and the amount of shares offered for sale in any one class, exclusive of the sales of stock in the Sinking Fund, will not be allowed to exceed 50,000, if sold at less than the par value of a dollar per share.

Guarantees of Safety.

In regard to the Sinking Fund, which will constitute fifty per cent. of the par value of the stock, all moneys received as the proceeds of sales of stock on account of the fund will be deposited with some solvent banking institution, which pays interest on deposits invested in interest bearing stocks, bonds and securities, which can be realized on in thirty days, and in no case will it be lawful for the directors or trustees to invest any moneys of the Sinking Fund in the purchase of stocks, bonds or other securities of any incorporation whatever, which shall have failed to pay interest or dividends for a period of six months preceding any proposed investment pertaining to the Sinking Fund of the Company.

Payment of Interest.

The by-laws further make positive provision for the payment of interest monthly on all stock issued in each class at the rate of twelve per cent. per annum, payable on the 5th day of each month. Another important concession is that any shareholder has the option to take stock in payment for interest at par value in any class that may be preferred. No assessment will be levied until the total stock of the Sinking Fund shall have been sold and paid out as provided by the by-laws. Indeed, so secure is the plan of the Company that in case the whole capital stock of the Company should be sold immediately and the Sinking Fund invested as provided, the proceeds would be sufficient to pay the interest for eight years and a half on the total capital stock. Perhaps no other company in the world has ever been able to present so brilliant a certainty.

Dividends.

Stockholders will not only be sure of their twelve per cent. per annum, but will share in all the surplus profits. The dividends will be paid from the profits and assets of property, and only on shares of consols that have been issued for property valued and entered on the books of the Company. As there can be very little question that the transactions of the Company will be very extensive, and that the profits will rapidly reach something handsome, the dividend prospect should serve as a strong inducement to stock purchase, for perhaps in no other direction can they be positive of receiving one per cent. a month for money invested, and almost a certainty of large yearly dividends in addition.

A further provision can be made at any time by the Company by setting aside the percentage agreed upon of the sales of the properties of the Company. The main object of the directors is to incorporate a more legitimate and assured method of transacting business in mining and property than has hitherto obtained on this coast. They are therefore resolved to touch nothing but bona fide investments, and to make it a rule to have nothing to do with speculative values. Every possible care will be taken to protect the interests of shareholders, and in order that they may be constantly posted in the transactions of the Company, a monthly statement of affairs will be prepared by the officers, and the books will be at all times open for inspection. Shares for the first series issued for mining property in Washoe, Storey and Lyon counties, and on the Consolidated Nevada, and for account of Sinking Fund, will be ready for delivery to shareholders and purchasers to-morrow, at Greenbaum & Co.'s, 306 Montgomery street. The set selling rate will be one-twenty, and the buying rate one-nineteen. The principal office of the Company is at 506 Montgomery street. T. Phelps is the President, and W. S. Reynolds the Secretary.

QUICKSILVER.
UNITED STATES PATENT OFFICE.

The Quicksilver Mining Company of New Almaden, California—Trade-mark for Quicksilver Flasks. Statement of trade-mark No. 1499, registered October 19, 1873; application filed September 29, 1873. Specification describing a trade-mark, used by the Quicksilver Mining Company, a company chartered by the State of New York, and working and operating quicksilver mines at New Almaden, Santa Clara county, State of California, for Quicksilver Flasks.

Our trade-mark consists of the letter "A" straddling a circle. This letter has generally been painted upon the upper end of each flask, bottle, or jar in which the quicksilver is contained, its usual position being such that the opening or mouth in the upper end of the flask, bottle or jar will be between the spreading angular sides of the letter, the cross-mark of the letter passing along close to the edge of the hole.

This trade-mark we have used in our business for ten years last past. The particular goods upon which we have used it are quicksilver flasks, and it has always been applied as above described.

THE QUICKSILVER MINING COMPANY.

By J. B. RANDOL, Manager.

This trade-mark is also registered in the office of the Secretary of State, Sacramento, California, and all producers and dealers in quicksilver are cautioned not to use the said trade-mark.

For New Almaden Quicksilver, apply to THOMAS BELL, Sole Agent, Over Bank of California, San Francisco.

NEW ALMADEN QUICKSILVER.

TRADE MARK.

The well known full weight and superior quality of the quicksilver produced at the New Almaden Mines having induced certain unscrupulous persons to offer their inferior productions in flasks having our trade-mark, "A," notice is given to consumers and shippers that quicksilver, "A" brand, guaranteed weight, can be purchased only from THOMAS BELL, San Francisco, or his duly appointed sub-agents.

J. B. RANDOL, Manager, New Almaden, April 5, 1875.

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.

It is unequalled for dissolving Woolen Fabrics, Cottons, Carpets or Crockery; for scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Sizing.

It renders water soft, and imparts a delightful sense of coolness after washing.

DIRECTIONS.—For Laundry, use two to four table-spoonfuls to a wash tub of water. For bathing, use one table-spoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterward. For stimulating the growth of plants, use a few drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents. Also, BULPHATE OF AMMONIA, for chemical purposes, fertilizing, and the preparation of artificial manures, AMMONIACAL PREPARATION, for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing, and FUR LICKER AND ADON, AMMONIA for chemical and pharmaceutical purposes.

JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pulp being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco

Copyrights.

Our patent laws are based upon the proposition that the originator or producer of anything new is entitled to a certain proportion of the benefit to be derived from his production. This rule is also applicable to literary productions, and the term which is employed to designate this class of protection is called a copyright.

Copyrights are only granted to citizens of the United States or residents therein. A foreigner cannot secure the copyright protection in the United States, neither does any foreign country grant the right of a copyright to citizens and residents of the United States. The only way for an American citizen to secure his right to a literary production in a foreign country is to engage some resident of that country to secure the protection and hold it for him. Many attempts have been made to inaugurate an international copyright law, or system by which the producers and authors of literary productions could secure universal protection for their works, but as yet all attempts to accomplish this result have failed.

The copyright protection is granted to "the author, inventor, designer, or proprietor of any book, map, chart, dramatic or musical composition, engraving, cut, print or photograph or negative thereof, or of a painting, drawing, chromo, statue, etatuary, and of models and designs intended to be perfected as works of the fine arts," and the law adds that the executors, administrators or assigns of the author, originator or designer shall have the sole liberty, upon complying with the law, "of printing, reprinting, publishing, completing, copying, executing, finishing and vending the same; and in the case of a dramatic composition, of publicly performing or representing it, or causing it to be performed or represented by others, and authors may reserve the right to dramatize or translate their own works."

Thus the protecting arm of the law is thrown around men of genius and literary attainments, and they are allowed the benefit of whatever merit they possess, in return for the benefit which they confer upon the public. Many a well deserved fortune has resulted from the possession of a copyright.

In Order to Secure a Copyright

The proprietor is required by law to mail a printed copy of the title of the book, or a written description of the thing to be copyrighted, to the Librarian of Congress at Washington before the publication of the work. And within ten days after publication he is required to mail to the Librarian of Congress two complete copies of the work to be protected. The word "publication" has been held to mean "sale" in this connection, so that the two copies must be deposited in the mail within ten days after one of the copies is disposed of by sale.

In many cases copyrights have been secured without the preliminary step of mailing to the Librarian of Congress the title page or a description of the work. We doubt whether such a copyright would be legal. The Librarian of Congress issues the usual certificate upon the payment of the proper fee and the deposit of two copies of the work, but the fact that a certificate has been issued is not a proof that the proprietor has complied with all points of the law and that the copyright is complete and legal.

If it be established in any suit which involves the validity of a copyright that this preliminary title page or description was not properly placed on file before publication of the work, I do not see how the courts can fail to pronounce the copyright as incomplete and therefore void.

If a person places on file the title page or description of a work and fails to complete the copyright by filing two sample copies of the same as required by law, he is liable to a penalty of twenty-five dollars.

The preliminary filing of the title page or description of the work to be copyrighted is intended to serve as a caveat to protect the proprietor while he is engaged in perfecting and publishing his work. Several notable instances have occurred where a written article or poem was published anonymously and it was afterwards found almost impossible to prove who the author was amidst a number of claimants all of whom had equal grounds upon which to establish their claims. The author can now easily avoid such trouble by filing his intention before he gives his work to the public. Every copy of the copyrighted work must contain a conspicuous notice that a copyright has been secured, and this may be done by either printing, engraving or stamping upon each copy the words "copyright secured by A. B. in 1875" or "copyrighted by A. B. in 1875." The law of 1870 made it the duty of every proprietor of a copyrighted work or article to place upon each article the words, "Entered according to the act of Congress in the year — by A. B., in the office of the Librarian of Congress, quicksilver, also, as I believe, by chemical action. And I might mention other chemical reactions, causing loss of quicksilver. Hence the importance of keeping the pan as clean as

possible of quicksilver in the first half of the at Washington." This notice, however, was found to be cumbersome and its use in many instances impracticable.

The law was therefore amended in 1874 so as to render the words "copyrighted" or "copyright secured" legal. They are certainly as explicit and much more convenient than the former lengthy notice.

A copyright can be assigned by any instrument of writing in the same manner that patents are assigned, and all assignments of copyrights must be recorded in the office of the Librarian of Congress within sixty days, in order to protect the assignee from subsequent purchasers.

Copyrights are granted for a term of twenty-eight years from the time the title is recorded in the office of the Librarian of Congress, and at the expiration of this term, the copyright can if he be living, or if he be dead his widow or children can, have the right extended for a further period of fourteen years.

It is a public offence for any person to mark any production or work with the words "copyrighted" or other words of like import, which has not been secured by a copyright, and the law in regard to the infringement of a copyright, either by copying, printing or making a fac-simile of the thing copyrighted or so close an imitation thereof as would be calculated to deceive the public, or with intent to evade the right of the proprietor, is very strict, and the rights of proprietors are carefully guarded.

Labels.

This term label is intended to include printed instructions, wrappers of articles upon which descriptions are printed and the ordinary labels which are permanently secured to or upon articles of merchandise. The principal use of labels is upon bottles containing patent medicines or composition articles. Heretofore this class of printed matter has been copyrighted in order to secure its protection, but the law in relation to labels which went into effect in August, 1874, provided for the issue of a patent or certificate of registration for their protection, in the same manner that trademarks are protected. Applications for patents on labels must now be made to the Commissioner of Patents.

NOTE.—These lectures will be issued in cheap book form by the publishers of this journal.

Fatal Mining Accident.

On the 21st inst. a frightful accident occurred at the Murohie mine near Nevada City. About half past three o'clock the roof of the hoisting works of the mine was discovered to be on fire, just above the engine. John Shaw and another man were the only men on the top at the time. There were six men at work in the shaft, which is 400 feet deep; their names were Samuel Hecker, John McCourt, Jack Stephens, Thomas Jenkins, Daniel O'Donnell and a Chinaman. Mr. O'Donnell made his escape. He says the Chinaman told him that he was wanted above. He asked the Chinaman why the ore was not hoisted. The latter said he did not know. The rope kept jerking, which was a sign that there was something the matter. O'Donnell started to go to the surface, and thinks the others attempted to follow about 100 feet behind him. When he got in sight of the top, he saw men beckoning him to come up. He hallooed to the others and moved on himself. When he reached the top, the building was all on fire, and the three sets of timbers in at the mouth of the shaft also on fire. Pieces of the burnt shingles were falling thickly in the building, but he pushed through the hot flame and smoke and reached the outside, completely exhausted. There was a large pile of timber around the building, which also took fire and made the heat intense for a hundred feet around. There was no water nearer than the V flume, a half mile or more distant. Men were sent to that place, and at about half past four o'clock it reached the fire.

As soon as it came, men took pails, pans and everything within reach, and commenced to dash water on the pile of wood and down the shaft. The fire at the mouth of the shaft was soon extinguished, and O'Donnell, the man who had escaped, put a rope around him and descended into the smoking mine underground. He went down about twenty feet and found McCourt with his feet caught in the ladder. He at length released him and was drawn out, about smothered himself. McCourt was breathing when brought to the surface, but died in a minute after. O'Donnell said there was not a particle of air at the depth of twenty feet when he was down there, but the shaft was full of smoke.

After the fire had been partially extinguished, a hells was obtained, and air pumped down. O'Donnell, who was the hero of the hour, again descended, with others, and found Hecker and Jenkins about one hundred and ten or twelve feet down the shaft. Hecker was dead, and Jenkins nearly so. They were taken to the surface, and it was hoped that Jenkins might recover, although the chances were slight. Stephens and the Chinaman had got up to the same point, but finding the air stifling, got down the pump rod until they found good air, where they were found all right.

It is reported that about the 1st of July a cargo consisting of 12,000 ties and the first consignment of railroad iron will arrive at Santa Monica.

Hints on the Washoe Process.

(Continued from last week.)

The Loss of Quicksilver.

Every piece of wood that has come in contact with quicksilver, the canvas straining secks, the worn out pan shoes and dies, even after careful washing and breaking, the thoroughly washed and shaken quicksilver flasks, the used up kettles and dippers, the floors, &c., all have quicksilver sticking to them; the men carry quicksilver on their boots and clothes, and it is found scattered in very small quantities outside of the mill. It goes everywhere. Drop a globule on the floor, you cannot entirely recover it. Climb up forty or fifty feet to the cross timbers in the top of the mill, collect some dust on top of the timbers, examine it with a glass or wash it, and you will find quicksilver. Some is lost every time crude bullion is melted. Every pound of quicksilver is banded probably forty times a day, and every time there is a little loss. (Quicksilver should be handled as much as possible mechanically, being raised by steam in pipes or some other arrangement.) Quicksilver not covered with water or other liquid evaporates in the air. These losses can only be prevented partially by the greatest cleanliness and care.

Again, quicksilver charged with copper readily becomes coated with small particles of iron. In the pulp, it is readily coated by iron pyrites, greese, elimes, etc., or reduced to great fineness by grinding. In these "flooded" and coated conditions much of it will float away and be lost, unless means are employed to collect it. I have found cyanide of potassium very effective for this purpose. Thorough settling also collects a good deal. Ores containing much tale likewise act unfavorably on quicksilver. As soon as quicksilver is flooded, and becomes sluggish, it not only loses to a large extent its amalgamating power, but also is easily cut up and flooded.

In addition to the sources of mechanical loss above mentioned, much of the quicksilver is lost chemically. The water from the settlers, if filtered and concentrated, will show quicksilver present in solution. Sulphate of copper in solution is decomposed by quicksilver, some of the quicksilver becoming sulphate of mercury, while the precipitated copper forms a copper amalgam with the remaining quicksilver. Chloride of silver also can be decomposed by quicksilver, chloride of mercury being formed. If binoxide of manganese is present in the ore, it occasions a heavy loss of period of working the charge. The grinding in the first half will not cut up and flour the quicksilver; the chemicals can act on the ore and not on the quicksilver; and the silver minerals will be reduced by the chemicals, instead of having the expensive quicksilver consumed by reducing some of the minerals or combinations. By observing this simple rule, by using chemicals for saving quicksilver at the end of the charge, and by subsequent careful settling, I have found it possible to diminish very much the loss of quicksilver that would otherwise occur.

In conclusion I have only to say, that, in my opinion, even base and refractory ores can frequently be worked more profitably by this process than by the vastly more expensive methods of dry crushing, roasting, smelting, etc.

Much of the credit to be given for many points brought forward in this paper is due to Mr. William F. Carter, mechanical engineer, who has worked with me constantly for several years past.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

(FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

By Special Dispatch, Dated Washington, D. C., June 22d, 1875.

FOR WEEK ENDING JUNE 8TH, 1875.

DYNAMO WRENCH.—Sebastian Plym, Portland, Oregon.

FIRE ESCAPE.—Franklin P. Berney, San Quentin, Cal.

MANUFACTURE OF NITRO-SULPHURIC ACID FOR MANUFACTURING NITRO-GLYCERINE.—Prudencio Castellanos, S. F., Cal.

RECOVERING ACIDS FROM RESIDUUM OF NITRO-GLYCERINE MANUFACTURE.—Prudencio Castellanos, S. F., Cal.

APPARATUS FOR RECOVERING ACIDS FROM THE RESIDUUM OF NITRO-GLYCERINE MANUFACTURE.—Prudencio Castellanos, S. F., Cal.

EXPLOSIVE COMPOUNDS.—Prudencio Castellanos, S. F., Cal.

EXPLOSIVE COMPOUNDS.—Prudencio Castellanos, S. F., Cal.

LOCK MORTISING MACHINE.—Charles J. Hndee, S. F., Cal.

HYDRAULIC ELEVATOR.—Philip Hinkle, S. F., Cal.

WAGON BRAKE.—John C. Trullinger, Portland, Oregon.

TRADE-MARK.

FOR PREPARED SALMON.—James Quinn, Portland, Oregon.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening last, Vice President Gibbons in the chair. The donations to the museum consisted of specimens of teal duck, pine cones, minerals from Governor Purdy, and several valuable specimens of wood from Professor Davidson, in Japan; quicksilver and other mineral specimens from gentlemen whose names were not ascertained. Dr. Gibbons, of Alameda, read a paper on a specimen of the trout fish found in Mendocino county. Judge Hastings submitted three papers: "A Plan for the Reclamation of Swamp and Overgrown Lands," "Artificial Rains," and the "San Francisco Observatory." Dr. Kellogg read a brief paper on "The Oregon Lily."

Mr. Amos Bowman read a paper on "The Great Plunge of the Tertiary," which is given in another column.

It was announced that the proceedings of the Society for last year were published and ready for distribution.

Work on the Nevada County narrow gauge railroad is progressing rapidly. When completed it will be one of the best of narrow gauge railroads—first-class in all respects. Mr. J. F. Kidder, the engineer of construction, states that the tunnel between Bear river and Greenhorn creek will be completed by the middle of August.

THE *Argus* thinks that Petaluma presents great inducement for the establishment of extensive tanneries. There is an inexhaustible supply of bark in the county, a near market, cheap transportation, excellent climate and all the facilities and advantages that could be desired.

THE grading of the Ruby Hill and Enreka railroad has been completed to the Lawton dump of the Enreka Consolidated line. The surveyors are now engaged in running track centers, and will soon finish their part of the work. Iron and ties are arriving daily and being laid.

A \$4.00 BOOK FOR \$1.50.

The People's Common Sense Medical Adviser, in plain English, or Medicine Simplified, by R. V. Pierce, M. D., Counsellor-in-Chief of the Board of Physicians and Surgeons at the World's Dispensary, Buffalo, N. Y. The above work—a book of about nine hundred large pages, profusely illustrated with wood engravings and colored plates, and well and strongly bound—will be sent postpaid to any address for One Dollar and Fifty Cents, making it the cheapest book ever offered to the American people. Other books treating of domestic medicine, of like size and style of binding, and not nearly as well illustrated, with no colored plates, and some of them containing no prescriptions, and making known no means of self cure for the diseases which they discuss, sell for from three dollars and a half to five dollars. Were Dr. Pierce's Work not published by the author, printed and bound with his own machinery, and were it sold through agents, as other like works are, the price of it would have to be not less than four dollars. For when the publisher pays the author a fair price for his production, then adds a profit to his investment large enough to satisfy himself and compensate him, not only for his labor, but also for the risk of pecuniary loss which he assumes, in taking the chances of the enterprise proving a success, and when the State, county and canvassing agent has each received his profit, they have added to the expense of a book, that originally cost about \$1.25, so much that the people have to pay not less than \$4.00 for it. The People's Medical Adviser, on the contrary, is placed within the pecuniary reach of all classes by the author, who adopts the plan of the Grangers, depending with middlemen and giving the benefit of their profits to the people, offering his book at a price little above actual cost of publication. That those desiring the book may run no risk of losing their money, in sending it through the mails, the author advertises that money addressed to him at Buffalo, N. Y., and enclosed in registered letters, may be at his risk of loss. The author's large correspondence with the people upon medical matters, which we are credibly informed frequently exceeds three hundred letters a day, and requires several trained and skillful medical assistants and short-hand reporters to enable him to entertain and answer them, as well as his large daily dealings with disease at the World's Dispensary, appear to have peculiarly fitted him for writing the work, by rendering him very familiar with the every day medical needs of the people. He endeavors in this work to answer all the numerous questions relating to health and disease that have been addressed to him by the people from all parts of the land, and hence it contains important information for the young and old, male and female, single and married, nowhere else to be found. All the most prevalent diseases of both sexes are also plainly and fully considered and means of self cure made known. Unlike other works on Domestic Medicine, it includes the subjects of Biology, Cerebral Physiology, Hygiene, Temperaments, Marriage, Reproduction, etc., all of which are treated in an original and interesting manner. It is a compendium of Anatomical, Physiological and Medical Science, and embodies the latest discoveries in each department.—*Com.*
